THE

ENGLISH CYCLOPÆDIA.

ARTS AND SCIENCES.

COIN: metal stamped for currency, or in commemoration of some event, in which latter case the coin are frequently distinguished as medals. With the ancients, however, the coins used for currency had occasionally this property of the modern medal. [MEDAL.] The word coin is derived by some from the Greek *κόινος, common;* by others from the Latin, cuneus, *a wedge;* the first currency of metal, in all probability, being in the form of wedges, or ingots. Commerce, in the earliest periods, was carried on by the mere exchange of articles, and it is remarkable that throughout the early part of Scripture, as well as through the poems of Homer, not a single passage occurs from which we can infer either the use or the existence of stamped money. Metals, however, being close and compact in form, universal as to use, and admitting of division into larger or lesser parts, soon became the representatives of value, though at what exact period remains in doubt. Herodotus, i. 94, speaking of the Lydians, expressly says they were the first people on record who coined gold and silver into money. The Parian Chronicle, however, ascribes the origin of coined money to the Æginetans, under Pheidon, king of Argos, 895 years before Christ. Ælian, in his 'Various History,' corroborates this statement as far as the Æginetans are mentioned: and our best numismatic antiquaries agree in considering the coins of Ægina, from their archaic form and appearance, as the most ancient known. They are of silver, and bear on the upper side the figure of a turtle, and on the under an indented mark, as if the metal, at the time of striking, had been fixed upon a puncheon, and from the weight of the blow had received a deep cleft. In later coins of Ægina, the turtle has been changed to a tortoise, and the fissure on the other side converted into a device. The coins of Lydia probably come next in point of antiquity, and then the early Darics of the Persian kings, which occur both in gold and silver, and bear a strong resemblance to the coins of Ægina in the mode of striking: these, if they are to be referred to Darius the First, must have been coined between B.C. 522 and 486. The richer the metal, the smaller and more portable was the quantity required for the coin. There are coins in gold of the early kings of Persia, similar in type to the silver Darics, and of very minute size.

Gold Daric.

The study of coins is not to be considered as the province of the antiquary alone. Coins are among the most certain evidences of history. In the later part of the Greek series they illustrate the chronology of reigns. In the Roman series they fix the dates and succession of events. Gibbon observes that if all our historians were lost, medals, inscriptions, and other monuments, would be sufficient to record the travels of Hadrian. The reign of Probus might be written from his coins. In illustrating the history and chronology of sculpture and ancient marbles, coins enable the scholar and the artist not only to discern those peculiarities which characterise style, as it relates to different ages and schools, but to ascribe busts and statues to the persons whom they represent. The personation of the different provinces, too, forms another point of interest upon the Roman coins. Coins are frequently essential to the illustration of obscure passages in ancient writers; and preserve delineations of some of the most beautiful edifices of antiquity not existing now even in their ruins. Addison, in his 'Dialogue on the Usefulness of Ancient medals,' has long convinced the world of the connexion of this science with poetry. As a branch of the fine arts, it may be sufficient to say that some of the medals of Sicily belong to a period when sculpture had attained its highest perfection. We would particularly refer to the coins of Syracuse. In every quality of art, too, the Roman coins, to a certain period yield to the Greek alone. From Augustus to Hadrian the Roman mint was the seat of genius: and coins of admirable execution are found even down to the time of Posthumus.

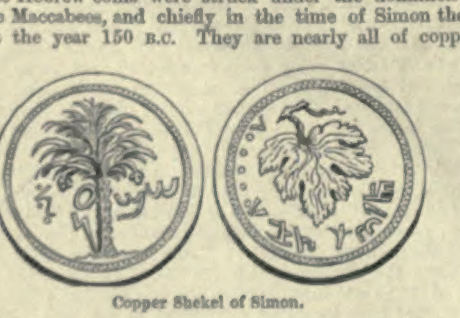
The generality of numismatic writers divide coins into Ancient and Modern;—the Ancient, into the great divisions of Greek, Roman, and Barbarian.

The *Greek* they divide into cities and kings. Of the first they can make no chronological arrangement: it is alphabetical, under the different countries. The kings commence with the age of Alexander the Great, and belong to the four kingdoms into which his empire was divided, besides the kingdom of Epirus. This series, in a chronological point of view, closes with the extinction of the dynasty of the Lagidæ in the Augustan age. The coins of the Greek cities were impressed either with appropriate symbols or the heads of deities. The coins of the monarchs bore the heads of the respective princes. Pinkerton observes that the first copper coins of Greece known are those of Gelon king of Syracuse, about 490 years before our æra. These were called Chalci, pieces of brass; others, of a more diminutive size, were called Lepta, or Kerma, as being change for the poor. He considers there is no proof of the coinage of gold in Greece before Philip of Macedon. Athens had no gold money at the beginning of the Peloponnesian war.

The *Roman* coins are divided into consular, imperial, and medallions. The subdivisions of the consular are into Roman ases and coins of the families. Of the imperial there are two subdivisions, Roman and Grecian; the latter being again subdivided into those of provinces, colonies, and municipia. The medallions are likewise divided into Roman and Grecian. The earliest coinage of Rome was of copper, and took place in the reign of Servius Tullius, probably about five centuries before Christ. The Romans are supposed to have borrowed the art from their neighbours, the Etruscans. Of the as, its divisions and its compounds, we have already spoken in a former article. [AS.] On some of the later Roman, as well as on what were called the Italian ases and their parts, the practice became prevalent of placing the names of many of the principal families of Rome upon the fields of the coins. These form the division which are called family coins. The silver coinage of Rome was introduced in the year 266 B.C., when the denarius was so termed from its being equivalent to ten ases. Pliny informs us ('Nat. Hist.' xxxiii. 13, edit. Hard. ii. 612) that the coinage of gold was introduced sixty-two years after that of silver. The largest piece of gold was called aureus. [AUREUS.] The imperial coins of Rome form the most complete and most interesting series of any extant.

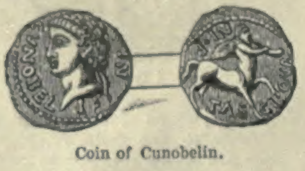
Those of copper being found of different sizes, are distinguished into first, second, and third brass; in historical importance as well as for the devices, the largest series is to be preferred. The largest imperial brass coin was the sestertius, and from the Augustan age went by the name of nummus, or æreus. It was worth twopence English. All the large brass coins are of yellow metal; the middle brass, yellow and red; the small, mostly red. No sensible dimunition of the sestertius took place till the reign of Alexander Severus, when it lost upwards of a sixth of its weight, and continued to diminish till the reign of Gallienus, when it totally vanished. In this reign the chief copper coins in use were the small brass, or asaria, which, according to the writers of the Lower Empire, were at last numbered at sixty to the silver denarius. Under Valerian and Gallienus, copper washed with silver appeared. In the reign of Diocletian, a coin denominated the follis supplied the place of the sestertius; but the denarii ærei continued quite common down to Constantine I. He introduced a new coinage, and then the follis had its changes and its subdivisions; but its appellation adhered to what had now become the largest brass coin of the Roman empire, to the very latest notices which we have of the Byzantine money. From the time of Augustus to that of Gallienus, the imperial or silver denarius contained sixteen asaria. Under Caracalla a larger denarius was struck, which had a half more or twenty-four asaria, and was called argenteus: the common denarius of silver being then termed minutus. Under Gallienus, however, the minutus ceased, and the argentius and denarius then became only different names for the Roman silver coin, which at that time contained no less than sixty asaria. Constantine I. introduced the milliarensis, worth somewhere about a shilling of our money: but the argentei, or denarii, were struck as late as the reign of Heraclius. Aurei and semi-aurei were the sole pieces in gold for near three centuries. Till Sulla's time the aureus continued at thirty silver denarii. In the reign of Claudius, and afterwards, it went for twenty-five silver denarii. Under Philip, aurei of two or three sizes first appear, of a rude fabric; one class of which were called trientes. The weight originally given to the aureus was 120 grains; it afterwards fluctuated to between 80 and 90 grains, and was sometimes even of less weight. Constantine I. accommodated the aureus to his new coinage, and gave it the name of solidus, of six in the ounce of gold. The solidus passed for fourteen milliarenses. It went for rather more than twelve shillings of our money, and continued of the same standard to the very close of the Byzantine empire. The medallions were struck both at Rome and in the provinces, whence the division of this class into Roman and Grecian. The term is applied to all those productions of the Roman mint which exceeded the coins ordinarily current in size, whether in gold, silver, or brass. Medallions, says Pinkerton, from the time of Julius to that of Hadrian are very uncommmon and of vast price: from Hadrian to the close of the Western Empire they are less rare. The types of the Roman medallions are often repeated upon common coin. Those struck in the Grecian territories are the most numerous, and are distinguished from the Roman by their thinness and inferiority of workmanship. Many Roman medallions have S. C. upon them, as being struck by the senate; other have not, as being struck by order of the emperor. The Roman medals called Contorniati, it is the opinion of our first medallists, were no more than tickets of admission for different places at the public games.

The third class of ancient coins, denominated *Barbarian*, consists of those of Lydia, Persia, Judæa, Phœnicia, Numidia and Mauritania, Carthage, Spain, Gaul, and Britain. The coins of Lydia and Persia have been already slightly noticed. The Darics, from their present extreme scarcity, are supposed to have been melted down for his own coinage by Alexander the Great, upon his conquest of Persia. Pinkerton asserts that all the real Darics were of gold, and that the silver coins with the archer (the same type) are later. Nevertheless many of the silver Darics are equally if not more archaic in appearance. Of Persian coins there is a second series, that of the Sassanidæ, beginning about A.D. 210, when Artaxerxes overturned the Parthian monarchy; they extend to the year 636, when Persia was conquered by the Arabian caliphs. The Hebrew coins were struck under the dominion of the family of the Maccabees, and chiefly in the time of Simon the high-priest, about the year 150 B.C. They are nearly all of copper, and extremely rude in workmanship; the legends are in Samaritan characters, and the symbols are those appropriate to the nation, such as a sprig, considered as Aaron's rod, sacramental cups, censers, &c. The Hebrew shekel, as it is called, is of silver, about the value of the Greek tetradrachm [SHEKEL]; and there were half and quarter shekels. Hebrew coins pretending to an earlier date than the Maccabees are spurious. The Phœnician coins are in no instance considered older than the time of Alexander the Great, and are chiefly referred to the cities of Tyre and Sidon. The Numidian coins are those of Juba I. and II. The Punic and Carthaginian coins are believed to have been struck by Greek artists. Those of Spain agree in character with the coins of the different nations by whom the several colonies of that country were planted, Phœnicians, Greeks, and Carthaginians; and many of them are inscribed with Phœnician, Greek, and Roman legends; a few others are met with, distinguished by what are called Celtiberian characters, not unlike the letters of the Runic and Etruscan alphabets. Of the coins of Gaul, the most ancient have no legends at all; they have very rude devices, and many of them are in base gold; after the Gauls had intercourse with the Romans, some of their coins bear inscriptions which look like Latin, mostly in single words, and not of easy interpretation; they are not unlike many of those which are called early British. Cæsar describes the Britons as a people just emerging from barbarism, and no further acquainted with commerce than to have discovered that it could not be conducted by simple barter alone. His account implies, that however they might have known its use, the Britons had not proceeded so far as actually to coin money; although they had a substitute for it in pieces of brass, or iron rings, or plates regulated by weight. He says, "Utuntur aut ære, aut annulis ferreis, ad certum pondus examinatis, pro nummo." ('Bell. Gall.' v. 12.) The passage, however is corrupt; for *annulis* some manuscripts read *taleis*, and others *laminis*. Coins however are found in this country which are usually attributed to the very early British kings, in gold, silver, and the inferior metals; ruder in fabric than they would have been had the Britons learned the art of coining them from the Romans. They are without legends, and many of them, like the early Gaulish coins already mentioned, have unintelligible devices; they seem to justify our antiquaries in thinking that Cæsar had not sufficient information to make his testimony quite conclusive. The use of a better sort of money was unquestionably taught the Britons by the Romans very soon after Cæsar's second invasion, when the types improved, and when no one who examines them carefully will doubt that Roman artists were employed upon the dies. The earliest coin which can, with the least appearance of probability, be attributed to any particular British monarch, bears upon it the letters SEGO, possibly for Segonax, one of the four Kentish monarchs who attacked Cæsar's camp at the time of the invasion we have just mentioned; it has also the word TASCIO upon it, which is seen upon numerous other coins which are undeniably British. Cunobelin was a later monarch of Britain, whose name is considered to be abbreviated upon the coins which have CVN, CVNO, and CVNOBELI upon them, together with the words CAMV and CAMVL, the leading letters of Camulodunum, his capital city, supposed to be either Colchester or Maldon in Essex. VER, as well as VERLAMIO at length, for Verulam, occur upon other coins of the same period. One has BODVO, which may or may not be a coin of Bonduca or Boadicea, queen of the Iceni. It is probable that the British coinage closed with the money of Cunobelin; for in a very few years after his decease the second subjection of Britain took place under Claudius, and was so complete and severe, that the country became rather a Roman than a British island. Gildas ('De Excidio Britanniæ,' c. v.) expressly speaks of a Roman edict which ordained that from that time all money current among the Britons should bear the imperial stamp. That this prohibition was followed up by the establishment of Roman mints in Britain is highly probable; and certain initial letters, as P. LON. for *pecunia Londini*, &c., are brought forward as evidence of the fact; but most of these initials are equally



Copper Shekel of Simon.

Shekel of Silver.



Coin of Cunobelin.

applicable to other places in the Roman empire where mints were established, and therefore do not afford a proof quite so conclusive as is wanted. We give a representation of one found in London. The coins of Carausius and Allectus, the seat of whose empire was in Britain, have a strong claim to be considered as the production of British mints. Those who wish to see under one view the 'Coins of the Romans relating to Britain,' will find the fullest information in a little volume published under that title by Mr. John Yonge Akerman, 12mo., London, 1844; much information will also be found respecting the Roman coins found in various parts of London, in Mr. Roach Smith's 'Illustrations of Roman London,' 4to, 1859.

Coin, with seated figure of Britannia.

Modern Coins are those which have been struck since the fall of the Western Empire; but it is impossible, in the space to which the present article is necessarily confined, to enter into minute details respecting the series of coins in each country. We shall be brief in our notices of the greater part, that we may devote a larger space to the coins of England.

The series of the coins of Italy under the Ostrogoths began soon after the year 480 of the Christian era. The French series commences with Clovis, A.D. 490. That of Spain with Liuva, Prince of the Visigoths, soon after the middle of the 6th century, or about A.D. 567. The states of Germany appear to have struck money very shortly after the age of Charlemagne; as well as the independent Lombard cities, and the Neapolitans. The Papal series of money begins with Pope Hadrian I., A.D. 772. Denmark has coins of an early date, but few of them are intelligible before the time of Canute; contemporary with whose date are the coins of the petty kings of Ireland. In Sweden coinage is said to have begun under Biorno, A.D. 818; and in Norway with Olave or Olaf, A.D. 1066. The Russian coinage is of a later date than the other coinages of Europe. Of Scotland pennies exist ascribed to Alexander I., A.D. 1107: those of William the Lion, A.D. 1165, are numerous. Pennies were the earliest coins in most of the European kingdoms, and a prevailing device upon them was a cross.

The *Coins of England* form the most complete modern series extant. At what time the circulation of the Roman money ceased, we are ignorant: but Sceattæ (from the Anglo-Saxon ꞅceaꞇ, shot, money) are known of the early kings of Kent, some of which must have been struck within the 6th century; and there are others so similar to them in type as to justify their appropriation to the same people, but which from their symbols were evidently coined before their conversion to Christianity. They are too rude generally to admit of description, are of silver, and found of different weights, from seven grains and a half troy to twenty and upwards: their most common weight is from fifteen to nineteen grains. Several plates of these coins are engraved in Ruding; they appear to have been current chiefly from the year 500 to 700. A sceatta of Ethelbert I. of Kent is the earliest Saxon coin which can be appropriated: he reigned from A.D. 561 to 616. Sceattæ also are the only coins which have hitherto been discovered of Egbert, king of Kent, who reigned from 665 to 674. In point of antiquity the penny succeeds; the name of which first appears in the laws of Ina, king of the West Saxons, who began his reign in 688. The word has had numerous etymologies; but that from *pendo*, to weigh, seems the most reasonable: it was then, as it still is, the 240th part of the nummary pound. The half of the penny, called helꝼlinꝫe or halꝼþeniꝫe, and the fourth part or ꝼeoꞃðunꝫ, farthing, are mentioned in the Saxon gospels; and a Saxon halfpenny of Edward the Elder is said to exist in the Bodleian collection at Oxford: but we know little more of the earliest divisions of the penny. The coin ascribed as a penny to Ethelbert II. king of Kent, between 749 and 760, with Romulus and Remus on the reverse, is beyond doubt a forgery. As to the rest of the kingdoms of the Heptarchy, no coins have yet been discovered of the South Saxon monarchs. Of the West Saxon kings, we have coins of Athelheard, A.D. 726; and of Beorhtric, who came to the throne in 784. Mercia seems to have been the most wealthy kingdom, and has a large series. It begins with Eadvald, who ascended the throne in 716, followed by Offa (whose queen Cenethreth or Quindred also enjoyed the privilege of coining), Egbert, Coenvulf, Ciolvulf I., Beornwulf, Ludican, Wiglaf, Berhtulf, Burgred, and Ciolvulf II., with whose short reign the kingdom expired. The coins of the East Angles begin with Beonna, about the year 690; but in consequence of the temporary annexation of the kingdom to that of Mercia, we have but few coins of succeeding monarchs: those only of Æthelweard, 760, Edmund the Martyr, 855, and Ethelstan, 860, are known. The kingdom of Northumberland has this remarkable peculiarity belonging to its coinage, that from its mints issued, as far as is yet discovered, the only brass coins which were struck by the Anglo-Saxons. The earliest specimen hitherto known is of the reign of Egfrith, who ascended the throne in 670: it differs from the stycas of succeeding monarchs in the omission of the moneyer's name on the reverse. Of sixteen succeeding monarchs (whose reigns occupy more than a hundred and thirty years), no coins have as yet occurred. The first that appears was struck by Eanred, who began to reign in the year 808. One silver penny of Eanred is known. His stycas are of various rude types, without any representation of the monarch, but with a legend similar to that on his silver coin, excepting that the moneyer's name stands on the reverse, without any addition. Other stycas occur of Ethelred his son 840, of Redulf, and of Osbert, whose reign began in 849. After his reign stycas seem to have fallen into disuse, at least none of a later period have yet been found. Stycas were also struck in the Saxon times by the archbishops of York: Ruding has engraved those of the archbishops Eanbald II., Vigmund, and Wulphere. One coin of Regnald, who was expelled the kingdom of Northumberland in 944, is known; and one of Anlaf, which has upon its reverse the Danish raven: these are pennies. Pennies also are known of Eric. At the beginning of the 9th century, Ecgbeorht or Egbert ascended the throne of the West Saxon kingdom; and in the course of his long reign brought under his dominion nearly the whole of the Heptarchic states; he is therefore commonly considered as the first sole monarch of England, notwithstanding those states were not completely united in one sovereignty until the reign of Edgar. On his coins he is usually styled ECGBEORHT REX, and sometimes the word SAXONVM is added in a monogram within the inner circle of the obverse: some of his coins have a rude representation of his head, and some are without it. From Egbert's time, with very few exceptions, the series of English pennies is complete; indeed for many hundred years the penny was the chief coin in circulation. Of the Saxon pennies those of Alfred bear a considerable price; on some he is called AELBRED REX, on others ÆLFRED. Edward the Elder has Saxon buildings on the reverses of several of his coins; and on one of Athelstan's is a building intended for York Cathedral. The coins of Canute and of Edward the Confessor are among the most common of the Saxon series; those of Hardicnut are rare. English coins of Canute have frequently, and of Hardicnut in a few instances, been found in Denmark. Numerous coins of Canute and Ethelred II. have also been found in Ireland.

Coin of Egbert.

The Archbishops of Canterbury, during a part of the Anglo-Saxon period, also coined money. Pennies exist of Jaenberht, Archbishop of Canterbury from 763 to 790; of Æthilheard, who died in 803; of Vulfred, who succeeded in that year; of Ceolnoth, who died in 870; of Ethered, 871; and of Plegmund, who sat from 891 to 923. In Athelstan's laws two moneyers are allowed to the Archbishop of Canterbury, but no archiepiscopal coins of that reign are known, nor indeed any until the time of Archbishop Bourchier, a space of several hundred years. Of Harold II.'s pennies there are three distinct types; two with the head looking to the left, the third, which is of very uncommon occurrence, with the head to the right; all have the word PAX in the centre of the reverse. Of the coins of William I. and II. the best account, with engravings of all the types, will be found in the 'Archæologia,' vol. xxvi. p. 1—25. Of the types there exhibited, those which bear the strongest resemblance to the coins of the Confessor and Harold are ascribed with great probability to the first William; those which most resemble Henry I.'s coins to William II. The coins which present a sceptre on each side of the king's head are universally ascribed to the Conqueror; those with two stars to William Rufus, the same ornament occurring upon his great seal. Most of them read PILLEM, PILEMV, or PILLEMVS REX A, AN, ANGLO, or ANGLOR; the P in Pillem being in reality the Saxon V (W). Of Henry I.'s pennies the types are as various as upon those of any monarch of the English series: the reverses bear the name of the mint and moneyer. This had been the Saxon practice, and it continued till the reign of Edward I. Our historians say that Henry I. coined halfpence and farthings, but none such are known in our cabinets. Through the Norman times, and certainly in the reign of Edward the Confessor, halves and quarters of the penny, regularly and nicely cut, to go as halfpence and farthings, occur almost whenever parcels of the coins of those periods are discovered. The troubles of Stephen's reign will account for the wretched state in which the pennies of that king occur: these, with what are certainly the earliest pennies of Henry II., are among the worst of the English coins in point of mintage. The barons of this reign are reputed by our historians to have struck coins; but only two or three such are known, and those of persons related to the king. Pennies are extant ascribed to Robert earl of Gloucester, bastard son of Henry I.; to Henry bishop of Winchester, base brother of Stephen; and to Eustace, Stephen's son. They are all of great rarity, as is the coin which bears the full-length effigies of Stephen and Henry II. The coin of Robert, however, is by some ascribed to Robert duke of Normandy, the eldest son of the Conqueror. Henry II., according to Ruding, had but one type; but there seems every reason to believe that the pennies which usually go by the name of the first coinage of King Henry III. are in reality the last coinage of Henry II. at the time he reformed his money, A.D. 1180. Of Richard I. and John we have no English money; but pence, halfpence, and farthings are extant of John, all struck in Ireland. Those coins with a full face, bounded by the inner circle, have the inscription IOHANNES DOM., and were struck at the time his father made him lord of Ireland; those which give the face inclosed in a triangle, and IOHANNES REX, were coined after he ascended the throne. The farthing of this last coinage is extremely rare. Of John's coins, Dublin appears to have been the only place of mintage. Henry III.'s pennies, (if those which we have considered as the latest pennies of Henry II. really do not belong to Henry III.) have usually the numerals added to his name, HENRICVS REX III. Some of his pennies have HENRICVS REX TERCI, and a few HENRICVS REX ANG. His coinage, if we may judge from the quantity of his pennies which still remain, must have been a very extensive one. Halfpence and farthings are spoken of in a record of this reign, but none have appeared. The pennies of Edward I. II. and III. are usually thus distinguished by our antiquaries: those which give the king's name EDW. are ascribed to Edward I.; those with EDWA., EDWAR., and EDWARD, to Edward II.; those with EDWARDVS, to King Edward III. A few with EDW. are known certainly to belong to Edward I., particularly those which have a moneyer's name on the reverse, ROBERT DE HADELEIE, who is known from records to have been a moneyer in 1280. Both Henry III. and Edward I. struck pennies in Ireland, in the manner of John's later coins, representing the king's head within a triangle. Edward I. struck halfpence and farthings in his great coinage of 1279, which are not unfrequently met with in the cabinets of collectors, as well as halfpence and farthings with the Irish type, struck at Dublin and Waterford. It may be sufficient, as regards these small coins, to say that they continued in currency for several centuries. The last silver farthing is known to have been coined in the reign of Edward VI., but no specimen of it has been seen: the last silver halfpenny was struck under the Commonwealth. The penny has continued through every reign to the present. Our limits will not allow of further minute description. Among the rarest in the later part of the series may be reckoned the pennies of Edward VI., Mary, and Philip and Mary. From the reign of Edward I. to Henry VIII., we have pennies which bear the privy marks of the Bishops of Durham; from Henry IV. to Henry VIII., we have coins struck in the archiepiscopal mint at York; and others of the see of Canterbury, from Archbishop Bourchier to Archbishop Cranmer. The first English pennies were 22½ grains troy. Towards the close of Edward III. the penny weighs 18 grains, and in the reign of Edward IV. it fell to 12, after previously sinking to 15. In Edward VI.'s time, 1551, the penny was reduced to 8 grains, and after the 43rd of Eliz. to $7\frac{23}{31}$ grains, at which weight it still continues. The penny affords the best rule for estimating the other silver coins.

According to Grafton, Henry III., in 1249, ordered groats to be stamped, but none such are mentioned in any record. There is a large piece however found occasionally in the cabinets of the curious, sometimes ascribed to Edward I., but whether his, or Edward II.'s, or Edward III.'s, is uncertain. It occurs of different weights, from 80 to 138 grains, and represents the king's head on its obverse, within a double tressure of four arches, with mullets and roses; inscribed EDWARDVS DI. GR. REX. ANGL. The reverse, besides a continuation of the king's titles in the outer circle, has CIVI. LONDONIA within an inner one. There can be little doubt that it was a trial-piece. Groats and half-groats were not introduced for currency till the 25th Edward III., and continue at present, though not for circulation. A silver fourpenny piece for circulation, of a different type from the ordinary groat, was issued for circulation by William IV., in 1836. The groat received its name from the French *gros*, a large piece. In the time of Henry VII. and Henry VIII. groats and half-groats were struck in the archiepiscopal mints of Canterbury and York. It was one of the charges against Wolsey, that he had put the cardinal's hat upon the king's money, as is seen upon his York groats and half-groats.

The testoon, or shilling, was first coined by Henry VII., in 1503. The appellation of testoon was from the *teste* or *tête*, the head of the king, upon it: that of shilling is of old but uncertain origin. Pinkerton says, that coins of that name had been struck at Hamburg in 1407. The ꞅcilling was a denomination of money in the Saxon times.

Henry VIII. struck some patterns for a silver crown; but the first crown for currency was struck by Edward VI., with the half-crown, sixpence, and threepence. Queen Elizabeth, in 1558, coined three-halfpenny, and in 1561 three-farthing pieces. Pinkerton says they were dropped in 1582, but there is a three-halfpenny piece in the cabinets of the British Museum, bearing the date of 1599. Charles I. struck twenty-shilling and ten-shilling pieces in silver, but they were of very limited currency.

From the 43rd Elizabeth, 1601, the denominations, weight, and fineness of English silver have remained the same, with the exception of the florin of two shillings and the fourpenny piece. It is worthy of remark, that, during all his distresses, Charles I. never debased his coin.

The gold coinage of England is next to the silver in point of antiquity. The gold current with us, till the 41st Henry III., was foreign. In that year, 1257, a manuscript chronicle, in the archives of the city of London, states that the king made a penny of the finest gold, which weighed two sterlings, and willed that it should be current for twentypence. Three specimens of it only are yet known to have reached us; and two out of the three are preserved in the British Museum. They are from different dies. This coin is engraved in Snelling's 'View of the Gold Coin,' in the last edition of Folkes's 'Tables,' and in Pinkerton's 'Essay on Medals.' It is from Edward III. that the series of English gold coin really commences, for no more occurs till 1344, when that prince struck florins. The half and quarter-florin were struck at the same time. The florin was then to go for six shillings, though now it would be intrinsically worth nineteen. This coin being inconvenient, as forming no aliquot part of larger ideal denominations, seems to have been withdrawn. None have yet been found, but a few quarter-florins are preserved in cabinets, and one half-florin is known. In consequence, in the same year, the noble was published, of 6*s.* 8*d.* value, forming half a mark, then the most general ideal form of money. The obverse represents the king standing in a vessel, asserting the dominion of the sea. The noble was also attended by its half and quarter. This coin, sometimes called the rose noble, together with its divisions, continued the only gold coin, till the angels of Edward IV., 1465, stamped with the angel Michael and the dragon, and the angelets or half-angels, were substituted in their place. Henry V. is said to have diminished the noble, still making it go for its former value. Henry VI. restored it to its size, and caused it to pass for 10*s.*, under the new name of ryal. The ryal of 10*s.* and the angel of 6*s.* 8*d.*, with their divisions of half and quarter, then continued the sole gold coins till, in 1485, Henry VII. issued the double ryal, or sovereign, of 20*s.*, accompanied by the double sovereign of 40*s.* Henry VIII., in 1527, added to the gold denominations the crown and half-crown, at their present value, and in the same year gave sovereigns of 22*s.* 6*d.*, ryals of 11*s.* 3*d.*, angels of 7*s.* 6*d.*, and nobles at their old value of 6*s.* 8*d.* In 1546 he struck sovereigns of the former value of 20*s.*, and half-sovereigns in proportion. Henry VIIIth's gold, like his silver coin, was in the latter part of his reign much debased. Edward VI. coined a treble sovereign; and under James I. the sovereign was called a unite. The former coins however continued, with a few variations, till Charles II. coined the guinea, so called from the Guinea gold, out of which it was first struck in 1663, when it was proclaimed to go for 20*s.*, but by tacit and universal consent never went for less than 21*s.* Charles II. likewise issued half-guineas, double guineas, and five-guinea pieces, which his successors, till George IV., continued. George I. and George III. issued quarter-guineas; and George III. pieces of seven shillings in 1797. In 1815 sovereigns and half-sovereigns, of 20*s.* and 10*s.* each, were again coined, and the guinea and half-guinea were gradually withdrawn from circulation.

With the exception of the styca, the copper coinage of England arose a thousand years later than its silver. Queen Elizabeth had a great aversion to copper money, although the necessities of her people for small change were obvious. She suffered a pattern to be struck as the PLEDGE. OF. A. HALF PENNY, and James I. and Charles I. actually issued farthing tokens also as pledges; but no authorised coinage of copper was struck till 1672, when halfpence and farthings of that metal were first made public money. In 1684 tin farthings were coined, with a stud of copper in the centre. Others, as well as halfpence of the same metal, were struck by James II., and William and Mary. In 1693 the tin was called in, and copper renewed. Pieces of a penny and twopence in copper were coined in the reign of George III. The latter did not answer their purpose, and were soon discontinued. In 1852, half-farthings were coined, chiefly for use in the colonies; and in the parliamentary session of 1859, the chancellor of the exchequer announced the intention to change the copper coinage for one of a mixed and harder metal, of which the weight of each coin would be about half its present weight. Neither the denominations nor the value were to be changed.

Our space will allow us to say less than we could wish upon the money struck in France by English princes. Of Anglo-Gallic silver coins we have deniers of Eleanor, wife of Henry II., as duchess of Aquitaine, with deniers and half-deniers of Henry II., and pennies and half-pennies of Aquitaine, and pence of Poitou and Rouen of Richard I. Of John and Henry III. we know of no Anglo-French money; but there is a lion of billon of Edward I., coined during the lifetime of his father after he had received Gascony, and a plentiful series of silver and billon coins of Edward III., of Edward the Black Prince, of Richard II., Henry IV., V., and VI. The denominations of the silver were the hardi, double hardi, groat, half-groat, penny, and half-penny. In this class also fall the Calais groats and half-groats of the sovereigns of England, from Edward III. to Henry VI., and the Tournay groats of Henry VIII. Edward III. was the first of the English princes who struck gold money in France; the denominations were guiennois, leopard, chaise, and mouton; to these Edward the Black Prince added the hardi of gold and the pavilion; and Henry V. salutes and half-salutes. Henry VI. coined salutes, angelots, and francs in gold. The equivocal specimen of silver coin, supposed to have been struck by Margaret of Burgundy for Perkin Warbeck, is usually classed with the Anglo-Gallic series. The British Museum possesses a most extensive and interesting collection of coins, those of Great Britain being the largest collection in existence, and the collections of Sicilian, Greek, and Roman coins exceedingly rich.

Gold and silver with certain alloys have formed the material for the more costly currency of all European nations, and copper for most of them in those of smaller value, but France and some few others have used a mixed metal for that purpose. Russia is the only country which has used platinum in the manufacture of coins.

In respect to numismatic writers, we can only enumerate a few of the most important upon the various series of coins. On the Greek and Roman series, the best works are Eckhel's 'Doctrina Numorum Veterum,' Rasche's 'Lexicon Universæ Rei Numariæ,' and Mionnet's 'Description des Medailles Antiques Grecques et Romaines;' the last work in 5 vols., 8vo, with 7 vols. of Supplement, Paris, 1806–35. For the Roman alone, the reader may consult A. Morel's 'Thesaurus Familiarum Romanarum,' 2 tom., fol., Amsterdam, 1734; and his 'Thesaurus Numismatum Imperatorum,' 3 tom., Amsterdam, 1752. Another, which brings the Roman series to the close of the empire, will be found in Banduri's 'Numismata Imperatorum Romanorum a Trajano Decio ad Palæologos Augustos,' 2 tom., Par., 1718, with Tanini's 'Supplement,' in 1 vol., fol., Rome, 1791. See also Mionnet's work, in 2 vols., 'De la Rareté et du Prix des Medailles Romaines,' 8vo., Paris, 1827; Mullinger's 'Considerations sur la Numismatiques de l'ancienne Italie,' 1844; and Akermann's 'Descriptive Catalogue of Rare and Unedited Roman Coins,' 2 vols., 8vo, London, 1834. Pinkerton's 'Essay on Medals,' 2 vols., 8vo, 1789, with all its errors, is valuable as a general elementary treatise. A better is Mayer's 'Einleitung in die älte Römische Numismatik,' 1842; and also Mr. B. N. Humphrey's 'History of Ancient Coins and Medals;' 'The Proceedings of the Numismatical Society,' of which the publication commenced in 1836, contain a large amount of valuable information.

On English coins, the best works are Leake's 'Historical Account of English money,' 8vo, London, 1745; Ruding's 'Annals of the Coinage of Britain;' and Mr. Humphrey's 'Coins of England,' and 'Coin Collector's Guide.' Simon has written an 'Essay towards an Historical Account of Irish Coins;' and Cardonnel his 'Numismata Scotiæ, or a Series of the Scottish Coinage.' On Anglo-Gallic coins, we have a quarto volume by Ducarel; a volume of similar size, 'A Description of the Anglo-Gallic Coins in the British Museum;' and 'Illustrations of the Anglo-French Coinage,' by Major-Gen. Ainslie, 4to, London, 1830.

On the French coinage, we have the works of Bouteroue, Le Clerc, and Millin; on the Papal coins, Floravante; Flores on those of Spain. For the coins of Germany the reader may consult Madai's 'Thaler-Cabinet,' 4 tom., Königsberg, 1765–8; Weise's 'Gulden-Cabinet,' 2 tom., Nürnberg, 1780–2; and Vossberg's 'Geschichte der Preussischen Münzen und Siegel,' 1843. For Danish coins, the 'Danske Mynter og Medailler,' 3 tom., fol., Copenh., 1791–4. For Bulgarian coins, Fraehn's work, 4to, Casan, 1816. For Hungarian coins, Schönvisner, 'Notitia Hungariæ rei numariæ,' 1801, and Szecheayi 'Catalogus numorum Hungariæ,' 1810. For Russian coins Chaudoir's 'Aperçu sur monnaies russes,' 1837. For Polish coins Bandske's 'Numismatyke Krajowa.' 1839. For Oriental coins, Marsden's 'Numismata Orientalia Illustrata,' 2 vols., 4to, London, 1823–5; Grotefend's 'Münzen der Griechischen, Parthischen, und Indo-Skythischen Könige von Bactrien;' and 'Essays on Indian Antiquities, Historic, Numismatic, and Palæographic,' by James Prinsep, edited by J. Thomas, 1858.

COINING. [MINT.]

COINING. The numerous and complicated laws upon this subject, passed from time to time during several centuries, as occasion called for penal enactments to protect the coin of the realm, were repealed by the stat. 2 Will. IV. c. 34. The making or coining of money being one of the exclusive prerogatives of the crown, the counterfeiting of the king's coin was in early periods of the history of English law considered to be an usurpation upon the royal authority, and upon that principle constituted the offence of high treason both by the common law and by various statutes. By the stat. 2 Will. IV., c. 34, s. 3, the following offences are provided for:—1. Falsely making or counterfeiting any coin resembling, or apparently intended to resemble or pass for, the king's current gold or silver coin. 2. Colouring, washing, or casing over any metal or counterfeit coin so as to pass for the genuine gold and silver coin of the realm; and filing, washing or otherwise altering silver coin so as to pass for gold, or copper coin so as to pass for silver or gold. 3. Impairing, diminishing, or lightening gold or silver coin, with intent to make it pass current. 4. To buy, sell, receive, pay or put off, any false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current gold or silver coin, or offer so to do, at or for a lower rate or value than the same by its denomination imports. 5. To import into the United Kingdom, from beyond the seas, any false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current gold or silver coin, knowing the same to be false or counterfeit. (The above offences were punishable by transportation, now penal servitude). 6. To tender, utter, or put off any false or counterfeit coin, resembling, or apparently intended to resemble or pass for, any of the king's current gold or silver coin, knowing the same to be false or counterfeit. 7. To tender, utter, or put off any false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current gold or silver coin, knowing the same to be false or counterfeit, and at the time of such tendering, uttering, or putting off, having in possession, besides the false or counterfeit coin so tendered, uttered, or put off, one or more piece or pieces of false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current gold or silver coin; or 8. Either on the day of such tendering, uttering, or putting off, or within the space of ten days then next ensuing, to tender, utter, or put off, any more or other false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current gold or silver coin, knowing the same to be false or counterfeit. 9. Any person having in his custody or possession three or more pieces of false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current gold or silver coin, knowing the same to be false or counterfeit, and with intent to utter or put off the same. (The four last offences are punishable by imprisonment.) The punishment is increased for the commission of any of these offences after a previous conviction.

The provisions above abstracted relate to the protection of the gold and silver coin. The following offences relate to copper coin. 1. To falsely make or counterfeit any coin resembling, or apparently intended to resemble or pass for, any of the king's current copper coin; or, 2. Knowingly, and without lawful authority (the proof of which authority lies on the party accused), to have in his custody or possession any instrument, tool, or engine adapted and intended for the counterfeiting any of the king's current copper coin; or, 3. To buy, sell, receive, pay, or put off, or offer to buy, sell, receive, pay, or put off, any false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current copper coin, at or for a lower rate or value than the same by its denomination imports. 4. To tender, utter, or put off any false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current copper coin, knowing the same to be false or counterfeit, or having in custody or possession three or more pieces of false or counterfeit coin resembling, or apparently intended to resemble or pass for, any of the king's current copper coin, knowing the same to be false or counterfeit, and with intent to utter or put off the same.

The statute also contains various provisions against making, sending, or having in possession, any coining tools. By the 16 & 17 Vict. c. 48, the provisions of the 2 Will. IV., c. 34, were extended to the colonies, and punishment provided for importing counterfeit coin into the colonies. A practice which arose of defacing coin by stamping and bending it for advertising purposes was met by the 16 & 17 Vict. c. 102, making the offence a misdemeanour, and imposing a penalty on uttering such defaced coin. The statute also makes a tender of such coin invalid.

COIRE. The manufacture of cordage, mats, matting, coarse canvas, and sailcloth from the fibres of vegetables, has been known to the inhabitants of nearly all countries with which we have any acquaintance. So far, however, from the source from which the material is obtained being alike in all plants, it differs considerably. In flax and hemp the fibrous material is furnished by the stem, deprived of its ligneous centre or core. In the Spanish broom the fibres are furnished by the young pliant branches of a shrub; and these fibres are occasionally wrought both into cloth and into cordage. The stalks of the hop-plant, and also of the common nettle, are made to yield fibres applicable to a similar purpose; and so likewise may be those of the bean-plant and of the mallow. In other cases it is rather the bark of a tree than the stem of a young plant that yields the fibres. Such is the case with the paper-mulberry tree, the bark of which is so prepared by the natives of Tahiti as to yield fibres fitted for a kind of cloth. Such is likewise the case with the linden-tree, the bark of which, prepared in a suitable way, is used for the manufacture of mats, baskets, bags, and thatching. It is estimated that fourteen million mats are made annually in Russia from this material; that for this purpose the bark of a million trees is required; and that a traffic equal to half a million sterling is thus created. Two other examples of the same kind are furnished by the maho-tree (*Hibiscus tiliaceus*) and the *Theobroma augusta*, two East Indian plants, the stalks of which are steeped and disentangled from the fibres of the inner bark. Another class of materials for similar purposes is furnished by the leaves of certain plants. The *Phormium tenax*, or New Zealand flax, has leaves which produce such fibres. The enormous leaves of the *Agave*, or American aloe, yield fibres capable of answering a similar purpose; and so likewise do several species of the *Bromelia*.

But *Coire* differs from all these in its origin. It is the fibre of the husk of the cocoa-nut, bearing such relation to it as the downy fibres of cotton do to the seeds of the cotton-plant. The inhabitants of Ceylon make great use of it. The nut is gathered before being completely ripe; and in order to remove the husk, an iron spike or sharp piece of hard wood is fixed in the ground, and the nut is forced upon the point in such a manner as to separate the rind from the shell. One man can clear about a thousand nuts in a day by this means. The rind of the nut is soaked in water for several months, then beaten upon a stone with a piece of heavy wood, and afterwards rubbed with the hand until the intermediate substance is completely separated from the fibrous portion. The rind of forty average nuts supplies about six pounds weight of the fibre. This fibre constitutes the coire, which is then ready for use in the same way as hemp or other fibrous materials.

This material possesses great tenacity. Indeed, Dr. Roxburgh remarks, that "coire is certainly the very best material yet known for cables, on account of its great elasticity and strength." The material is very buoyant, and well suited for making ropes of large diameter. Until chain-cables were introduced, all the ships which navigated the Indian seas had cables made of this substance. The fibres are rather improved than injured by immersion in sea-water; but the smoothness and elasticity of the coire-cordage, though very advantageous to running-rigging and the light lines of a ship, render it less fitted for standing-rigging.

There has been a branch of manufacture introduced within the last few years in England, in which coire is employed rather differently than in the above-described instances; this is for the production of rugs, druggets, mats, matting, mattresses, and similar coarse goods. Dampier mentioned two or three centuries ago the production of cloth from such a material; for he says, "I have been told by Captain Knox, who wrote the 'Relation of Ceylon,' that in some places of India they make a sort of coarse cloth of this husk of the cocoa-nut, which is used for sails. Myself have seen coarse sailcloth made of such a kind of substance." Besides the actual weaving or plaiting of this material into textile fabrics of a coarse kind it is used as a stuffing for mattresses, pillows, and cushions. Dampier alluded to the use of the fibres to caulk the seams of ships; and Mr. Marshall speaks of the employment of them in India in stuffing mattresses, cushions for couches, and saddles, as a substitute for horse-hair. The availability of the material for such a purpose seems to depend upon these qualities: that the coire is very indestructible; that it does not harbour vermin, as horse-hair would in a warm climate; and that it is free from offensive smell.

The quantity of coire now imported is large, but it cannot be quite determined from the Board of Trade returns, in which it is included with "jute, and other vegetable substances of the nature of hemp."

COKE, the solid residue obtained by the destructive distillation of coal. It consists almost entirely of carbon, associated with a certain quantity, usually small, of incombustible mineral matter, which is left behind as ash when the coke is burnt.

As an article of commerce, it is produced by partial combustion in close chambers, or in heaps from which the free access of air is excluded. Being composed almost entirely of carbonaceous matter, coke is a fuel much purer and better adapted for use in smelting and various other furnaces than raw or uncoked coal; and as it is divested of those constituent parts which produce most dark-coloured smoke, it is especially preferred in cases in which it is necessary to avoid the emission of smoke, as for the furnaces of locomotive engines. The introduction of railways has occasioned a very large demand for coke for this purpose, though its use in the manufacture of iron has been diminished in some degree by the adoption of the hot-blast for furnaces, by the aid of which uncoked coal may be used in lieu of coke.

The simplest mode of coking, which is still occasionally followed, is to lay the coal in large flattened heaps, often containing 30 or 40 tons each, in the open air, covering it with ashes and earth to confine the heat, so that the mass of coal may be slowly burnt in a smothered manner, men being employed during the process to renew the covering wherever the fire may begin to burn through too fiercely. The late Dr. Ure, in describing various modes of making coke in Germany, noticed both circular and oblong coking *meilers* or mounds of this character, the former being piled round a central chimney built of loose bricks, towards which small horizontal flues are laid among the lumps of coal forming the mound; while in the latter vertical flues or chimneys are provided by the insertion, while the mounds are forming, of wooden stakes, which, when the whole pile is completed, are withdrawn, their place being filled up with readily combustible materials, to aid in igniting the mass of coal. The exterior of these meilers is covered with *slack*, or coal-dust, and clay.

The best and most economical method of making coke is in close ovens, which are built in various forms. In some large establishments these ovens are a hundred or more in number, each being a brick structure eight or ten feet high, with a flat roof in which is an opening for introducing the coal, and with another opening in front from which to remove the coke. The ovens being placed side by side in a continuous range, a railway is laid along their flat roofs by which the coal is brought close to the charging-holes, while another, running on a lower level, in front of the openings by which the coke is taken out, affords facilities for its removal. Dr. Ure gave details of various forms of coke-ovens, of which we can only notice the very excellent kind adopted by the London and North-Western (at that time the London and Birmingham) Railway Company for making coke at the Camden Town station, for the use of their locomotive engines. Each of these ovens was, internally, of an elliptic form, measuring 12 feet by 11 in the clear, and surrounded by brick-work 3 feet thick. The internal height was about 4 feet, the floor being flat, bedded upon a thick stratum of concrete, and the roof in the form of a flat dome. In the front of each oven was an opening about 3 feet square, covered by a cast iron door lined with fire-bricks, which slid up and down by means of chains and counter-weights. At the back of the roof was an opening, capable of being wholly or partially closed by a sliding damper communicating with a horizontal flue which conducted the smoke to a high chimney serving for the whole range of ovens. The ovens were charged through the front opening with about three tons and a half of coals, upon the top of which a little straw was thrown. The oven being very hot from its preceding charge, smoke began immediately to rise from the mass, while the straw became ignited by radiation from the dome. By the active combustion thus excited on the surface of the coal the greater part of the smoke was consumed, all that arose from the half ignited coals having to rise through the fully-kindled coals on the surface, which were freely exposed to the access of air, both the furnace door and the flue being for a time left fully open. As the operation proceeded, the fire burned regularly downwards, and the doors and dampers were gradually closed. After a calcination of upwards of forty hours the doors and dampers were perfectly closed, by which means the mass was partially cooled, and formed itself into prismatic concretions, somewhat resembling columnar basalt; when sufficiently cooled the furnace was opened, and the mass of coke broken up with iron bars and thrown out upon the pavement to be extinguished by sprinkling water over it. When the coking is conducted in this manner a very small quantity of unconsumed gas and soot escapes, and the coals, if good, yield about 80 per cent. of compact glistening coke, weighing about 14 cwt. per chaldron. The more recent operations of the railway companies have led to the introduction of many improved processes in coke-making. In ordinary coking-ovens the loss in weight is about 25, instead of 20 per cent., but the bulk of the coal is increased about 25 per cent. by the process.

The production of coke in the manufacture of coal-gas is noticed under GAS-LIGHTING.

In 1854 the London and North Western Railway company requested Messrs. Woods and Marshall to institute a series of experiments, to determine whether coal could advantageously be used in substitution of, or in combination with, coke in locomotive engines. The experiments were made with Hawksbury coal, dug from a pit near Coventry; it was selected on account of the proximity of the pit to the railway, and also because the coal is hard, and possessed of other favourable qualities. The main coal could be supplied in large lumps at the Rugby depôt for 9*s.* 8*d.* per ton. Some of Mr. M'Connell's locomotives were tried, alternately with Hawksbury main coal and with the best coke. Under nearly equal circumstances in other respects, a consumption of 25 lbs. of coke was found to equal that of 35 lbs. of coal, in working effect; and 8½ lbs. of water were evaporated by 1 lb. of coke, against 5¾ lb. by 1 lb. of coal. In trials with various engines, drawing various loads, the comparative results were nearly as above, in some cases more favourable to the coke. The result of the experiments showed that the use of coal in locomotives is quite practicable; that the engines, with coal fuel, have no difficulty in maintaining the required speed and pressure of steam; that the consumption, or rather non-production, of smoke may be very nearly attained; but that the last-named advantage depends very much on the skill and attention of the men employed, there being a necessity for a much more frequent supply, and for smaller quantities at each firing. Taking the results of one particular locomotive as an example, it was found that 1 ton of coke did about as much work as 1½ tons of coal; but as the price of a ton of the latter was 9*s.* 8*d.*, and that of the other 21*s.*, the money-cost for a given amount of power produced was less in the coal to the extent of nearly 7*s.* per ton. The experimenters found, however, that the company possessed only a small number of one particular kind of engine suitable for burning coal without producing smoke; and it would become, therefore, a commercial question how far it would be worth while to build new engines for the sake of ensuring these advantages.

There has long been, and still is, a controversy among practical men, not only concerning the relative qualities of coke and coal for use in locomotives, but in furnaces generally. At Pellatt's glass-works, near Blackfriars' Bridge, coke has been found to possess better qualities than coal for heating the kilns: 13 cwt. of coke was found to produce as much heating effect as 20 cwt. of coal. It has been found that, if a little coal be mixed with a preponderant quantity of coke, the glass ingredients become refined many hours earlier, the effects are more certain, there is less injury to the melting-pots, there is much less emission of smoke, and there is less cost by 2½ per cent. than when coal alone is used. The best coke is found to be obtainable from Newcastle coal, the next best from Wigan, a third quality from Barn-ley, and a quality nearly as good as breeze from cannel coal. The sooner coke is used after making, especially if gas-coke, the better. It has been laid down by some manufacturers, that whenever a chaldron of coke is sold at a lower price than a ton of small coal, it is cheaper to use coke than coal. Many manufacturing establishments now mix coke largely with their coal, thereby greatly lessening the emission of smoke; but in the North, where coal is cheaper, and where smoke-prevention is little thought of, coke is not much used in steam-engine furnaces. Many persons object to the use of gas-coke, on account of the unpleasant smell of sulphur belonging to it; to remedy this, one of the gas companies at Liverpool is in the habit of using salt, in the ratio of 14 lbs. to every charge of coal; this is said to lessen considerably the sulphureous exhalation from the coke. From various and somewhat conflicting reports of experiments made, it would appear that the relative profitableness of coke and coal as fuel depends greatly on locality; the ratio between the prices of the two being by no means uniform. If, on the one hand, manufacturers are trying to substitute coke for coal in many fixed furnaces, railway companies, on the other, are seeking to substitute coal for coke in locomotives. The experiments require to be carried to a much greater extent, before these problems can be effectually solved.

Many patents have been obtained for peculiar methods of preparing coke; but they do not require any lengthened notice. One is for a mode of applying muriatic acid to small coal, to dissolve the carbonates of lime and magnesia, and other impurities, after which the roasting is effected. Muriatic acid being rather a costly liquid when thus employed, it is suggested to employ the refuse acid from alkali works. Another is for a mode of obtaining ammoniacal salts. The products of combustion are to be drawn off by a blower into a flue, in which is placed a refrigerator; they then pass into a condensing chamber, where they come in contact with surfaces over which a stream of dilute sulphuric acid is trickling; the ammonia is taken up, and the non-condensible gases allowed to pass off.

COLCHICINE, the active principle of the meadow saffron (*Colchicum autumnale*). It was at one time regarded as identical with veratrine. It is soluble in water, alcohol, and ether. It forms salts with the acids, which are bitter, acrid, and poisonous. In small doses it causes purging.

COLCHICUM, *Medical uses of.* In a small dose, colchicum causes an increased flow of urine, and more frequent evacuations from the intestinal canal, and occasionally augmented secretion from the skin; in larger doses, frequent evacuations from the intestines, accompanied with pain and tenesmus, and desire repeatedly to empty the bladder. Still larger doses cause increase of all these actions, with vomiting and sense of burning in the throat, insensibility and stiffness of the tongue, escape of blood into the intestinal canal, vomiting of blood, and a flow of bloody urine. Great disturbance of the nervous system is likewise observed, as in other cases of poisoning with acrid substances. The same appearances are found in the intestinal canal, if the poison be injected into the veins. Even the milk of cattle which have eaten the meadow-saffron becomes capable of causing death. (Vogt.)

In a moderate dose, colchicum seems to increase the quantity and improve the quality of all the secretions of the intestinal canal and the collatitious viscera, especially the liver; but it likewise exerts a sedative action on the heart. Chelius says that in twelve days it doubles the quantity of uric acid found in the urine, a circumstance which explains its utility in gout and rheumatism.

The diseases in which colchicum is most useful are, dropsy, when a small dose is prescribed; gout, in which larger are used; and rheumatism, in which its beneficial influence is first felt on the liver (which is almost always disordered in these diseases), and afterwards on the kidneys, from which a larger portion of uric acid is excreted, and the formation of gout-stones (urate of soda) in some degree prevented. As acid in the stomach renders the action of colchicum more violent, magnesia is usually given along with it. The acetate and acetous extract are the best forms of administration.

COLCOTHAR. [IRON, *Sesquioxide of.*]

COLD. [CATARRH; HEAT.]

COLE, COLZA, a cultivated state of the *Brassica napus*, which does not form a close head, like cabbage, but has sessile heart-shaped leaves. It is cultivated for its seeds, from which an oil is expressed, which is much used for burning in lamps, and in the manufacture of leather and soap.

There are two varieties of cole, one with white flowers and another with yellow; the latter is the hardiest, and consequently most generally cultivated.

It requires a good loamy soil, well manured, to produce a good crop of cole seed. In rich land lately broken up from pasture, or fenny land newly drained, it grows luxuriantly and gives a great return. It is thought to be a great exhauster of the soil. Half a gallon of seed is drilled in rows 14 or 16 inches apart about the end of July, and left thinned out until the following year, when it is cut in June and July, yielding 20 to 30 bushels of seed, which is sold at from 8*s.* to 10*s.* a bushel. An oil is expressed from it, and the refuse, a rape cake, is made as food for sheep or cattle; being worth for that purpose more than its comparatively low price, 6*l.* per ton, when oil cake is 10*l.* to 12*l.* a ton, would indicate. In a rotation, cole is considered as a good crop to precede wheat. Like rape, which is another variety, it is sometimes sown to be fed off by cattle and sheep on land which is not so well adapted to the growth of turnips. [RAPE.]

COLIC (from κῶλον, *colon*), *dolor colicus*, called by Sydenham and the old English writers the dry belly-ache; a disease attended with severe pain of the bowels, remitting and recurring at intervals, with constipation, and without fever. The seat of this malady is conceived to be chiefly, if not entirely, in that portion of the large intestines called the colon, and hence its name. It arises from a great variety of causes, and assumes a corresponding variety of forms, many of which have received distinct names; but pain and constipation of the bowels, with the absence of fever, are common to them all; and this concurrence of symptoms is essential to the medical notion of colic.

The pain in colic often most distinctly follows the course of the colon, while the morbid distension and contraction of the bowel (for these two morbid states alternate with each other, and attack successively different portions of the intestines) often become visible to the eye. The colon receives all that portion of the food which is not converted into chyle, together with all those portions of the pancreatic, biliary, and intestinal secretions, which do not form component parts of the chyle. Consequently it has a considerable mass of matter to carry downwards and convey out of the system. It is provided with muscular fibres, very much larger than those which belong to the small intestines. These fibres form three large bands, which are placed in a longitudinal direction along the intestine, and which produce the effect of dividing the inner surface of the colon into folds, so disposed as to form little distinct apartments called cells. In these cells the feculent matter, which should be slowly but progressively carried downwards, is sometimes collected and closely impacted, so that when at length rejected it has the form of those cells constituting hard rounded balls, termed *scybalæ*. The natural stimulus to the muscular fibres of the colon is the resinous portion of the bile [BILE, NAT. HIST. DIV.], together with the non-nutrient portion of the aliment. It is easy then to conceive how a loss or diminution of the contractile power of these fibres may occasion the constipation incident to colic, attended with the retention of the feculent matter in the cells of the colon; how a suppression or an altered condition of the bile may contribute to the same effect; and how an acrid quality of the bile and of the non-nutrient portion of the aliment may produce the irritation and pain incident to colic. The colon then, both from its structure and function, it is obvious must be peculiarly predisposed to such an affection as that to which, from the frequency with which it is the subject of the malady, it has given a name. It is perhaps desirable that the term colic should be restricted to the designation of a disease of a definite character, seated in the colon; and some medical writers do so limit the use of the term, though others give it a more extended signification, and with less propriety include under it diseases which do not arise primarily in the colon, but in some neighbouring organ, the colon being only secondarily and sympathetically affected.

Colic, properly so called, is attended with severe griping pains in the bowels, which often follow very accurately the course of the colon; sometimes having their seat in one portion of it and sometimes in another. These pains remit for a time, affording intervals of ease; but they soon return with increased violence. They are often relieved by pressure, a character by which they are distinguished from pain occasioned by inflammation, the latter being always increased by pressure. The pain is usually attended with a greater or less degree of flatulence. The flatus sometimes collects to such an extent as to occasion a prodigious dilation of the bowels, greatly increasing the pain. When the digestive process is perfectly natural, it is always attended with the evolution of some portion of gas; in disordered states of digestion, the quantity of gas is often very much increased. While one portion of the intestine is thus preternaturally distended, another portion is in a state of preternatural contraction, from the irregular spasmodic action of the muscular fibres of the colon, excited by the irritating cause—whatever it may be—which produces the disease. These irregular spasmodic contractions of the colon are always present when this disease is severe, and are intensely painful. The constipation, which is so constant as to be a diagnostic character of the malady, is often long continued and obstinate, and the consequent accumulation of feculent matter is very great. To the preceding train of symptoms is very frequently superadded vomiting, which is often urgent and most distressing; and in cases of the greatest severity, the action of the whole intestinal tube above the seat of the disease is inverted, and the fæces are mixed with the matter vomited. Occasionally there is hiccough, and very often the griping pains are attended with loud rumbling noises in the interior of the intestines.

It is unnecessary in this place to enter into the details of the varieties of this malady to which physicians have assigned distinct names, since these varieties are merely modifications of the same disease produced by different causes. The preceding account will be sufficient to give to the general reader a distinct conception of the nature of the malady, and of the causes which produce it; and it is only necessary to observe respecting the treatment, that the two great principles on which the cure depends are the complete evacuation of the intestines, and the strict regulation of the diet. It is indispensable that the evacuation of the intestine of its accumulated and irritating contents should be complete, and this is best effected by an alternation of mild and unirritating aperients, with opiates. After the intestine has been fully relieved of its load, it is necessary to persist in a course of mild aperients for a considerable time; because the bowel long remains in an irritable state, and very slight causes are apt to occasion a relapse. For the same reason only the most bland and unirritating substances should be taken as food; all acid and acrid matters in the solid and all stimulating matters in the fluid aliment should be most carefully avoided.

The accidental introduction of lead into the system often produces symptoms resembling those of ordinary colic. [PAINTER'S COLIC.]

COLISEUM, OR COLOSSEUM. [AMPHITHEATRE.]

COLLATERALS. [CONSANGUINITY.]

COLLATIO, or MOSAICARUM ET ROMANARUM LEGUM COLLATIO, or LEX DEI, is a compilation, probably made in the 6th century of our era. It consists of a comparison between the Law of Moses and the Roman Law, in sixteen titles. Each title has certain legal rules at the head from the Law of Moses, headed thus, "Moses dicit;" to which are subjoined, by way of comparison, rules of Roman law taken from the five Roman jurists—Papinian, Paulus, Gaius, Ulpian, and Modestinus—and from the three compilations which preceded that of Justinian—the Gregorianus Codex, Hermogenianus Codex, and Theodosianus Codex. The value of the Collatio consists solely in the extracts which it contains from the source above mentioned. The last and best edition of the Collatio is by Blume, in the Bonn edition of the 'Corpus Juris Ante-Justinianei,' and in the separate edition of 1833, 8vo. The first edition is by P. Pithou, Paris, 1573, 4to. It is also printed in Schulting's 'Jurisprudentia Vetus ante-Justinianea,' Leyden, 1717.

COLLATION. [BENEFICE.]

COLLE'GIUM, or CONLE'GIUM, from the word *colligo*, "to collect or bring together," literally signifies any association or body of men; but a technical meaning was attached to it, namely, that of a number of persons joined in some office or employment, or living by common rules. The word Corpus was also used in the same sense (D. 50, 6, 5), and those who were members of a collegium or corpus were hence called corporati. The word Universitas was sometimes used as equivalent to Collegium or Corpus, but it had also the more general signification of "community," or "collective body of citizens." In the Roman polity collegium signified any association of persons such as the law allowed, requiring confirmation by special enactment or by a senatus consultum, or an imperial constitution, in which case it was called Collegium Legitimum. A collegium necessarily consisted of three persons at least. (Dig. 50, tit. 16, l. 85.)

In general, any association or collegium, unless it had the sanction of a senatus consultum, or of the emperor, or were established by a lex, was illegal (illicitum); and on proof of such illegality, might be dissolved by imperial letters (mandatis), constitutions, and senatus consulta; and when dissolved, the members were allowed to divide the property of the association according to their respective shares. (D. 47, 22, 3 pr.) The members of a collegium were called sodales; the terms and object of their union or association might be any that were not illegal.

A great variety of collegia (many of them like our companies) existed at Rome and in the empire, as we see by ancient writings and inscriptions, such as the Collegia Fabrorum, Pistorum, Pontificum, Fratrum Arvalium, Virorum Epulonum, Augurum, &c. Some of these, such as the colleges of Pontifices and Augurs, were of a religious character. These collegia possessed property as a corporate body; and in the time of the Emperor Hadrian, if they were collegia legitima, they could take a legacy or bequest (C. 6, 24, 8) in their corporate capacity. Collegia were allowed, as a matter of course, to have a common chest, and an actor, syndicus or attorney, to look after their rights and interests, and appear on their behalf. Plutarch ascribes the origin of colleges, as a political institution, to Numa Pompilius; and Dionysius mentions an ancient law, passed by Tarquin the Proud, for the purpose of putting down the societies and colleges which were then in existence at Rome. That the institution was often perverted to improper ends, we have proof not only in the writings of the Roman authors (see, among others, Cicero, 'Pro Sextio,' c. 15), but in the repeated enactments that were aimed at the colleges from time to time. (See Suetonius, 'Julius Cæs.,' c. 42; and 'Augustus,' c. 32.) (D. 3, 4, 1, 1.) The maxims—that what was due to a university was not due to the individual members; and that the debts of universities were not the debts of the individual members; and that even though all the members were changed, the university still existed—comprehend the essential notion of a corporation as understood by the law of England.

In England, a COLLEGE is an eleemosynary lay corporation, of the same kind as an hospital, existing as a corporate body either by prescription or by the grant of the king. But as regards Christ's Church, Oxford, that has been held to be a spiritual body, as being, not a college, but a dean and chapter. (Fisher's case, Bunbury, 209; and in Pitt v. James, Hobart, 122.) Trinity College, Cambridge, was expressly held to be a spiritual corporation, under the Stat. 1 & 2 Phil. & Mary. A college is not necessarily a place of learning. An hospital, also, is not necessarily a mere charitable endowment, but is sometimes a place of learning, as Christ's Hospital, London. Its particular form and constitution depend on the terms of the foundation. (Phillips v. Bury, 1 Lord Raymond 5; and Skinner, 447.) A college consists of a head, called by the various names of provost (præpositus), master, rector, principal or warden, and a body of fellows (socii), and of scholars also, besides various officers or servants, according to the peculiar nature of the foundation. A college is wholly subject to the laws, statutes, and ordinances which the founder makes, and to the visitor whom he appoints, and to no others. All elections, and the general management of a college, must be in conformity with such statutes or rules. If a college does not exceed its jurisdiction, the king's courts have no cognisance, and expulsion of a member is entirely within its jurisdiction, and therefore, in general, a mandamus cannot be had to restore a fellow to his fellowship (Comyn's Digest, 'Visitor,' s. 15); nay, more, where a college, as visitor, had removed an individual from a mastership in a school, not only has a mandamus been refused (Craford's case, Styles, 457), but the Court of Chancery refused to interfere by injunction (Whiston v. Dean and Chapter of Rochester, 18 Law Journal, Chancery, 478). If there is no special visitor appointed by the founder, the right of visitation, in default of the heirs of the founder, devolves upon the king, who exercises it by the great seal; and in such case it is to be exercised by the crown cyprés (or as near as possible) to the manner in which it was exercised by the founder and his heirs. (R. v. St. Catherine Coll., 4 Term Rep. 243.) When the king is founder, his successors are the visitors.

The general power of a visitor is to judge according to the statutes of a college, to expel and deprive for just reason, and to hear appeals. His precise powers are determined by the founder's statutes, and if there are any exceptions to his power, the jurisdiction in such excepted cases devolves on the king. Certain times are generally named in the statutes for visitation, but the visitor may visit whenever he is called in, it being incident to his office to hear complaints. So long as a visitor keeps within his jurisdiction his acts cannot be controlled, and there is no appeal from him, as was decided in the above-mentioned case of Phillips v. Bury. The visitors are not bound to any particular forms of proceeding, and, in general, want of jurisdiction is the only ground on which they are liable to prohibition. If a visitor's power is not limited or defined, he must use his best discretion. If a power to interpret the statutes is given to any person, as to the bishop of the diocese, this will constitute him and his successors visitors. The heirs of a founder cannot alter the statutes, unless such a power is expressly reserved; and it appears, that where the king is founder, his successors cannot alter statutes without the consent of the college, unless such a power is reserved. But as to the power to alter statutes, it must be observed, that in the case of the crown at least, it has not unfrequently been done, though such a power might now possibly be disputed, unless expressly reserved to the founder and his heirs by his original statutes. In Attorney-General v. Archbp. of York (2 Russell & Mylne, 468), Lord Brougham said, "No man can doubt what the powers of a visitor are. In practice they are perfectly uncontrolled, of removal, new appointment, variation, and alteration. They are, in truth, of a most extensive and arbitrary nature." But Lord Mansfield has expressed strong doubts whether a visitor can repeal or alter statutes without an express power given by the founder. (1 Burrows, 201.)

Whenever a visitor is appointed, the Court of Chancery never interferes with the internal management of a college; how far it exercises jurisdiction in matters pertaining to the management of the funds, on the ground that as to the funds of a college, those who possess the legal estate are in the situation of trustees, is a doubtful point. Certainly, in the case of charitable foundations, where the governors or visitors are trustees for the charity, and are found to be making a fraudulent use of their powers, the Court of Chancery can and will interfere on information (see 15 Ves. 314); and even where the founder has left directions in his will vesting the sole government and management of the charity in the visitors, the Court of Chancery will exercise control, where *such visitors are also trustees* of the charity estates. It is said, however, that such interference of Chancery with visitors, is only where both the legal estate and the receipt of the rents are vested in the visitors. (Att.-Gen. v. Middleton, 2 Ves. sen. 328; see Green v. Rutherforth, 1 Ves. sen., 473 & 475.) In colleges, when a new foundation is engrafted on an old one, it becomes part of the old one, and subject to the same visitorial authority, unless in the indenture of annexation by which the college takes the additional foundation a difference in the matter of visitation is expressly declared (R. v. Bishop of Ely, 1 W. Blackstone, 70); unless new statutes are given with the new foundation, in which case the college accepting the foundation will be bound in all respects by the new statutes, for they take the benefit *cum onere*. (See the cases collected in Grant on Corporations, 542, n.)

The validity of all elections in colleges must be determined by the words of the founder's statutes or rules. In the disputes that have arisen on elections, the point has generally been, whether the master's concurrence is necessary, or whether a bare majority of the electors, of which electors the master is one, is sufficient. (See, as to this, Grant on Corporations, 532, 538, 539.) In Catharine Hall, Cambridge, fellows must be elected "communi omnium consensu aut saltem ex consensu magistri et majoris partis communitatis;" and it was held by Lord Eldon, upon these words and another clause which follows, that no election was valid in which the master did not concur.

The statutes of Clare Hall, Cambridge, require "that the election of a fellow shall be by the master and the major part of the fellows present;" and here it was held, on reference to the chancellor, the Duke of Grafton (A.D. 1788), that a valid election might be made without the concurrence of the master. But this interpretation is obviously wrong, and is referred to with disapprobation in the case of Queen's College, Cambridge (5 Russell, 97), in which case the lord-chancellor, Lord Lyndhurst, in declaring his opinion with reference to the college then before him to be that the concurrent voice of the president was necessary in all elections of its fellowships, expressly rested his decision on the judgment of Lord Eldon in R. *v.* Catharine Hall, 4 T. R. With reference to the subject of election to and tenure of fellowships, two modern cases are deserving of notice as bearing upon the construction which the Court of Chancery puts upon college statutes: these are In re St. Catharine's Hall (1 McNaght. & Gord. 467), and exparte Edleston (1 De Gex, McN. & Gord. 742). The latter case is important as maintaining the principle that new statutes embodying old ones do, in the absence of any express intention to the contrary, get rid of dispensing (or remedial) statutes. Before dismissing this topic, it should be noticed, that the whole matter is now (1859) in a transition state, the statutes of the different colleges being under the revision of a committee appointed by the government for that (among other) purposes.

Colleges (13 Eliz. c. 10) could not grant leases of their land beyond twenty-one years, or three lives; and in such leases the accustomed yearly rent, or more, must be reserved, payable yearly during the term. By 18 Eliz. c. 6, in all leases made by colleges in the universities, and by the colleges of Winchester and Eton, one-third of the whole rent must be reserved in corn. By a very recent statute (21 & 22 Vict. c. 44), the subject of college leases and powers to sell and exchange has been materially affected. The Act enables the three universities of Oxford, Cambridge, and Durham, and their colleges, and the colleges of Winchester and Eton (*a*), to sell, enfranchise, and exchange lands, (*b*) to grant leases for agricultural, building, and mining purposes, and (*c*) to deal with the interests of lessees. Under the first head they are empowered to sell, enfranchise, and exchange through the medium and with the consent of the copyhold commissioners; under the second to grant agricultural leases for a term not exceeding 21 years at a rackrent, building and repairing leases for a term not exceeding 99 years, and mining leases for a term not exceeding 60 years; and under the third, to purchase the interests of lessees, either by payment of a gross sum of money or by an annual charge upon the lands: at the same time power is given them to raise the necessary sum or sums by mortgage, with the consent of the copyhold commissioners. Power is also given them to raise money for other purposes, such as the erection and improvement of university and college buildings, and of the buildings on their estates (§ 27); and the Act is expressly declared to extend to lands held by them in trust or for special endowments. The Mortmain Act of 9 Geo. II. c. 36, which has put considerable obstacles in the way of gifts of land or money to be laid out in land in England for charitable purposes, does not extend to the two universities of Oxford and Cambridge, or to colleges in the two universities, nor to gifts in favour of the scholars of Eton, Winchester, and Westminster. This statute contained a restriction as to the number of advowsons which a college in either of the universities was allowed to hold; but this restriction was removed by 45 Geo. III. c. 101, having been found, as the preamble to this statute sets forth, injurious to learning. These colleges can therefore now purchase and hold as many advowsons as they please.

A collegiate church is a church that has a college or chapter of canons, but no bishop, and yet is under the authority of a bishop. (See Ayliffe's 'Parergon,' p. 167.) These collegiate churches are sometimes simply called colleges. In the case of Manchester College, a mandamus was directed to the Bishop of Chester, as warden of Manchester College, to admit a chaplain. The bishop happened also to be visitor of the college. It was held by the King's Bench, that in the case of a spiritual corporation the jurisdiction was in that court, unless there was an express visitor appointed; and the court interposed in the present case because there was no separate visitorial power then existing, owing to the union of the wardenship and visitorship in the same person. (Strange, 797.) This case was afterwards provided for by an express Act, 2 Geo. II. c. 29.

As to the relation between the English universities and the colleges within their limits, and the nature of a college in the English universities, considered simply in itself, see UNIVERSITY in this DIVISION; and CAMBRIDGE and OXFORD, in the GEOGRAPHICAL DIVISION.

The statutes of all the old colleges in England are in Latin; and, indeed, with the exception of some comparatively modern endowments, probably all college statutes are in Latin. Those of Eton College, of Trinity College, Cambridge, and of St. John's College, Cambridge, which may serve as specimens of the statutes of such foundations, are printed in the Education Reports of the House of Commons, 1818; and now the old statutes of the colleges of Oxford and Cambridge have been printed by the commissioners for enquiring into the two universities, the former in 1853, the latter in 1852. For the early history and privileges of the universities, see, among others, Wood's 'Historia Antiq. Oxon,' Ayliffe's 'State of Oxford University,' and Dyer's 'Privileges of the University of Cambridge.'

Meiners ('Geschichte der Enstehung und Entwickelung der Hohen Schullen,' &c., Göttingen, 1802, vol. i.) has given an interesting chapter on the origin of colleges in universities. The colleges in the University of Paris were the first institutions of the kind in Europe, though it is a mistake to suppose them older than the university itself.

The terms college and university have been often confounded in modern times, and indeed are now sometimes used indiscriminately. Some of the incorporated places of learning in the United States, which confer degrees, are called universities, and some are called colleges, though there is in fact no distinction between the two. Some of these institutions called colleges contain the schools or departments of arts, law, medicine, and theology; and some that are called universities contain only those of arts, law, and medicine. Some of these colleges are more limited as to the objects of instruction, but still confer degrees. If we look to the origin of colleges, and their connection with universities, it will be evident that the indiscriminate use of these terms is incorrect, and tends to lead to confusion. When an incorporated college, such as the College of Surgeons in London, is empowered to confer a degree or title after examination of candidates in a single department, some other name would be more appropriate. The word Academia, which is the most modern of all the terms applied to places of higher instruction, has been most usually applied to endowed corporate bodies which have for their object the improvement of some particular science or some particular branch of knowledge, in some cases with the power to confer degrees in such particular science, &c., and sometimes without this power. Yet the terms academia and university have also often been used, and now are used indiscriminately. (Meiners, vol. iv., 'On the Different Names of High Schools;' Huber and Newman, 'The English Universities,' vol. i.; and Savigny's 'Geschichte des Römischen Rechts im Mittelälter,' vol. iii., ch. 21.

The history of the Scotch universities shows that the terms college and university were, both at the time of the foundation of these institutions and subsequently also, used with little discrimination; and this carelessness in the application of the terms had led to anomalies in their constitution, and no little difficulty in comprehending the history and actual constitution of these bodies. (See the 'Report of the Royal Commission of Inquiry into the State of the Scotch Universities,' printed 1831; and Malden's 'Origin of Universities,' London, 1835.)

In France, the term college signifies a school, though the constitution of a French college is very different from that of our grammar-schools. It comes nearest, perhaps, to a German gymnasium. Of these colleges there are about 320, every large town having one of them. They are maintained by the towns, their heads and professors being paid out of the revenues of the communes. They are all under the superintendence of the University of France. There are also about 40 imperial colleges, in which the directors (*administrateurs*) and professors are paid by the state. The College Impériale of France, founded by Francis I., has above twenty professors, who lecture on the various sciences and the Oriental languages. (See 'Journal of Education,' No. III., 'On the State of Education in France.')

On the subject of colleges, from a legal point of view, the reader is strongly recommended to peruse an admirable argument on the rights of the fellows of Harvard University by the late Mr. Justice Story ('Miscell. Writings,' p. 294).

COLLIDINE ($C_{16}H_{11}N$). An organic base found in *bone oil*. It is isomeric with *xylidine*.

COLLIMATION, ERROR OF. In most instruments the line of sight is supposed to have a certain relation to other parts. Thus in a transit telescope it ought to be perpendicular to the horizontal axis, in a circle or quadrant it should be in a horizontal or vertical direction when the reading of the limb is 0° or 90°. When this is not the case, the difference between the existing and required positions is called the *error of collimation*, which must be carefully ascertained, and be corrected or allowed for, or eliminated in the mode of conducting the observations. This will be particularly explained as each instrument comes under our notice. Many readers will have a general notion of the error of collimation from the mode in which a workman tries the truth of his square, or of the mason's level, which in principle is nearly allied to the methods of astronomers. When the telescope was originally applied to astronomical instruments, the mystery of ascertaining the true direction of a line which could not be mechanically examined, presented considerable difficulties to some observers. Hevelius of Danzig never could be induced to apply telescopic sights to his sextants or quadrants, and in consequence of this prejudice much of the labour of his long and active life was completely wasted.

COLLIMATION, LINE OF, the line of sight in any astronomical or geodesical instrument. [CIRCLE.] Where a telescope is used, this name is given to the line joining the centre of the object-glass and the intersection of the fine wires or spiderwebs in its focus, this being the direction of any object which is there seen bisected by the observer.

COLLIMATOR, the name given by Captain Kater to his contrivance for determining the error of collimation in any principal instrument, without the reversal of the instrument itself. This reversal, troublesome in all large instruments, and in mural circles and quadrants, is forbidden by their construction. We shall give a sketch of Captain Kater's collimators and those antecedent to his invention, and a drawing and description of a *level* collimator, which on the whole we think best suited for common use. Where the adjustments, &c., mentioned are not described, the reader will find them in the article CIRCLE.

On referring to the description of each instrument, it will be seen that the determination of the error of collimation requires—1. A well-defined object, of which the direction remains unchanged; 2. A reversal of the instrument, similar to that of the mason's level; 3. For angular instruments, a power of determining the relation of the direction of that object to a vertical line. Now a near object cannot be seen on the wires of a telescope when they are in the focus of the object-glass, and a distant object is very seldom sufficiently steady or sharply defined. This want may be supplied by a second telescope, having its axis parallel to the axis of the telescope under examination and nearly in the same right line, which has cross-wires in its focus; the object-glasses being towards each other. As parallel rays falling on an object-glass converge to the focus, so rays diverging from the focus become parallel after refraction at the object-glass, and emerge as if they came from a real object at an infinite distance; hence the cross-wires in the supplementary or collimating telescope will be seen distinctly in the *direction* of the line joining the cross and the centre of the object-glass, in whatever part of the cylinder of issuing rays the eye may be placed. Great care is requisite in adjusting the wires of the collimating telescope exactly to focus, especially if a short telescope be used; but the axes of the two telescopes need only be approximately in a right line.

In many of the private observatories in England, a metal plate with sharp lines or dots engraved upon it, is firmly secured to an outside stone and viewed through a lens fixed in the wall of the observatory, the distance between the lens and the mark being equal to the focal distance of the lens. It is evident that such a mark may be used for determining the error of collimation in altitude of a reversible circle, and in all cases where merely a distinct and distant object is required. If the position of the mark be permanent, and the focal length of the lens be considerable, this may be advantageously used as a *meridian mark* [TRANSIT]; but then the lens should have a separate support within the observatory, and the position of the mark should be jealously watched and verified. Dr. Rittenhouse first made use of this substitute for a distant mark ('American Philosophical Transactions,' vol. ii. p. 181); and we believe Dr. Maskelyne at one time used an adaptation of the same principle, namely, a cap with a lens of long focus, slipping over the object end of his transit telescope, to view the south meridian mark at Greenwich, which was too near the observatory to be seen distinctly.

The collimating telescope and its cross-wires are thus made to supply the want of a distinct, distant, and immovable object. In the 'Astronomische Nachrichten,' No. 43, Professor Gauss, after enunciating the optical property above mentioned, used it for measuring the intervals between the wires of a transit telescope by a theodolet, which viewed them through the object-glass of the transit. In No. 61 of the same work, Professor Bessel applied the same principle to a still more important purpose, that of determining the horizontal flexure of the telescope of his meridian circle. After taking out the object-glass and eye-piece of this instrument (or the instrument might have been raised out of the way), he placed two collimating telescopes, one to the north and the other to the south of the circle, looking into each other, and nearly in the horizontal line which passed through the centre of his instrument. These he adjusted to have their cross-wires apparently upon each other, when the two object-glasses and the two crosses are evidently all in the same right line. The object-glass and eye-piece were then replaced in the circle telescope, and the angle between the two crosses of the collimator measured, which would have been exactly 180°, without flexure; hence the difference from 180° was the double horizontal flexure of the circle telescope. Bessel further remarks, that a vertical telescope turning freely round in its collars, and having a cross level attached, might be used for determining the true zenith point of any instrument, without reversing the latter. The date of this publication is July, 1824.

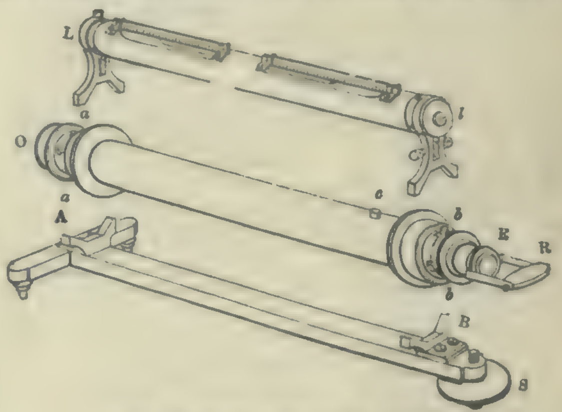
Captain Kater, who had not heard of either of these memoirs, gave, in the 'Philosophical Transactions,' 1825, p. 147, a description and figure of a *horizontal floating* collimator. This is a telescope laid horizontally upon a block of cast iron, which floats in a vessel filled with mercury. This collimator was designed for determining the *zenith point* of mural and other irreversible circles. The cross of the collimating telescope is observed by the circle telescope in one direction, suppose to the north, and the divisions read off. The trough of mercury with the collimator floating in it, is then transported to the south of the circle, the cross again bisected, and the divisions read off as before. If the angle which the line of sight of the collimating telescope makes with the horizon be supposed to be unchanged by this change of place, it is clear that half way between the means of the two sets of readings is the reading corresponding to the vertical position of the circle telescope. Again, as the difference of the north and south mean readings would equal 180°, if the collimating telescope were truly horizontal, half the excess of this difference above 180°, or half the defect from 180°, will be the angle which the collimating telescope makes with the horizon. We believe however that, in addition to the trouble of moving such an apparatus, the permanence of the position of the collimating telescope could not be relied upon if at all disturbed.

In the 'Philosophical Transactions,' 1828, p. 257, Captain Kater proposed a very much-improved form of this instrument, which he called the *vertical* floating collimator. The iron float is here a ring swimming in an annular trough, and the telescope, which is placed vertically, has a clear view through the centre of the float and trough. This collimator may be placed below the instrument to be examined, when the collimating telescope will have its object-glass uppermost, or, as is most usual, above the instrument, when the collimating telescope looks downwards. A smooth rotatory motion upon rollers can be given to the annular trough, when it is evident the line of sight of the collimating telescope will either be and continue to be vertical (supposing the position of the float to be permanent), or will describe a conical surface of which the axis is vertical. Hence, if the cross be bisected in two opposite positions of the collimator by the telescope of a circular instrument, the mean of the two readings will be the reading of the zenith of the instrument.

It will, generally speaking, be convenient to adjust the axis of the collimating telescope truly vertical. To do this first observe the position of the cross by a circle or transit telescope, turn the collimator half round, and note the position again; then, by placing a small weight upon the float, bring the cross half way between the two observed positions. Turn the collimator a quarter round and perform the same adjustment for this and its reversed situation. The axis of the collimating telescope is now truly vertical. From some trials, which however we must admit were not made under favourable circumstances, we do not think the vertical floating collimator capable of giving results as accurate as may be obtained by other means; but it ought also to be stated, that there is a good deal of difference of opinion among practical astronomers upon this point.

In the accompanying figure we have represented a more portable, and perhaps a more accurate instrument for determining the error of collimation, and also the position of the horizon, than either of the floating collimators.

The three parts of which this collimator consists have been separated from each other for easier comprehension. The telescope O E rests with its ground cylindrical collars, *a a*, *b b*, in the rectangular Y's, A, B of the stand. These collars should be truly cylindrical, and, if possible, exactly equal. There are cross-wires which must first of all be placed correctly in the focus of the object-glass, when the screw *c* is to be tightened. To adjust the cross-wires bring the intersection of the cross to bisect any distinct and immovable object (the wires of another telescope, for instance), turn the telescope half round in its Y's, and then, by releasing one of the four adjusting screws (the heads of which are seen near *b b*), and screwing up its antagonist, bring the cross *half way* back to coincidence, and complete the coincidence by screwing S. When this has been done satisfactorily, adjust the cross in the transverse direction by the other two screws, and it will then be found that the telescope can be turned round, without any apparent change of place in the cross-wires, that is, the line of sight is in the axis of the collars or parallel to the axis. The reflector R, which is merely to throw the light of the sky or a lamp upon the wires, may now be put on.



Level Collimator, Troughton and Simms.

The collimator being thus adjusted, is to be set to the north or south of the circle under examination, and at the same height as the centre of the telescope, when the axis of the collars is to be made horizontal by the reversible level *Ll*, and the foot screw S. When the cross of the collimator is bisected by the wires of the circle telescope, the telescope is horizontal, and the mean reading of the circle microscope is the reading of the *horizontal point*, which, if the circle reads altitudes, should be 0°, and if zenith distances, should be 90°. The difference from these values is the error of collimation. By setting the collimator to the other side of the instrument any error of flexure may be detected.

We have said that the cylindrical collars should be perfectly equal, but it is not easy to make them so. The difference is easily ascertained by reversing the telescope in its Y's, end for end, and again applying the level. Suppose the level to have shown perfect horizontality before reversing, and that afterwards the reading towards O exceeds that towards E, by m''. It will easily be seen that $\frac{m''}{4}$ must always be *subtracted* from the indications of the level towards O. It is equally evident, that if, after the above correction is made, the object end O appears too high by n'', that the true angle with the vertical is $90 + n''$, or that the reading of the circle should show n'' of depression. The different cases which may occur present no difficulty. If the collars are truly cylindrical and the level a delicate one, such a collimator should show the true horizontal point within $1''$. The telescope should not be very small, not less than 12 inches.

It would scarcely be just not to notice under this head an instrument by Roëmer, which has as much merit, as an invention, as any of these which we have described. It consists of two equal lenses fixed in a tube at a distance somewhat exceeding their focal length, with a system of wires in the focus of each, between the glasses. By applying the proper eye-piece at each end, the near wires, and consequently objects through the most distant object-glass, are made visible. The two object-glasses and the crosses of the wires being all adjusted in the same straight line, it is evident that, on looking in at each end of the tube, objects 180° apart will be seen on the crosses. Roëmer called this tube an *amphioptron*, or *reciprocal telescope*, and used it for the transit adjustment in collimation of his *rota meridiana*. (Horrebow, 'Basis Astronomiæ,' p. 97.)

For further details, see Pearson's 'Practical Astronomy,' vol. ii. p. 446, plate xxi.

COLLISION, IMPACT, or PERCUSSION OF BODIES, is that part of Dynamics in which are contemplated the effects arising from the striking against each other of two bodies, one or both of which are in motion, and answers to the *choc des corps* of French treatises.

It is usual to treat the first principles of this subject by supposing the bodies in question to be spherical; and for the following reason: When a body receives a blow, if it be free to turn as well as to move forward, a rotatory motion is, generally speaking, produced, as well as a motion of translation. But if the direction of the blow be in a line which passes through the centre of gravity, no rotatory motion is produced. Now if two equal spheres move upon a plane, it is obvious that when either strikes the other, the direction of the blow passes through the centre of gravity. Making use then of equal spherical balls, of the same or different weights, moving upon a level plane, let it be remembered that all conclusions apply equally to bodies of any form, having no rotatory motion, and striking each other in such a way that the line joining their centres of gravity passes through the point of contact at the moment when they strike.

The simple mathematical theory of impact proceeds, like other mechanical theories, upon suppositions which can only be approximately obtained in practice. For instance, if in the preceding supposition the level plane and the balls exercise any friction on each other, the consequence will be that the balls will begin to roll on the table, even though the blows which set them in motion pass through their centres. To the existence of this friction are due many phenomena which a game of billiards will present, and which will not result from the common theory. Let the table, then, be supposed to exert no friction on the balls, so that one of the latter, struck by a blow the direction of which passes through the centre, will move along the table without rolling.

Let us now suppose the ball A to be impelled directly towards an immovable obstacle, such as an upright ledge at the end of the table. On striking this ledge, the ball will, generally speaking, recoil more or less. Some substances will hardly give any recoil, while others will send the ball back with nearly the same velocity as that of its approach. This spring or elasticity is more easily measured than explained; it arises in the following manner: At the moment of impact, the ball compresses the part of the obstacle against which it strikes, which pressure continues until the reaction of the obstacle has destroyed all the velocity of the ball. At the same time the parts of the ball close to the point of impact have been compressed in a similar manner. If then there were no effort in the parts of the obstacle nor in those of the ball to recover their former position, the ball would remain at rest, close to the obstacle. If the recoil were complete, that is, if the parts of both bodies endeavoured to recover their position with a force equal to that which disturbed them, the recoil would rapidly but gradually create in the ball a velocity equal to that with which it approached. These two cases are the theoretical extremes which it is most probable no material bodies attain: in the first case they are said to be wholly inelastic, and in the second the elasticity is said to be perfect. But if only a fraction e of the velocity of approach be restored, then e is said to be the measure of the elasticity of the bodies.

In treating of the theoretical effects of impact, many authors have ascribed to bodies the hypothetical property of perfect hardness or incompressibility. This, however, is quite gratuitous, for Mr. Hodgkinson has not found in the course of his experiments (see 'British Association Reports,' vol. iii. p. 534), any matter perfectly fulfilling these conditions. Hence the value of ϵ for all known substances is a positive proper fraction, which represents the ratio that the force of restitution bears to the compressing force, that is,—

$$\epsilon = \frac{\text{force of restitution.}}{\text{force of compression.}}$$

This quantity ϵ must not be confounded with the *modulus of elasticity*. [ELASTICITY.]

The value of ϵ for some common substances is as follows:—

Glass	=	0·94	Bell-metal	=	0·67
Ivory	=	0·81	Cork	=	0·65
Steel	=	0·79	Brass	=	0·41
Cast-iron	=	0·73	Lead	=	0·80

If the striking bodies have spherical forms so that the contact may take place, at the first instant, in a point, their surfaces about that point will have their figures changed; and if the bodies have different degrees of hardness, an indentation may take place in that which is the least hard, the other penetrating to a certain distance in it. When the bodies are soft, like balls of wet clay, the change of figure produced by collision is manifest; but when two balls possess an elasticity which is nearly perfect, they so far recover their original figure after impact, that the change is not perceptible: it may be rendered evident, however, by covering one of the spheres with ink and suffering it to impinge on the other, the latter then receives a stain which, instead of being a point, is a circle of sensible magnitude; and this proves that the surfaces must have been flattened at the point of impact.

Impact has been termed a "pressure of short duration;" but practically there is a great difference between the effects of pressure and impact: thus, a very large weight will be required to press a nail into a block of wood, which may be readily driven into it by a small hammer; and the reason is, that a longitudinal compression of the nail towards the head takes place, which is followed by restitution, and these actions follow each other successively, and the nail enters by a kind of *vermicular* action, like that of a *worm* progressing through the earth.

Also, when impact is employed to communicate motion to one body relatively to another, the effect produced depends greatly on the immobility of the latter; thus, many more blows will be required to drive a nail into a *loose* board, than would suffice if the latter were fixed; although, in certain cases, as in the breaking of minerals, &c., the effect of impact is diminished by a firm support. Here, probably, the effect of momentum on the successive particles is interfered with by a contrary momentum generated by restitution.

In order to account for the effect of percussion in impelling a body, a wedge for example, being much greater than that of mere pressure,—it may be observed that both effects depend on the product of the mass of the impelling body and its velocity: but, when a body moves in consequence of pressure, the velocity is extremely small; therefore, in order that the effect of simple pressure may be equal to that of percussion, the mass imposed must be very great. It is evident, however, from what has been said, that the two forces are of the same nature. It should be added, here, that the shock produced in a material, when divided by a wedge, or penetrated by a nail, either of these being driven with a force produced by a sudden blow of a hammer may, by displacing the particles of the material, diminish their cohesive power; and this may be, in part, the reason that the effect of percussion often exceeds that of a weight many hundred times greater than that of the hammer.

The force of elasticity is very different in different bodies: spheres of glass are those in which the force of restitution (after impact) approaches nearest to the force of compression; and, in such spheres, the ratio between the forces is as 15 to 16: in spheres of ivory the ratio is as 8 to 9; and in spheres of steel, as 5 to 9.

The bodies upon which experiments on collision are usually made are generally of a spherical form; in order that when they impinge upon one another directly it may be indifferent at what part of the surfaces of the bodies the contact takes place: the bodies are usually suspended by a string or rod from fixed points; and they are made to impinge upon one another while describing circular arcs, in a vertical plane, about the point of suspension. The absolute momentum, or quantity of motion in a body, is represented by the product of its mass and the velocity with which it is moving: but the effects of the collision of two bodies depend on their relative velocity, or that with which they approach to, or move from, one another; this is consequently the sum of the absolute velocities when the bodies, in approaching each other, move in opposite directions, and the difference when they move in the same direction.

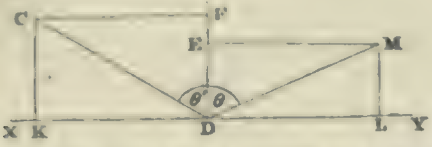
The principles upon which are determined the velocities after impact of different balls which strike one another are as follow:—

1. If two perfectly inelastic balls move towards each other in opposite directions, and with velocities inversely proportional to their weights or masses, they will destroy each other's velocities and remain at rest. Thus if A were twice as heavy as B, but if B moved twice as fast as A, there would be no motion after impact. [MOMENTUM; MOTION, LAWS OF.] Let a be the velocity of A, and b of B; then A and B being expressed in the same units of weight, and a and b in the same units of length and time, the preceding condition is fulfilled when $Aa = Bb$.

2. If the same velocities be added to or taken from both balls, so that their rate of approach is not altered, the forces exerted in the shock will not be altered, nor will the rate of recess after the shock. Thus a cannon-ball rebounding from a wall, both having the motion of the earth, strikes with the same force and rebounds in the same manner as it would do if the motion of the earth were taken from both, or if the earth were at rest.

Now, suppose the ball A (which is so small that its size may be neglected) to approach obliquely towards the obstacle XY, say in the direction CD. Let CD be the velocity, or length moved over in one second. Then [VELOCITY] the velocity CD is equivalent to the two velocities CK and KD. The first is destroyed, and then partially restored by the impact; the second remains unaltered, except by the friction at the moment of impact, which we do not consider. If then we take DL equal to KD, and draw LM perpendicular to XY, and in length such a fraction of KC as e is of 1, the ball will move after impact with the velocities DL and LM, that is, with the velocity DM in the direction DM. If the system were perfectly inelastic, the ball would proceed along DL; if perfectly elastic, ML would be equal to CK, and DM and CD equally inclined to XY. If the size of the ball be taken into account, XY must be supposed to be a line parallel to the obstacle, and distant from it by the radius of the ball.

Fig. 1.



Direct impact and collision. Let the masses of the two balls or material particles be m and m', and let them move with uniform velocities v and v' in the same direction along a straight line, v being greater than v', so that m overtakes m'. Let u be the common velocity of the two balls when the compression at the moment of impact is a maximum; let P be the momentum spent in producing this compression, and eP the momentum acquired during the restitution of the form of the bodies, e being the coefficient of elasticity. Let V and V′ be the velocities of the balls when collision ceases. Hence, we have the three following cases:—

(1.) $m\,v$ = momentum of m at the beginning of collision.
P = momentum spent in producing compression.
$m\,u$ = momentum of m, when compression is a *max.*—

$$\therefore m\,v = m\,u + \text{P}.$$

(2.) $m'v'$ = momentum of m' at the beginning of collision.
$m'u$ = momentum of m', when compression is a *max.*—

$$\therefore m'v' = m'u - \text{P}.$$

(3.) At the instant when collision ceases, we have similarly,

$$m\,\text{V} = m\,u - e\,\text{P}.$$
$$m'\text{V}' = m'u + e\,\text{P}.$$

from which equations we shall get

$$u = \frac{m\,v + m'v'}{m + m'} = \frac{m\,\text{V} + m'\text{V}'}{m + m'}$$

$$\text{P} = \frac{m\,m'}{m + m'}\,(v - v')$$

$$\text{V} = \frac{m\,v + m'v'}{m + m'} - \frac{e\,m}{m + m'}\,(v - v'), \text{ and } \text{V}' = \frac{m\,v + m'v'}{m + m'} + \frac{e\,m}{m + m'}\,(v - v').$$

Oblique impact and collision. In oblique impact we assume that the mutual action of the balls during collision is along the line joining their centres at the instant when compression is a maximum, and along that line only; that is, we assume the balls to be perfectly smooth. Hence, if a smooth ball impinges obliquely on a smooth plane, the line of reaction of the plane will be perpendicular to its surface, and the momentum of the impinging ball will be affected along that line only.

In *fig.* 1, let the ball C impinge at D, and be carried away to M; let v and v' be the velocities before and after impact, and which are therefore proportioned to CD and DM.

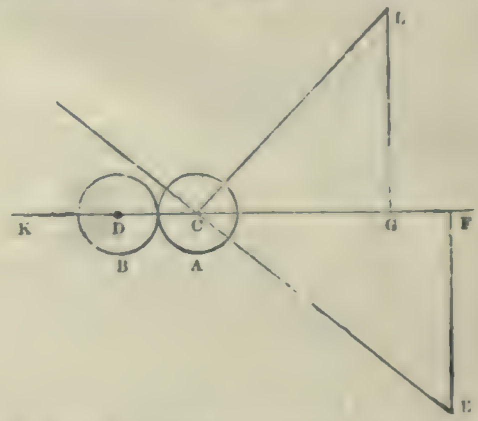
$$\therefore \frac{v}{v'} = \frac{\text{CD}}{\text{DM}} = \frac{\dfrac{\text{CF}}{\sin\theta'}}{\dfrac{\text{ME}}{\sin\theta}} = \frac{\text{CF}}{\text{ME}}.\frac{\sin\theta}{\sin\theta'} = \frac{\sin\theta}{\sin\theta'}$$

$$\text{and } e = \frac{\text{DE}}{\text{DF}} = \frac{\text{FC}}{\text{ME}}.\frac{\text{DE}}{\text{DF}} = \frac{\dfrac{\text{FC}}{\text{DF}}}{\dfrac{\text{ME}}{\text{DE}}} = \frac{\tan\theta'}{\tan\theta}$$

The equations for the impact of two smooth balls are similarly formed, and may be easily understood from their analogy to those given above for *direct* impact. Thus, suppose two balls A and B to move in directions *oblique* to one another, and to strike each other. Decompose the velocity of each ball into two, one in the line joining the centres at the moment of impact, and the other perpendicular to it. The pair of velocities perpendicular to the central line will not be altered by the impact; and as far as the remaining velocities are concerned, the case is precisely the one already solved. Find the velocities in the central line as altered by the impact, compound them with the perpendicular velocities which remain unaltered, and the resulting velocities and directions will be those with which the balls will proceed after the impact.

To take the most simple case, suppose the ball A, moving in the direction EC, and with the velocity EC, to strike the ball B, which is at rest. Join D and C, the centres of the balls, and decompose EC into FC in the line joining the centres, and EF perpendicular to it. Then A will only strike the ball B with the velocity FC. Suppose that by the preceding rules it is found that A, striking B at rest with the velocity FC, will be thrown back with the velocity CG, while B is struck forward with the velocity DK. Then B will receive this velocity, and this one only; as to A it has after the impact acquired the velocity CG, which it combines with the velocity GL, equal and parallel to EF; so that CL represents the velocity and the direction of the motion of A after the impact.

Fig. 2.



In every case of impact, when the balls approach one another with uniform velocities, the centre of gravity of the balls moves uniformly, and in a straight line. After the impact, though the directions and velocities of the balls may have changed, yet their centre of gravity still continues to describe the same line, and with the same velocity as before. This proposition is proved in all works on elementary mechanics.

The following conclusions will now be readily deduced by any one who understands the preceding results:—

1. If two inelastic balls move in the same direction, they do not separate after the impact, but either move on with a common velocity, or are reduced to rest. If both move in the same direction, the velocity after impact is $(\text{A}a + \text{B}b) \div (\text{A} + \text{B})$; but if they move in different directions, the motion after impact is in the direction of that ball of which the momentum ($\text{A}a$ or $\text{B}b$) is the greatest, and the velocity is $(\text{A}a - \text{B}b) \div (\text{A} + \text{B})$ or $(\text{B}b - \text{A}a) \div (\text{A} + \text{B})$. When the momenta are equal, there is no motion after the impact. If $b = 0$, or if one of the balls be at rest before impact, the velocity after impact is $\text{A}a \div (\text{A} + \text{B})$. To deduce these results, make $e = 0$ in the formulæ, and give the velocities their proper signs.

2. If two perfectly elastic balls move in the same direction they separate after the impact, the velocity of the foremost being augmented from b to $b + 2(a - b)\text{A} \div (\text{A} + \text{B})$. But the velocity of the hindmost is either retarded, altogether destroyed, or made to change its direction, the algebraical formula for the velocity after impact being $a - 2(a - b)\text{B} \div (\text{A} + \text{B})$. This is nothing when B exceeds A, and when b is to a as $\text{B} - \text{A}$ is to 2B. And according as b is to a in a less or greater ratio than the preceding ratio, A's velocity is or is not altered in direction.

If two perfectly elastic balls move in opposite directions, that of A being called positive, the velocities of A and B after impact are determined in magnitude and direction by the formulæ

$$a - (a + b)\,\frac{2\text{B}}{\text{A} + \text{B}} \text{ and } -b + (a + b)\,\frac{2\text{A}}{\text{A} + \text{B}}.$$

4. If two perfectly elastic balls be equal in magnitude, the velocity of each after the impact is that which the other had before the impact, both in magnitude and direction.

5. In all cases perfectly elastic balls recede from each other after impact with the same velocity with which they approached before impact; since if $e = 1$, $v - u = a - b$. But in every other case the rate of recess after impact is the same proportion of the rate of approach before impact which e is of 1.

6. The *vis viva*, or product of the mass and *square* of the velocity, of a couple of perfectly elastic balls is the same before and after impact; in every other case it is less after impact than before.

For further mathematical developments and deductions from these general formulæ, we may refer especially to Professor Price's treatise on 'Infinitesimal Calculus,' vol. iii. c. 8 and 10; to Golding Bird's 'Natural Philosophy,' p. 134, *et seq.*; and to Professor Walker's treatise on 'Mechanics,' c. vii. p. 173.

COLLISIONS AT SEA. The accidental contact of vessels which traverse the ocean and the numerous channels and roadsteads of Europe, is a painful feature of commerce; because the extension of commerce must increase in fearful ratio the chances of calamities which are known as collisions at sea.

These calamities present to us danger to human life in a new aspect. Its novelty consists not so much in the peculiarly frightful nature of accidents of this class, as in the *causes* which produce them. In the olden time, or even within the memory of the present generation, when ships ran foul of each other, it was seldom that loss of life attended these mishaps; and in the Channels the amount of damage would frequently extend, perhaps, to the loss of an anchor or two, the starting of a butt-end, or, perhaps, a crash not difficult to patch up until some port could be gained. The form of our shipping in those days was rather adapted to the carrying of burthens than for speed; and consequently, from the fuller lines of the bow of the ship the blow was distributed over a greater surface of timber, when ships were, moreover, built with greater strength.

Now, however, not only do ships, as a general rule, possess increase of speed, but their lines are so adjusted as to present the least possible resistance in their forward end, and their bows are absolutely wedge-like. Nor is this all; for instead of the fore-part of the stem-piece itself being 12 or 14 inches in thickness, many iron steamers of thousands of tons burthen present no more breadth of stem at the fore-part than belongs to a London wherry. Hence, in these times, circumstances seem to *conspire* towards the increase of danger in collisions; and from the combined influences of increased speed and the sharpness of stems, vessels at sea are really and daily in danger of being literally cut in two. In reading tales of chivalry, our horror may have been deep at the description of prowess and strength which would cleave a man to the brisket: shall we be unmoved now, when we hear of a fine ship being in like manner, and without any warning, cut through timbers and bulkhead, and windlass and deck, almost to the fore-mast itself? Yet such *has occurred*, and is always threatening. In the collision between the Mail and the Excelsior, off Birkenhead, in 1856, even worse than this happened, for the whole of the unfortunate passengers who were sleeping forward were in one instant crushed, and mangled, and destroyed in the general wreck, from the *cutting-down* blow of a sharp stem!

Thus collisions at sea must be viewed as evils of very great magnitude, requiring energetic and watchful legislation for their prevention; for, in addition to the changes in the mere forms of shipping referred to, another element of mischief is looming in the fast-diminishing distance,—it is the increased *size* of shipping. Collisions, it is true, have *only* hitherto sent *dozens* of our fellow-creatures suddenly into eternity; but the period is at hand when these dozens may become *hundreds*, perhaps *thousands*, unless some more powerful influences are called into more active operation to prevent it. It is peculiarly the duty of a Cyclopædia to grapple impartially with any question in arts and sciences resulting from *progress*, and to examine the various subjects of its contents, in order to detect new features which menace, or to watch known aspects which indicate changes; and this subject will accordingly receive our proper attention.

The great difficulty of the question of collision is perhaps the prevailing erroneous idea that it is merely a nautical question; while, in reality, it affects directly the whole community, as passengers of ships are the members alike of coast-resident and inland families; and it is remarkable that ships carrying only their ordinary crews seem to have been less liable to the accidents under consideration than those carrying passengers.

An extraordinary fact has been elicited from the careful investigation of accidents which occurred in 1856. One would naturally have expected to find that collisions would especially occur during the time of fog or haze, or certainly in the hours of darkness; but the editor of the 'Nautical Magazine' has produced a statement or abstract in that valuable periodical, in which we find the following table of the collisions in 1856. ('Nautical Mag.,' Nov., 1857):—

STATE OF WEATHER.	BY DAY. (6 A.M. to 6 P.M.)	BY NIGHT. (6 P.M. to 6 A.M.)	TOTAL COLLISIONS.
Dark	0	31	31
Dark and clear . .	2	4	6
Very dark . . .	0	5	5
Hazy	12	80	92
Cloudy . . .	9	20	29
Thick and foggy . .	5	19	24
Clear	36	81	117
Unknown . . .	2	10	12
Total . . .	66	250	316

From the above it actually appears that the *greater number* of collisions occur in *clear* weather, and the *least* number in dark or thick weather. To whom, then, can we, in a spirit of impartiality, impute culpability? When mariners themselves are so seriously implicated, we can only turn imploringly (as in the cause of humanity) to the authorities themselves. It is easy to accuse even these of neglect, but it would really be difficult to convict them even of indifference. The collection of materials for the above table is of itself a proof that the government of the country is alive to the importance of the question, that the naval heads of the Board of Trade are anxious to remedy this crying evil, this standing blot upon our *seamanship* and *vigilance*. The only inference an impartial public can draw is, that the *onus* and *odium* of the fault must rest, in a great measure, with the officers of ships themselves. It is well to consider if the comparative exemption of ships of war from collision arises from better discipline—better look-out. From the above it is evident that,

1st, More attention is called for on board merchant-ships generally;
2nd, The rules of the road *by day* may be defective;
3rd, The rules of the road *by night* may be defective also.

Probably legislation can only partially present a remedy for the defect first mentioned. Surely it is beneath the dignity of a British sailor, either to *run into* or *be run into* by any craft that floats. There was a time when *vigilance* formed the very key-stone in the character of the English seaman; it is hoped the present generation will maintain this character. It may be that the changes from sailing to steaming have unsettled the habits of seamen, and that, in the confusion, accidents, for a time unavoidable, may occur; but is it not reasonable to expect that every merchant vessel should have at least one able seaman in each watch whose duty and responsibility should be to prevent collision? Surely precautions and responsibilities which attach to railway officials, might without hardship be enforced on, and attached to, officers of the mercantile marine, where such very serious interests of life and property are at stake. But legislation may be greatly assisted by some conventional, better-understood rules among ship-masters themselves; as for instance, larger steamers, being often difficult to steer readily, and drawing more water, should claim a proper consideration from smaller ones. A few examples made by the Board of Trade, in the salutary punishment of obstinate or unyielding masters of small craft, might, in river or estuary navigation, partially remove danger.

As regards the second assumption, namely, defective rules of the road by day, it is extremely difficult to know where to place the limit between stringent law and freedom of judgment. Nay, it may even be demonstrated, that compliance with any known law or rule as to the movement of the helm, *irrespective of the judgment of the helmsman*, would prove in many cases disastrous; and those who attempt by diagrams to illustrate any proposed rule, ought to remember that, in order to render their illustrations acceptable and useful, the vessels must not only be supposed to answer their helms with equal readiness, but their speed must be precisely similar. A discretionary power in commanders, by day, seems to be more valuable than all regulations, excepting such good old ones for sailing-vessels as starboard tack hold on, port tack give way, &c.; and for steamers, *a good look-out, a good man at the helm*, and *passing each other on the port side, &c.*, ought to be enough.

In crowded rivers or channels, something might be done towards the greater safety of navigation. Something is, in fact, *called for*, on account of the various customs which prevail in certain districts; but a knowledge of them seems to be confined to the localities. And committees and others who have approached the question of collisions at sea, all seem to have neglected to give due prominence to the want of attention to that which is the root of evil,—namely, that when ships are approaching in opposite or oblique directions, no collision would be likely to take place *if one commander knew what the other was about to do with his helm.* Positive safety hinges on this.

So little however is this precious hint known or sought for in general, that, absolutely, a man-of-war steamer navigating the Thames, and meeting a river steamer, would use signs to her helmsman having *opposite significations* in each vessel; that is to say, for instance, the naval commander extending his hand to signify to his helmsman port, might be understood by the river steamer's rule to be about to starboard the helm. There is no rule of the road as enforced by law to prevent this: if any exists, the writer distinctly assures the public that it is not generally known, and even naval officers are left to their own judgment in this matter. And again, as if still further to complicate this serious question, a commander in each service will give his order by hand, according as he is fitted with a *wheel* or a *tiller*; for, as an example, motion of the hand generally indicates the direction in which motion is to be communicated to the part of the steering apparatus which is touched by the hand [STEERING APPARATUS], and the spokes of the wheel move in a direction contrary to that of the tiller. Without the aid, therefore, of some further legislation, can we hope to prevent collisions? It may, moreover, be remarked, that if two persons are meeting carelessly on a pavement, collision is only avoided by one of the two *knowing in proper time what the other is about to do.* The same remark applies to shipping: a ready means of knowing *in time* the intended motions of an opponent seems indispensable to safety. Some such rule, therefore, as the following is much wanted: When a commander (throughout the world, if possible), seeing another vessel approach, extends his right arm horizontally, let it signify to his own helmsman—starboard the helm; let the extension of his left arm signify to his own helmsman—port your helm. His opponent, seeing this, could act *on the moment*, and would know what to do accordingly. If in a steamer and about to stop her, let both his arms be held up while he gives the word. *Accidents by day could, under such simple rules, scarcely occur.*

In remarking upon the third assumption, that the rules of the road by night may be defective, we enter upon a wider field of inquiry; and although we purpose going somewhat fully into the question of lights at sea in its proper place in this work [Lights at Sea], we remark here how very plainly the tabular abstract given in a previous column shows, that if any system of lighting vessels under way did exist in 1856, that system required amendment. Some considerable improvement has indeed been made, after long and elaborate investigations, by the Board of Trade, through ship-masters, pilots, boatmen, &c., and evidence from all ports of Great Britain; yet we can show that great defects still mar the perfect working of the new regulations; and it is probable that the greater number of accidents by night from collision will still (as in 1856) abound on the parts of the coast which are best lighted, such as Dungeness, Beachy Head, the Start Point, &c.; for it is reasonable to suppose, that the more vessels congregate at those headlands, the more must the confusion of lights increase, as they are at present ordered to be used by sailing- *and* steam-vessels, each steamer having three and each sailing-vessel two lights. To distinguish a steamer from a sailing-vessel, the law wisely requires the steamer to carry a white light *on the mast*, *besides* the green and red lights, one on each side; while the sailing-vessel carries only the coloured lights, except when at anchor. Now, imagine a vessel suddenly entering a channel much frequented by steamers; every steam-vessel in sight will cause anxiety to every sailing or steam master, because the white light is seen all round, and the intensity of the various-coloured lights is so uncertain, especially in hazy weather, that a ship near at hand may exhibit coloured lights which are scarcely visible, while one more distant may show strong ones. Now, confusion and anxiety would, it is evident, be caused to a mariner mainly by the number of white lights indicating *steamers*, each of which lights would require scrutiny to ascertain its connection or otherwise with coloured lights of a vessel under way; but what is now proposed would completely remedy this.

The following improvements, exceedingly simple in themselves, and very easy to be adopted, are submitted as a perfect and unobjectionable night system :—

1. *Let a white light always be considered a danger light.*

2. Let steamers *and* sailing-vessels carry the screened coloured lights as at present; namely, green on the starboard side, red on the port side. But let these lights be placed abreast the foremast; at present they are often fixed upon the quarter, and consequently become shut in too soon.

3. Let all vessels, sailing or otherwise, when within soundings, carry also by night a white light.

4. Let steamers carry their white light at the mast, or *high* on the fore-stay; and sailing-vessels carry it at the bowsprit end, or somewhere *low* as convenient amidships.

5. Let all vessels at anchor carry a white light, showing all round, but not placed so high as to be mistaken for a steamer's: the absence of the coloured lights will always, as at present, show that it is only a vessel at anchor.

6. *Let all white lights of vessels under way be so fixed and screened as only to be seen within a space of two points on either bow;* and in case of a fast vessel overtaking a slower one, and in her wake, *let* all white lights of vessels under way be screened so as to be visible from abaft within one point of the line of keel astern. (This can easily be done.)

These precautions being adopted, no confusion can embarrass a master mariner, because on entering a port, if a hundred vessels be there under sail or steam, he, so far as regards danger of being run into, need only notice the white or danger lights; these being "shut in," and there being a good average and trusty look-out forward, confidence will not forsake a shipmaster or pilot, and the safety of his vessel will be in his own control; *at present it is not,* although the present system of shutting in a coloured light is good *so far as it goes.* In using, however, the danger light, some assistance can be given similar in effect to that produced by day, having for its object the power of immediately indicating and ascertaining *what each master is about to do.*

7. Let it therefore be a law that each commander or pilot has, between sunset and sunrise, always a hand-lantern ready lighted and standing on the paddle-box or near him, as most convenient; and being of one wick, having three faces (such are used on railways); the centre light being white, the left-hand one red, and the one on the right hand green. On seeing a danger-light near, if he intends to keep straight on, let him flash or swing his lantern with his white light towards his opponent's; if he is about to starboard his helm, let him exhibit his green light; if to port his helm, let him show his red light.

A few additional precautions or modifications may to some appear necessary; but the principle of a danger light is in our sea services necessary to the public safety; and while our object in giving to the public the actual state of the question is rather to *suggest* than to *dictate*, it is fully believed that, by attention to some such system as the above, collisions at sea may be rendered nearly impossible both by day and night, except from *culpable negligence.*

Another very important suggestion as to collisions at sea was published in the 'Nautical Magazine' in 1857. Mr. George Herbert, as already noticed under the word Buoys in this work, proposed to so arrange or dispose of the traffic in the English and St. George's Channels as to give to maritime commerce what in its nature approximates closely to a tram-road system. The smile of incredulity and doubt is too readily raised in nautical men, nor can we be astonished if the minds of those who were trained in the old sea school are as yet unprepared for the great changes which every day's experience render more than probable. But we must be guarded, and not encourage rooted prejudices on subjects which require all our wisdom and vigilance. It is scarcely a reproach to the present age, that the scheme of penny postage, the screw steamer, the electric telegraph, &c., met with distrust. In this instance it is enough for us (and with that impartiality which ought to influence statements of the present condition of arts and science) to record the beginnings of a change which may take years to perfect; to make known suggestions, which, if it be found possible to be carried out, may greatly facilitate the transit of passengers and merchandise through the most perilous parts of a sea voyage, and prevent collisions, fifty-eight of which occurred in the English Channel alone in the year 1856, eight being attended with total loss.

Mr. Herbert's proposition seems to be founded on a remarkably simple assumption; namely, that we almost never hear of a vessel running foul of the Eddystone Lighthouse. He proposes, therefore, to moor light-vessels of a peculiar form (a general sketch of which has been given under the word Buoys) in the English Channel, precisely in the generally received line of fairway, and to cause all ships and vessels bound down Channel to keep to the northward of this line, and all bound up Channel to navigate on the south side of this limit. To place light-vessels along this fairway line from Dungeness to just beyond the Scilly Islands, each light-vessel to be moored on the meridian of a degree of longitude. By this means the light-ships would in the latitude of the Channel be only about 38 miles apart, and each would be marked with a conspicuous number indicating its longitude. Vessels in the fairway track could never in fair weather be far out of sight of some one of those lights after sunset.

That some such plan as the above would be a boon to shipping can scarcely admit of a reasonable doubt; but when we remark, further, that Mr. Herbert's plan is extended to highly interesting details,—such as having a store of provisions and water at the westernmost light-ship, for the relief of those so frequently detained by adverse winds for several weeks, and to relieve whom, at present, the Admiralty are obliged occasionally to send ships of war; to have effective fog-signals at each light-vessel; to have a submarine telegraph to the westernmost light, in order that arrivals may be announced,—these, and various other ingenious and valuable suggestions, seem to be worthy of an impartial investigation by the Board of Trade. In the cause of humanity, as having reference only to the question of collision in the English and St. George's Channels, surely the endeavour to prevent accidents to life and property on so great a scale should not be impeded by merely speculative and perhaps visionary obstacles, and possibly by the unfounded disparagements which *novelties*, as such, too often evoke.

The responsibility of introducing some such scheme as the above would weigh lightly when placed in the balance with the responsibilities which far more heavily attach to supineness and indifference.

COLOCYNTH, or as it is called on the Continent, coloquintida, or bitter-apple, an annual plant. [Cucumis, in Nat. Hist. Div.] Referred in 'the London Pharmacopœia,' to the genus *Citrullus* (Schrad.), the fruit of which is about the size of, but rather lighter colour than, an orange; the rind smooth; when the rind has been removed, a white spongy pulp or pith is found within, which constitutes the officinal part, or the colocynth, the seeds being rejected. The rind is generally removed before reaching Europe, except the larger variety from Mogadore, used for exhibiting in show-bottles in druggists' windows. One hundred parts of decorticated apples consist of twenty-eight parts of pure pith, and seventy-two parts of seeds.

The active principle is a peculiar bitter principle (Colocynthin), which is of a resinoid nature, more soluble in alcohol than water; its solubility in water is much increased by union with extractive, combined with which it exists in the pulp, so that nearly all the virtues are yielded to a watery extract, which is generally employed for its administration. The compound extract, in the formation of which proof spirit is used, and to which are added other purgative substances and aromatics, is, however, preferable, and it is thereby rendered milder yet more certain in its action.

It is a purgative in very constant use, either alone, or more commonly united with mercurial purgatives: it is employed for the removal of constipation and visceral obstructions; at the commencement of fevers and other inflammatory complaints it is of decided utility. As an overdose has all the poisonous effect of a vegetable acrid, it must be used with caution.

COLOMBIC ACID ($C_{42}H_{22}O_{12}$?). An acid, little known, contained in colombo root (*Cocculus palmatus*).

COLOMBIN ($C_{42}H_{22}O_{14}$?). The active principle of the colombo root. It is neutral, crystalline, and only slightly soluble in cold water, alcohol, or ether.

COLONEL, the commander of a regiment or battalion of troops; he is the highest in rank of those called field officers, and is immediately subordinate to a general of division.

The derivation of the word is uncertain. It is supposed to have been given originally to the leader of a body of men appointed to found a colony; or to have come from the word *coronarius*, indicating the ceremony of investing an officer with the command of a corps; or, finally, from the word *columna*, denoting the strength or support of an army.

The title of colonel-general was, for the first time, conferred by Francis I., about the year 1545, on officers commanding considerable divisions of French troops, though, according to Brantome, it had been given to the chief of an Albanian corps in the service of France at an earlier period. When the troops of that country were formed into regiments (the infantry about 1565, and the cavalry seventy years afterwards), the chiefs of those corps were designated *Mestres de Camp;* and it was not till 1661, when Louis XIV. suppressed the office of colonel-general of infantry, that the commanders of regiments had the title of colonel.

In England, the constitution of the army was formed chiefly on the model of the French military force; and the terms regiment and colonel-general were introduced into this country during the reign of Elizabeth. It must, moreover, be observed, that in the regulations made by the citizens of London for forming the militia in 1585, it is proposed to appoint *colonels* having authority over ten captains; and that both colonels and lieutenant-colonels are distinctly mentioned in the account of the army which was raised in order to oppose the threatened invasion of the country in 1588. Before the time of Elizabeth, it appears that the commanders of bodies of troops equivalent to regiments had only the general title of captain.

The duties of colonels formerly are described in Ward's 'Animadversions of Warre,' which was published in 1639. The colonelcy of a regiment is now an honorary title carrying a certain emolument with it. See 'Hart's Army List.' The colonels of regiments have little or nothing to do with the actual command of the regiment, but are generally general officers, who receive the colonelcy of a regiment either by seniority or for distinguished service. The emolument above referred to was derived formerly from the colonels providing the clothing of a regiment, and being allowed the difference between the price at which the contractor furnished the clothing and the sum allowed by government. This has now been changed to a fixed emolument, and the clothes are provided by government. Colonels take precedence of one another according to the dates of their commissions, and not according to the seniority of their regiments.

The lieutenant-colonel is in rank immediately under the full colonel. He has the whole command of the regiment, and is responsible for the drill and discipline.

The annual pay of a colonel is, in the Life Guards, 1800*l.*; in the Grenadier Guards, 1200*l.*; in the Coldstream and Scots Fusilier Guards, 1000*l.*; in the 1st Dragoon Guards, 1000*l.*; in the cavalry regiments generally, 900*l.*; and in the regular infantry, 500*l.* The daily pay of a lieutenant-colonel is, in the Life Guards, 1*l.* 9*s.* 2*d.*; in the Foot Guards, 1*l.* 6*s.* 9*d.*; and in the infantry, 17*s.* The price of a lieutenant-colonel's commission is, in the Foot Guards, 9000*l.*; in the Life and Horse Guards, 7250*l.*; in the Dragoons, 6175*l.*; and in the infantry of the line, 4500*l.* For further particulars of rates of pay, &c., see 'Hart's Army List,' pay tables.

COLONNADE, a general term for any range of columns supporting an architrave. The term peristyle is often applied in the same sense, yet somewhat inaccurately, since it denotes a range of columns continued quite round a building or court, as in a peripteral temple, the Town Hall at Birmingham, or the Bourse at Paris. The covered way at the Quadrant, Regent Street, was a good example of a colonnade; the most familiar existing examples are the colonnade at the Italian Opera House in the Haymarket, and the columned front of the British Museum.

CO'LONY (in Latin *colonia*, a word derived from the verb *colo*, *colere*, to till or cultivate the ground) originally signified a number of people transferred from one country or place to another, where lands were allotted to them. The people themselves were called Coloni, a word corresponding to our term colonists. The meaning of the word was extended to signify the country or place where colonists settled, and is now often applied to any settlement or land possessed by a sovereign state upon foreign soil. Thus Ceylon and the Mauritius are called British colonies, though they are not colonised by Englishmen, the former being inhabited by natives, and the second by French or descendants of French colonists. The proper notion of the word "colony" (as determined by the general use of the term) seems to be a tract of land, either wholly or partly colonised, that is to say, possessed and cultivated by natives, or the descendants of natives, of another country, and standing in some sort of political connection with and subordination to that country, which is then called the mother country.

The formation of colonies is among the oldest occurrences recorded in history or handed down by tradition. Maritime states, such as those of Phœnicia and of Greece, possessing only a scanty territory, would naturally have recourse to emigration as their population increased. In both these countries the sea afforded a facility for transferring a part of their superabundant citizens, with their families and moveables, and their arms, to some foreign coast, either uninhabited or thinly peopled by less-civilised natives, who, by good will or by force, gave up to them a portion of their land. The emigration might be voluntary or forced; it was no doubt in many cases the result of civil contentions or foreign conquest, by which the losing party were either driven away, or preferred seeking a new country to remaining at home. The report of some remote fertile coast abounding in valuable productions would decide others. Lastly, the state itself having discovered, by means of its merchants and mariners, some country to which they could trade with advantage, might determine upon sending out a party of settlers, and might establish a factory there for the purpose of sale or exchange. In fact, commercial enterprise seems to have led both to maritime discovery and to colonisation as much as any one single cause. Such seem to have been the causes of the numerous Phœnician colonies which, at a very early date, were planted along the coasts of the Mediterranean. Tyre itself was a colony of Sidon, according to the Old Testament, which calls it the "daughter of Sidon." Leptis Magna, near the great Syrtis, was also a colony of Sidon, according to Sallust ('Jugurth." c. 78). Hippo, Hadrumetum, Utica, and Tunis, were Phœnician colonies, and all of greater antiquity than Carthage. The Phœnician colonies extended along the north coast of Africa as far as the Pillars of Hercules (the Straits), and along the opposite coast of Spain, as well as on the Balearic islands, and Sardinia and Sicily. Those on the Spanish coast seem to have been at first small settlements or factories for the purpose of trade between the metropolis or mother country and the natives. Several of them, however, such as Gades, by degrees took the trade into their own hands, and became independent of the mother country. The foundation of Carthage was an instance of another kind. It resulted, according to tradition, from an emigration occasioned by the tyranny of a king of Tyre. There is another confused tradition of a Phœnician or Canaanite emigration to Mauritania, occasioned by the conquest of Palestine by Joshua, and mentioned by Procopius and Suidas, as well as by some Jewish commentators. [BERBERS, GEOG. DIV.] The Phœnicians very early settled in the fertile island of Cyprus, which lay opposite their own coast. Of their settlements in the islands of the Ægean Sea we have only traditions referring to times previous to the war of Troy, and mentioned by Herodotus, and after him by Thucydides, who says that the Phœnicians and the Carians inhabited most of the islands, and carried on piracy, until Minos, king of Crete, drove them away, and planted new colonies. Herodotus says they had once a settlement in the island of Thasus, where they worked the gold mines. They also had a settlement on the island of Cythera (Cerigo), which lay conveniently for their trade with the Peloponnesus. Thucydides (vi. 2, &c.) also mentions that the Phœnicians formed establishments on the promontories and small islands on the coast of Sicily, from which they traded with the native Siculi; but that when the Greeks came to settle in great numbers in that island, the Phœnicians abandoned several of their posts, and concentrated themselves at Motya, Soloeis, and Panormus, now Palermo (which last probably had then another name), near the district occupied by the Elymi or Phrygian colonists (who had emigrated from Asia after the fall of Troy, and had built Entella and Egesta), trusting to the friendship of the latter, and also to their proximity by sea to their countrymen of Carthage. These three Phœnician settlements, however, merged afterwards into Carthaginian dependencies. The Phœnicians appear also to have occupied Melita or Malta, and the Lipari islands, one of which retained the name of Phœnicusa. Of the Phœnician settlements in the south part of Sardinia we have the report of Diodorus (v.) and a fragment of Cicero pro Scauro, published by Mai. The Phœnicians and Libyans are said to have been the earliest settlers in Sardinia, and to have founded Caralis (Cagliari) and Sulci. A Phœnician inscription was found in a vineyard at Cape Pula, belonging to the monks of the order of Mercy, and was explained by De Rossi, 'Effemeridi Letterarie di Roma,' 1774. But the undoubted field of Phœnician colonisation was the north coast of Africa. There the Phœnician settlements seem to have been independent, both of the mother country and of each other. We have the instance of Utica and Tunes, which continued separate communities even after Carthage had attained its great power; Carthage only exercising the hegemony or supremacy. This seems to have been the case among the original Phœnician towns; Sidon, Tyre, Aradus, &c., each a distinct commonwealth, forming a sort of federation, at the head of which was the principal city, at first Sidon, and afterwards Tyre. A feeling of mutual regard seems to have prevailed to the last between the various Phœnician towns and colonies, including Carthage, as members of one common family.

The colonies established afterwards by the Carthaginians in the interior as well as on the coast of Africa, Sicily, and Spain, were upon a different plan from those of the Phœnicians: they were made through conquest and for the purpose of keeping the country in subjection, like those of the ROMANS [CARTHAGE, GEOG. DIV.], with the remarkable exception of the emigration colonies taken by Hanno to the west coast of Africa.

The earlier Greek colonies appear to have owed their origin to the same causes, and to have been founded upon the same plan as those of the Phœnicians. Thucydides (i.) says, that "after the Trojan war, and the subsequent conquest of Peloponnesus by the Dorians, Greece being restored to tranquillity, began to send out colonies. The Athenians, whose country was overflowing with people from other parts of Greece, who had flocked thither for security, began to send out colonies into Ionia and to many of the islands; the Peloponnesians sent theirs to Italy, Sicily, and some parts of Greece. But all these colonies were sent after the Trojan war." The Dorians from Megaris, Argos, Corinth, and other places, colonised some of the larger islands, part of Creta, Rhodes, Corcyra, as well as Ægina, Cos, &c. They founded the Hexapolis on the south-west coast of Caria, in Asia Minor, which district took from them the name of Doris. A colony of Lacedæmonians founded Cyrene. The Megarians founded Chalcedon, Byzantium, Selymbria, Heraclea, and other places on the coasts of the Euxine. Sicily also was chiefly colonised by Dorians. Syracuse was a Corinthian colony, which afterwards founded Acræ, Camarina, &c., Gela was a colony of Rhodians and Cretans, and Agrigentum was a colony from Gela. The Megarians founded Selinus. The Chalcidians built Naxus, which was the first Greek settlement in Sicily, and afterwards took Leontini and Catana from the Siculi. For a more detailed account of the numerous Dorian colonies, see K. O. Müller's 'History of the Doric Race.'

The Ionians from Attica, another great branch of the Hellenic stock, after the death of Codrus, the last king of Athens, emigrated to the west coast of Asia Minor, which took its name from them and established there twelve cities or communities, which quickly rose to a high degree of prosperity, and formed a kind of federal union. About eighty years before, the Æolians and Achæans, two nearly allied races, being driven away from Peloponnesus by the Dorians, had emigrated to the coast of Asia Minor, where they formed colonies from Cyzicus on the Propontis as far southwards as the Hermus. Phocæa was the most northern of the Ionian towns on the borders of Æolis. The Æolians also colonised the islands of Lesbos, Tenedos, and others in that part of the Ægean. These emigrations were posterior to the time of Homer, who mentions other people as occupying that coast. The Athenians at a later date colonised Eubœa, where they founded Chalcis and Eretria, and they also sent colonies to Naxos, to the islands of Ceos, Siphnos, Seriphos, and other islands of the Ægean. Many of these colonies having thriven and increased, became colonisers in their turn. The enterprising mariners of Phocæa formed various colonies, the most celebrated of which is Massilia on the south coast of Gaul. The Chalcidians of Eubœa founded Cumæ, on the west coast of Italy, in the country of the Opici. Pirates from Cumæ founded Zancle, but a fresh colony of Samians and other Ionians escaping from the Persian invasion, in the time of the first Darius, took Zancle, and were afterwards in their turn dispossessed by Anaxilas, tyrant of Rhegium, who called the town Messene (now Messina), from the name of his original country in the Peloponnesus. The Æolians founded Dicæarchia, afterwards Puteoli, and they with the Cumæans are believed to have founded Parthenope (Naples). Ionian colonists settled on the coast of Sardinia.

The Greek colonies on the east coast of Italy, setting aside the confused traditions of Arcadian immigrations, Pelasgian, &c., supposed to have taken place before the Trojan war, consisted chiefly of Dorians and Achæans from the Peloponnesus. Croton, Sybaris, and Pandosia were colonies of the latter. Tarentum was a colony of Lacedæmonians, and Locri Epizephyrii of the Locrians. Greek colonies were settled both on the north and east sides of the Pontus (Black Sea), and also on the north coast in the modern Crimea. [BOSPORUS, in GEOG. DIV.]

As to the relations subsisting between the colonists and the natives or prior inhabitants of the countries which they occupied, it was undoubtedly in most cases strictly in accordance with the right of the strongest. Either the natives withdrew into the interior and left the ground to the new occupants, as the Siculi did in several instances, or they resisted, in which case, when overpowered, the men were exterminated or reduced to slavery, and the conquerors kept the women for themselves. In some instances the older inhabitants were reduced to the condition of serfs or bondmen to the new settlers. The records of authentic history do not present us with an instance of any colony being settled in a country where there were not previous inhabitants. The consequence of the immigration of a new race, who seek to possess themselves of the land, must be the extermination or gradual decay of the prior race, unless the old inhabitants are made slaves. So far as we trace the history of Greek colonies in the scattered fragments of antiquity, such were the consequences of their colonial settlements. On the coast of Italy it would appear that the Greeks pursued a more humane or more politic course. They are said to have allied themselves to and intermarried with the natives, and by their superior civilisation to have acquired great influence. It may here be remarked that the Greeks, so far from being averse to foreign intermixtures, as some have said, mingled their blood freely with that of all the nations with whom they came into contact, and thus the civilisation of the Hellenic stock was gradually introduced among nations less advanced in the useful arts.

What were the relations between these Greek colonies and the mother country, and between those colonies that were of a kindred race?

This may be gathered pretty clearly from Thucydides. Epidamnus was a colony of Corcyra; but the leader of the colony (*οἰκιστής*), the founder of the colony, or the person under whose conduct it was settled, was a Corinthian, who was called or invited, says Thucydides, from the mother city (called by the Greeks the metropolis, *μητρόπολις*, or parent state), according to an ancient usage. Thus it appears that if a colony wished to send out a new colony, this was properly done with the sanction of the metropolis. Some Corinthians and other Dorians joined in the settlement of Epidamnus, which became a thriving community, and governed itself independently of both mother countries. In the course of time, however, civil dissensions and attacks from the neighbouring barbarians induced the Epidamnians to apply to Corcyra, as their metropolis, for assistance, but their prayers were not attended to. Being hard pressed by the enemy, they turned themselves to the Corinthians, and gave up their town to them, as being the real founders of the colony, in order to save themselves from destruction. The Corinthians accepted the surrender, and sent a fresh colony to Epidamnus, giving notice that all the new settlers should be on an equal footing with the old settlers: those who did not choose to leave home were allowed to have an equal interest in the colony with those who went out, by paying down a sum of money, which appears to have been the price of allotments of land. Those who went out gave their services; those who stayed at home gave their money. "Those who went out," says Thucydides, "were many, and those who paid down their money were also many." For the moneyed people it was in fact an affair of pure speculation. The Corcyræans, themselves originally a colony from Corinth, having become very powerful by sea, slighted their metropolis, and "did not pay to the Corinthians the customary honours and deference in the public solemnities and sacrifices, as the other colonies were wont to pay to the mother country." They accordingly took offence at the Corinthians accepting the surrender of Epidamnus, and the result was a war between Corcyra and Corinth. (i. 24.)

Again, the Corcyræan deputies, who were sent to court the alliance of the Athenians against Corinth, stated, in answer to the objection that they were a colony of Corinth, that "a colony ought to respect the mother country as long as the latter deals justly and kindly by it; but if the colony be injured and wrongly used by the mother country, then the tie is broken, and they become alienated from each other, because, said the Corcyræans, colonists are not sent out as subjects, but as free men having equal rights with those who remain at home." (i. 34.) This shows the kind of relation as understood by the Greeks between the metropolis and its colonies. The colonies were in fact sovereign states, attached to the mother country by ties of sympathy and common descent, so long as those feelings were fostered by mutual good-will, but no further. The Athenians, it is true, in the height of their power, exacted money from their own colonies as well as from the colonies of other people, and punished severely those who swerved from their alliance, such as Naxos; but this was not in consequence of any original right of dominion as supposed to belong to the mother country over the colony. Many of the colonies, especially the earlier ones, which were the consequence of civil war or foreign invasion, were formed by large parties of men under some bold leader, without any formal consent being asked from the rest of the community: they took their families, their arms, and their moveables with them, to conquer a new country for themselves; they left their native soil for ever, and carried with them no obligations or ties. Those that went off in more peaceful times, by a common understanding of the whole commonwealth, went also away for ever, and freely and voluntarily, though under a leader appointed by the parent state, to seek a country where they could find an easier subsistence than at home. In either case it was a complete separation of a member from the body. When the Athenians, in later times, took possession of parts of Eubœa (Thucyd. i. 114), and of Ægina (ii. 27), of Melos (v. 116), and shared the lands among their own citizens who went there, the relationship thus formed was of a different kind. In the case of Ægina the whole population, which was of Hellenic stock, was turned out, and a body of Athenians occupied their place, with the express object of being as a body or community subordinate to the state of Attica, in order to prevent the annoyance to which Attica had long been subject by the proximity of an independent island so well situated both for the purpose of annoying Attica and for self-defence.

That the colonies of a kindred race should feel a common interest in opposition to those of a rival branch is natural, and is proved among other instances by the case of the deputies from Egesta in Sicily, who, while requesting the assistance of the Athenians against the Syracusans and Selinuntians, urged as an additional plea that the Leontines, who were originally Chalcidians, and therefore akin to the Athenians, had been expelled from their town by the Syracusans, and showing that it was the interest of the Athenians to assist a kindred people against the prevailing power of the Dorian colonies in Sicily. (Thucyd. vi.)

Before we pass to the Roman colonies, we must say something of the system of colonisation among the other inhabitants of the Italian peninsula in the ante-Roman times. The Etruscans extended their conquests north of the Apennines in the great plain of the Po, and founded there twelve colonies, the principal of which was Felsina (Bologna). They afterwards, having defeated the Umbrians, many years before the assumed foundation of Rome, extended themselves into East and South Italy, penetrated into Latium, and took Campania from the Oscans, where they founded likewise twelve colonies, the principal of which was Capua. The Etruscans, being skilled in architecture, surrounded their towns with solid walls built of massive stones without any cement; they were also well versed in agriculture and hydraulics, and several of the earliest drains and canals in the Delta of the Po are attributed to them. They subjected, but at the same time necessarily civilised, the people among whom they settled. Their colonies seem to have formed independent communities, though allied by a kind of federation. The Etruscans also founded colonies in the Picenum, such as Hatria [ATRI, in GEOG. DIV.], and Cupra Montana and Cupra Maritima. They took from the Ligures the country around the gulf now called Della Spezia, and founded the city of Luna. They likewise sent colonies to the islands of Elba and Corsica, for the Etruscans were a commercial as well as an agricultural people; they navigated the sea, and in the sixth century before Christ they defeated the Phocæans, and drove them out of Corsica. The Etruscans civilised Italy by means of their colonies; but, unlike Rome, they did not keep them united under a central power.

The Sabini, an agricultural and pastoral people, living in a mountainous country, sent colonies in very remote times to other parts of Italy. It was their custom, after the lapse of a certain number of years, to celebrate solemn sacrifices in the spring season, and to consecrate to the gods a number of young men, who were to quit their native land, and proceed under the auspices of Heaven to seek a new country. In this manner the Piceni and the Samnites are said to have been colonies of the Sabini. The Samnites in their turn sent out other colonies, and the Lucanians were one of these. The Samnites as well as the Sabini were entirely given to agricultural pursuits.

Rome, in the earliest ages of the republic, adopted the system of sending out colonies to the conquered countries. But the Roman colonies were different from those of most other people, inasmuch as they remained strictly subject to the mother country, whose authority they were the means of enforcing upon the conquered nations. They were, in fact, like so many garrisons or outposts of Rome. Servius (Æn. i. 12) gives the following definitions of a colony, taken from much older authorities: "A colony is a society of men led in one body to a fixed place, furnished with dwellings given to them under certain conditions and regulations." Again, "Colonia is so called a colendo; it consists of a portion of citizens or confederates sent out to form a community elsewhere by a decree of their state, or with the general consent of the people from whom they are departed. Those who leave without such a consent, but in consequence of civil dissensions, are not colonies." The notion of a Roman colony seems to be this: the colonists occupied a city already existing; and this, with perhaps one exception or two, was the general character of the Roman colonies in Italy Proper. When the Romans afterwards extended their conquests into countries where there were no regular towns, or where the population being fierce and hostile, the Roman settlers must be ever on their guard against them, they built new towns in some favourable position. Such was the case in several parts of Gaul, Germany, Dacia, &c. But the Roman colonies in Italy consisted of Roman citizens, who were sent as settlers to fortified towns taken in war, with land assigned to them at the rate of two jugera of arable land or plantation for each man, besides the right of pasture on the public or common land. The old inhabitants were not ejected, or dispossessed of all their property; the general rule was, that one-third of the territory of the town was confiscated and distributed among the colonists, and the rest was left to the former owners, probably subject to some charges in the shape of taxes or services. The colonists constituted the *populus* of the place; they alone enjoyed political rights and managed all public offices, the old inhabitants being considered as the plebs. The ownership of the publicum or public property, including the pasture land, was probably also vested in the new settlers. It is natural to suppose that for some generations at least, no great sympathy existed between the old and the new inhabitants, and hence we frequently hear of revolts of the colonies, which means, not of the colonists against the mother city, but of the old inhabitants, who rose upon and expelled the colonists. But these events generally ended by a second conquest of the place by Roman troops, when the old inhabitants were either put to the sword or sold as slaves, or, under more favourable circumstances, lost at least another third of their property. In later times, during the civil wars of Rome, new colonies were sent by the prevailing party to occupy the place of the former ones; and the older colonists were then dispossessed of their property, either wholly or in part, just as they had dispossessed the original inhabitants. Hence the saying, "Veteres migrate coloni." Sometimes colonies, especially at a great distance from Rome, having dwindled away, or being in danger from the neighbouring populations, asked for a reinforcement, when a fresh colony was sent, to whom the old colonists gave up one-third of their property. Each of the older colonies, it is observed by Gellius (xvi. 13), was a Rome in miniature; it had its senators called Decuriones, its Duumviri, Ædiles, Censores, Sacerdotes, Augurs, &c.

A distinction must here be made between the Roman colonies and the Latin colonies. The former had all or nearly all the rights of the citizens of Rome, although Sigonius and some others pretend that they had not the jus suffragii; and yet, in various passages of Livy and others, colonists are styled cives and Romæ censi. The Latin colonies had not the jus Quiritium, but only the jus Latii. All those, however, who filled magistrates' offices in Latin colonies became Roman citizens. Such was the case with Tibur, Præneste, &c. The towns of Transpadane Gaul, as a reward for their fidelity to Rome, obtained the rank of Latin colonies without any colonists being sent to them.

There were also military colonies, which consisted of soldiers, to whom land was given instead of pay and provisions, as a resting-place after their campaigns. Sulla appears to have been the founder of these, and Cæsar and Augustus added greatly to their number. These colonies are distinguished by having military ensigns on their coins, while the Coloniæ Togatæ, or citizen colonies, have a plough on theirs. (Heinecc. 'Antiqu. Roman. Syntagma.') The coins of some colonies have both marks, which means that the original colony consisted of citizens, after which a second was sent, composed of military. In Tacitus ('Annal.' i.) the veterans complain that, after their long service, they were rewarded only with uncultivated lands, situated in the neighbourhood of the enemies of the empire.

The system of colonies adopted by Rome had a double political object,—to secure the conquered countries, and to satisfy in part the claims of its own poorer citizens, and to get rid of turbulent characters. The importance of the Roman colonies to the empire is well expressed by Cicero, who calls them "propugnacula imperii et specula populi Romani." Such they doubtless were, and at the same time they were the germ of the civilisation of Northern and Western Europe. A nation of civilised conquerors, whatever evils it may inflict to gratify its own cupidity, confers on the conquered people unintentionally still greater benefits. By their colonies in Spain, Gaul, on the banks of the Rhine, and in Britain, the Romans established their language and their system of administration. The imprint of their empire is indelibly fixed on the existing nations of Europe.

The difference between Colonia and Municipium is, that the latter was a town of which the inhabitants, being friendly to Rome, were left in undisturbed possession of their property and their local laws and political rights, and obtained moreover the Roman citizenship, either with or without the right of suffrage; for there were several descriptions of Municipia. [MUNICIPIUM.] The colonies, on the contrary, were all governed according to the Roman laws. The municipia were foreign limbs engrafted on the Roman stock, while the colonies were branches of that stock transported to a foreign soil.

Under the later Roman emperors, the difference between colonia and municipia became obliterated, and all were governed alike according to the Roman law, and a uniform system of administration. Augustus gave the right of Roman citizenship to all Italy. Antoninus Caracalla bestowed it upon all freemen, subjects of the empire. (For the Roman colonies, see Niebuhr, vol. ii.; Manutius, 'de Civitate Romana;' Sigonius, 'de Ant. Jure Ital.;' Heineccius, 'Syntagma,' &c.)

The northern tribes who overthrew the western empire did not found colonies; they overran or conquered whole provinces, and established new states and kingdoms. The same may be said of the Saracen conquests in Asia and Africa. But, after a lapse of several centuries, when Europe had resumed a more settled form, the system of colonisation was revived by three maritime Italian republics, Pisa, Genoa, and Venice. Their first settlements on the coasts of the Levant and Egypt were mercantile factories, which the insecurity of the country soon induced them to convert into forts with garrisons,—in short, into real colonies. The Genoese established colonies at Famagosta in Cyprus; at Pera and Galata, opposite to Constantinople; at Caffa in the Crimea, founded in 1266. They also acquired possession of a considerable extent of coast in that peninsula, forming a district subject to Genoa under the name of Gazaria. Another tract, on the coast of Little Tartary, called Gozia, was also subject to the Genoese, who had then the colony of Cembalo. In the Palus Mæotis they had the colony of La Tana, now Azof. On the south coast of the Euxine they possessed Samastro or Amastri. They had also a factory with franchises and their own magistrates at Trebizond, as well as at Sebastopolis. These colonies were governed by consuls sent from Genoa, and the order and justice of their administration have been much extolled. In the archives of St. George, at Genoa, there is a valuable unpublished manuscript containing the whole colonial legislation of the Genoese in the middle ages.

The Pisans, having taken Sardinia from the Moors, sent colonies to Cagliari and other places. Their settlements in the Levant were mere commercial factories.

The Venetians established colonies in the Ionian Islands, Candia, and Cyprus. Their system resembled that of Rome: they ruled, by means of their colonies and garrisons, over the people of those islands, whom they left in possession of their municipal laws and franchises. These were not like the settlements of the Genoese, merely commercial establishments—they were for conquest and dominion; in fact, Candia and Cyprus were styled kingdoms subject to the republic. The Venetians had also at one time factories and garrisons on various points of the coasts of the Levant, but they lost them in the Morea, Eubœa, Syria, and the Euxine, either through the Genoese, or afterwards by the arms of the Ottomans. We can hardly number among their colonies the few strongholds they once possessed on the coast of Albania, such as Butrinto, Prevesa, Parga, &c., any more than those possessed by the Spaniards and Portuguese on the coast of Barbary, Oran, Melilla, Ceuta, &c. They were merely forts with small garrisons, with no land attached to them. The name used in the Mediterranean for such places is presidii, and they are often used as prisons for criminals.

The discovery of America produced a great change in the system of colonisation. Hitherto, whether the colony had been planted by force or by treaty, the colonists on the whole were not greatly advanced in civilisation beyond the original possessors; and whether they reduced them to subjection or amalgamated with them, there was no essential difference of race; for even the early colonies of the Portuguese in Africa were either at places inhabited by the civilised Arabs, or in spots where they merely planted a military garrison to defend their trade. The Spaniards were the first who established colonies in America, and they were rapidly followed by nearly every European nation. But among these nations there was a great variety in the manner of the acquisition, the objects sought to be attained, and the mode of government in the colonies, both locally and with reference to that of the mother country. It soon became evident that not all nations were equally qualified to become successful colonists; to be so appears to require in the colonists, capital, superior knowledge and intelligence, industry, and firm resolution. The Spaniards, landing among the semi-civilised nations of South America, possessed the superior intelligence and the unconquerable resolution. They succeeded in subduing the natives; but they brought no capital, and they evinced no industry. From the beginning, they sought only to enrich themselves and their country by despoiling the natives, and by forcing them to work, while the commerce of the settlement was obstructed by burdensome and injurious restrictions. The consequence has been that the population, becoming a mixed one, treated as inferiors by the new Spanish accessions, and feeling their own strength, have thrown off their allegiance.

An essential qualification of a colony is that it should have and cultivate land, and consist at least in part of civilians. When a colony is sent to a country occupied by a few hunting tribes, as was the case in part of North-America at the time the English settled there, and as was also the case in Australia, the taking possession of part of the land for the purpose of cultivation is attended with the least possible injury to the aborigines, while, at the same time, it has in its favour the extension of civilisation upon a new shore. The savages generally recede before civilised man; a few of them adopt civilisation, and the rest become gradually extinct. When the limits are confined, the progress towards extinction is exceedingly rapid. The aborigines of Van Diemen's Land are now reduced to a very small number. This, however melancholy in one point of view, has been from the earliest times the great law of the progress of the human race. But the case is much altered when the natives are partly civilised, live in domestic societies, have settled habitations, and either cultivate the land or feed their flocks upon it. The colonists in such case do what the Romans did in their colonies; they take part of the arable land, or the whole of the common or pasture land, and leave to the natives just what they please, and if the latter resist, they kill them. Whether this be justice every man may ask himself. The case may be one of greater or less oppression, according as the land is either enclosed and cultivated, or merely used for pasture or the chace, and according as the natives are more or less numerous in proportion to the land, colonisation may proceed on a milder or harsher system. Still the question of justice remains the same, unless the natives be willing to part with their land by amicable arrangement. This system of purchase from the natives has been practised both by the English and Anglo-Americans in North America; but though it has the specious name of bargain, it has often been nothing more than a fraud, or sale under compulsion. The man of Europe has been long accustomed to regard the possession of the soil as that which binds him to a place, and gives him the most secure and least doubtful kind of property. His habits of accumulation, and of transmitting to his children a permanent possession, make him covet the acquisition of land. In whatever country he has set his foot, and once got a dominion in the soil, neither contracts, nor mercy, nor feelings of humanity, nor the religion which he carries with him, have prevented him from seizing on the lands of the owners, and punishing their resistance with death.

When the Portuguese first began their voyages of discovery in the 15th century, they took possession of some islands or points on the coasts of Africa and of India, and left there a few soldiers or sailors under a military commander, who built a fort to protect the trade with the natives, and afterwards also to keep those natives under a sort of subjection. In Brazil, settling among a people who were less advanced in civilisation than the Mexicans and Peruvians, and inhabited a country less densely populated, they effected their colonisation somewhat more peacefully, and maintained their empire with much less harshness. Brazil having no gold or silver (or none of much value), and the diamond mines occupying but a small space, the forced labour when employed was chiefly agricultural, and therefore less injurious. The agriculture produced commerce, and these united brought a considerable number of settlers; but the commerce was of a restrictive character, and the native Portuguese were a privileged class. The natives, to a considerable extent, remained roving and independent; the colonial population, confined to a few ports and the surrounding districts, where sugar, coffee, tobacco, and a few other products are grown, became discontented; and had not the political circumstances of Europe compelled the royal family of Portugal to retire to Brazil, it is probable the colony would have revolted. By that step, however, the colony became an empire; the misgovernment by foreigners ceased, a more enlightened system of commerce was adopted, and it has since grown rapidly in wealth and importance: but it has ceased to be a colony of Portugal.

The Dutch, with far higher qualifications for colonising than the Spaniards, followed almost a like system in their conquests of the Cape of Good Hope, the Moluccas, and in Java; but their object was to increase and to monopolise their trade. To this purpose all their efforts were directed, and for a time they succeeded to a considerable extent, but they did not attempt to draw any direct revenue from their dependencies. Powerful rivalry, however, and the dissatisfaction occasioned by the restrictions, altogether deprived them of some of their best colonies, and lessened the value of the remainder.

The French colonised Canada, and on the whole in a humane manner. But though in their relations with the natives they were not very successful in establishing themselves, they made the colonies too much of military settlements, and the civil colonial population increased very slowly. They kept troops and they raised fortifications, and both proved useless when put to the test; Louisiana they bought of Spain, made little progress in it, and sold it to the United States.

The English colonies have been acquired in almost every possible variety of manner: by settlement, by conquest, by treaty, by exchange. The North American colonies were the consequence of emigration, either voluntary or produced by religious persecution and civil war at home. The Puritans went to New England, the Quakers to Pennsylvania, and the Cavaliers to Virginia. They formed communities under charters from the crown, and had local legislatures, but were still subject to the sovereignty of the mother country. The mother country sent its governors, and named, either directly or indirectly, the civil functionaries. The precise amount of obedience that the colonies then owed to the mother country cannot be exactly defined. The American revolution only showed that it did not extend to a certain point, without showing how far it did extend. Australia was found almost a desert, and with the exception of a few incidental combats was peacefully settled. The Cape of Good Hope was taken from the Dutch; Jamaica and other West India islands from the Spaniards, French, and Dutch. The East Indies (which, however, is scarcely a colony, for until within the last few years Englishmen were not allowed to settle in it) has been obtained by treaty, by conquest, by succession, in an almost continued growth, without any violent desire for acquisitions, but from an impulse of self-preservation. The colonies have, as a general rule, local legislatures, elected by the people, and a governor and council named by the sovereign. The foreign commerce of these colonies is regulated by the sovereign authority of the mother country, and put on such a footing as generally to allow some of their products admission into British ports on more favourable terms than those of other countries. To the amount of this protecting duty, the colonies have the advantage of a partial monopoly in the markets of the mother country. The old strict colonial system, of excluding foreign countries from direct commercial intercourse with the colonies, had the double object in view of securing all the supposed advantages of the exchange of British for colonial products, and giving employment to the British merchant navy. The rigour of this system however has gradually relaxed, and given way to clearer views of self-interest. Still the colonial system, as maintained by Great Britain, presents in many instances examples of foreign possessions which are expensive to the country without any apparent corresponding advantages. The expenditure in most of the colonies for the purposes of administration and protection is beyond the means of the colonial revenues to meet, and the deficiency must of course be supplied by the parent state. That this is no trifle may be seen from the returns of the costs of the various British colonies for 1858. The total was 4,115,757*l.*, exclusive of the East Indies, and that was a less sum than in any of three previous years; and although a few may be considered rather as military or naval stations, yet the items show that none of the colonies are self-supporting, though many are large contributors to their own expenses. Gibraltar cost 423,589*l.*; Malta, 442,722*l.*; Cape of Good Hope, 682,015*l.*; Mauritius, 74,881*l.*; Bermuda, 158,061*l.*; St. Helena, 62,640*l.*; Heligoland, 1274*l.*; Ionian Islands, 199,470*l.*; Falkland Islands, 6523*l.*; and Hong-Kong, 303,735*l.*; the foregoing are all more or less military or naval stations. Of the Australian settlements, North Australia cost 5666*l.*; Western Australia, 94,769*l.*; South Australia, 9940*l.*; Victoria, 44,113*l.*; New South Wales, 59,646*l.*: Tasmania, 96,936*l.*; and New Zealand, 112,395*l.* Of the other plantations and settlements, Jamaica cost 193,711*l.*; Bahamas, 52,045*l.*; Honduras, 38,802*l.*; West Indies, 305,981*l.*; Canada, 286,484*l.*; Nova Scotia, 154,605*l.*; New Brunswick, 9430*l.*; Prince Edward's Island, 1500*l.*; Newfoundland, 20,114*l.*; Vancouver's Island, 210*l.*; West Coast of Africa, 126,039*l.*; Ceylon, 119,279*l.*; Labuan, 12,445*l.*: and sundry other colonies, 71,737*l.* The immense patronage which colonial possessions put at the disposal of the government is naturally one reason why colonies are looked upon as profitable things by those who participate in the advantages of posts and places in them. On the other hand, those who only contribute to these expenses may not unreasonably ask for some proof of solid advantage to the nation in return for this annual outlay. Setting aside the interests of those concerned in the administration of the colonies, it is asked, in many cases, what advantage does the rest of the nation receive? So far as colonies may be desirable posts for protecting British commerce and shipping, the advantage of maintaining them may be fully equivalent to the expense; and the settlement and protection of a colony by the natives of one country cannot fail to introduce the customs, the habits, and the wants of the country whence they come, which, consequently, will be in the best position for acquiring and maintaining possession of the commercial intercourse as it grows; this has been remarkably the case in regard to Canada, Australia, and the Cape. It is hardly possible to suppose that if they had been abandoned as too costly, the commerce would have assumed the vast importance which it has done. The protection of the mother country also gives a sense of security to intending emigrants, and the emigration is facilitated; it affords a most beneficial outlet to a superabundant population, removing a source of weakness and expense at home by the voluntary transfer of labour-power from where it has no value to a spot where it is of the greatest value; and, while it relieves the mother-country from a burden, it necessarily strengthens the bond of alliance, and contributes to the commercial prosperity of both parent and colony. Another prospective advantage is, the friendly relations that must necessarily exist from blood relationship, similarity of customs and feelings, and sameness of language, when the time arrives that the colony has grown powerful enough to maintain its own independence, and to assume the character of a state. Still, in every particular instance, the question as to the value of a modern colony to the mother country (omitting, as before mentioned, the value of the patronage to those who confer places in the colonies and the value of the places to those who receive them) is simply this: what advantage is this said colony to the productive classes of the country, and to those who consume the products of the colony? a question not always easy to answer; but this is the question, the solution of which must decide whether a colony ought to be maintained or not, if we look only to the interests of the mother country. If we look to the interests of the colony, it may be in many and certainly is in some cases, the interest of the colony to remain as it now is, under the protection and sovereign authority of the mother country. But again the question recurs, what is the advantage to the mother country? If some advantage cannot be shown, the maintenance of a useless colony is a pure act of national benevolence towards the colony and to those few of the mother country who have places in it. If our present relation with a colony such as Jamaica or Canada entails any expense on the mother country, we may ask whether all the commercial advantages that result from this relation would not be equally secured, if only the free commercial relation existed, and that of administration were to cease. In support of this view, it is shown that the commerce of Great Britain with the United States, now free and independent, has increased most wonderfully since the separation, and probably more rapidly than it would have increased under the colonial system. This being the case, a similar increase might be anticipated in the trade with all those foreign possessions whose trade is really of any importance. This argument, to which it is difficult to reply, is met by saying that if we give up those colonies that cause expenditure on the part of the mother country, some of them at least would be a prize for other nations, who would exclude us from the commerce of those former colonies, or allow it only on unfavourable terms; or that these colonies would throw themselves into the arms of foreign nations, and the same result would follow. To this it is replied, that no other nation is in a condition to take on itself the management of expensive colonies, especially when not in a condition to avail themselves to the fullest extent of the advantages of their commerce; nations, like individuals, will, if let alone, buy where they can buy cheapest, and sell where they can sell dearest. Spain, for instance, could derive no advantage from the possession of all Australia; she could draw no direct revenue from it; she could not use the colonial products, except the gold, which she could not buy, as she has no manufactures with which to effect the purchase.

The colonial administration of the British colonies is an important department of the general administration. At the head of it is the principal colonial secretary, who is one of the principal secretaries of state, assisted by two under secretaries.

A new feature was introduced into modern European colonisation, that of penal colonies, which was an extension of the principle of the presidii on the coast of Barbary, already mentioned. Convicts were sent by England first to North America, and afterwards to Australia and the Cape of Good Hope, by France to Guiana, by Portugal to the coast of Angola, by the Dutch to Batavia, and latterly by the French to Cayenne and to Lambessa in Africa. They were either employed at the public works or hired to settlers as servants, or were established in various places to cultivate a piece of land, for which they paid rent to the government. The policy of penal colonies has been much discussed. They may afford a relief at least temporary, but at a great cost to the mother country, by clearing it of a number of troublesome and dangerous characters, especially so long as criminal legislation and the system of prison discipline continue as imperfect as they are at present in most countries of Europe; but with regard to the convicts themselves, and the prospect of their reformation, everything must depend upon the regulations enforced in the colony by the local authorities. Although the system had its advantages as regarded the mother country, and perhaps as regarded the convict, yet the colonies as they increased in wealth and numbers, felt it to be an intolerable grievance to be continually flooded with the criminal refuse of the parent state. The system was opposed in the English colony at the Cape of Good Hope to the verge of an insurrection, but England gave way to the voice of justice, and on the remonstrances also of the Australian colonies, the system has been altogether abandoned, and only a few criminals are now sent to Western Australia, to Bermuda, and to Gibraltar, merely as to convict prisons, to be employed on public works.

We subjoin a list of the principal colonial possessions of the various European states; but of all the important ones accounts will be found under their proper heads in the Geog. Div.

The colonies of England consist of British North America, British West India Islands, with the Bahamas and Bermudas, and British Guiana in S. America; Sierra Leone, Cape Coast, and Cape of Good Hope in Africa; the islands of St. Helena, Mauritius, Ceylon, Prince of Wales Island, Singapore, and Malacca; various settlements on the coasts of Australia, and Tasmania, or Van Diemen's Land. The united population of the whole of these colonies is estimated at 7,148,000. The vast possessions of Great Britain in India, as we have already stated, are not to be considered as colonies, though they are dependencies; they contain a population of 180,367,148 persons. Gibraltar, Malta, and Heligoland, military stations, have a population of 146,591 persons.

France has the islands of Guadeloupe, St. Pierre, and Miguelon, and French Guiana in America; Senegal and Goree on the Coast of Africa; the island of Bourbon; Pondichery, in the East Indies, with two or three trifling dependencies; the Marquesas islands, New Caledonia, with Tahiti and Wallis islands, under protection, in the Pacific; and the important acquisition now being colonised to a considerable extent, of Algerie; the total has a population of 3,506,218, of which 2,880,383 are in Algerie, the European population in January, 1857, being 167,670.

Spain has lost her vast dominions in Mexico and South America, but has retained the fine islands of Cuba and Puerto Rico, and the Virgin islands in America; in Asia she has the Philippine islands; in Africa she has the Presidios and the Guinea islands, the old system still prevails; slave labour is employed; and the Spanish colonies are now perhaps the only ones that yield a direct revenue to the mother country; though it is probable that the United States makes a greater profit with them by its commerce, than Spain does by its taxation. The population of the whole of the colonial possessions is estimated at 4,528,633.

Portugal has lost the Brazils, but it has still numerous settlements on the coast of South and East Africa, at Angola, Benguela, Loango, and on the Mozambique; but these settlements are the most degenerated of all European colonies. In India the Portuguese retain Goa; they have a factory at Macao; and a settlement on the northern part of the island of Timor. The population is estimated at 2,756,379.

The Dutch have the islands of Curaçao and St. Eustache and Surinam in Guiana. In Asia they have the great colony of Batavia with its dependencies, various settlements on the coasts of Borneo, Sumatra, Celebes, Timor, and the Molucca islands. The population is estimated at 16,433,761.

The Danes are possessed of the islands of St. Cruz, St. John, and St. Thomas in the West Indies; and Christianburg, near Accra, on the Guinea coast; the population of the whole is only 37,187.

The Swedes have the island of St. Bartholomew in the West Indies; population about 18,000.

A society of North American philanthropists founded about 1821, on the Guinea coast, east of Cape Mesurado, a colony of emancipated negroes, who have been transferred thither from the United States. The colony is called Liberia. The total population, including natives, may be about 60,000.

COLOSSEUM. [Amphitheatre.]

COLOSSIANS, EPISTLE TO THE, a canonical epistle of the New Testament, addressed by St. Paul to the Christians of Colossæ, a city of Phrygia. The date generally assigned to this epistle by the commentators and critics is A.D. 62. ('Tablettes Chronologiques,' par l'Abbé Lenglet Dufresnoy, tome ii. p. 211. Dr. Adam Clarke's 'Succession of Sacred Literature,' vol. i. p. 89.) Some say A.D. 63, or the 9th of Nero. In the Dissertations on the Harmony of the Gospels, by the Rev. Mr. Greswell (vol. ii. pp. 63–36), it is shown that the Epistles to the Ephesians, to the Philippians, and to Philemon, were written by St. Paul at the same time as the one to the Colossians, namely, in A.D. 60, nearly at the termination of the apostle's first imprisonment at Rome; and Epaphroditus in Philemon is considered by Mr. Greswell to be the same person as Epaphras in Colossians. There is a great similarity between this epistle and that to the Ephesians, the one being a commentary on the other, as Michaelis observes. From the expressions in ch. i. ver. 4, 7, 9, and ch. ii. 1, where he says, "for as many as have not seen my face in the flesh," it is inferred by some that St. Paul himself was personally unknown to the Christians of Colossæ; for though he travelled twice to Phrygia, it appears from Acts, chs. xvi. and xviii., that he visited the northern parts, while Colossæ was in the southern part. Others, especially Dr.

N. Lardner (‘Credibility Gos.’), who argues on the statements of Theodoret (tom. iii. p. 342), assert that St. Paul preached and planted the church at this city. According to Eusebius, this city was one of three which, in the 10th year of Nero (that is, a year after the reception of this epistle), were totally destroyed by an earthquake. The chief object of St. Paul in this epistle appears to have been to exhort the Christians of Colosse to adhere stedfastly to the doctrines which he taught, and to reject the opinions of the Jews and the Pagan philosophers. The concluding sentence of the fourth chapter states that the conveyance of this address was committed to Tychicus and Onesimus. (Eichhorn, Michaelis, Horne.)

COLOUR (in Optics). [LIGHT.]

COLOUR (in Fine Arts). [PAINTING.]

COLOURING MATTERS. Each of the three great natural kingdoms, the animal, the vegetable, and the mineral, abound in substances the chief peculiarity of which is, that they possess colour. For the cause of this colour see the article LIGHT; COLOUR. At present it will only be necessary to mention these colouring matters, classify them, state their general properties, and direct attention to the source whence more detailed information may be derived concerning them individually.

Colouring matters are either *organic* or *inorganic*, that is derived from organised bodies, such as animals or vegetables, or from unorganised substances, namely minerals. Organic colouring matters are usually more complex in composition, and more liable to alter in tint than the inorganic ones; indeed the latter are for the most part definite compounds of metals, while the former are often mixtures of several proximate principles, and have always a tendency to be decomposed into more simple forms of matter.

In addition to the colours that occur ready formed in nature, the study of chemistry has brought to light many artificial ones.

The great point of interest connected with colouring matters is the employment of them in the decorative arts. Scarcely one can be mentioned, provided it can be obtained at anything like reasonable cost, and is possessed of beauty and durability, which has not been employed by the calico-printer, paper-stainer, painter, &c.

For the sake of convenience the following colouring matters will be treated of without reference to their organic or inorganic origin, but will be grouped together according to their similarity in appearance.

YELLOW COLOURING MATTERS.

Arnotto. [ARNOTTO; BIXIN; also BIXA, in NAT. HIST. DIV.]

Chrome-yellow occurs in twenty shades, and under as many different names, each celebrated for its particular tint; thus prefixed to the word yellow we find, *Altenburg, Cahlaer, Citron, Cologne, Gotha, Leipsic, Paris, Zwickau, &c.* [LEAD, *Chromate of.*]

Fustic or *yellow wood.* The wood of a tree. [FUSTIN; also RHUS COTINUS, in NAT. HIST. DIV.]

Gamboge. [GAMBOGE; also GARCINIA, in NAT. HIST. DIV.]

Ochre occurs native in various shades, and is met with under the names of *yellow ochre, gold yellow, gold earth, gold ochre, yellow sienna, Chinese yellow.* It is composed of hydrated oxide of iron with alumina, lime, &c. [OCHRE.]

Orpiment, auripigmentum, Persian or *king's yellow.* [ARSENIC, *Sulphide of.*]

Persian berries, or *Avignon grains,* contain *chryso-rhamnin.* [RHAMNUS INFECTORIUS, NAT. HIST. DIV.]

Purree, or *Indian yellow.* [PURREIC ACID.]

Quercitron, the bark of a tree. [QUERCITRIN; also QUERCUS TINCTORIA, in NAT. HIST. DIV.]

Rhubarb yellow. [CHRYSOPHANIC ACID.]

Saffron, the internal part of a flower. [SAFFRANIN; also CROCUS SATIVUS, in NAT. HIST. DIV.]

Turmeric. The root of a tree. [TURMERIC; CURCUMIN; also CURCUMA LONGA, in NAT. HIST. DIV.]

Weld. A dried plant. [LUTEOLIN; also RESEDA LUTEOLA, in NAT. HIST. DIV.]

Chrome orange is, as the name implies, a colour between yellow and red. [LEAD, *Dichromate of.*]

RED COLOURING MATTERS.

Alkanet red, sometimes called *Schnap's violet.* A spirit colour prepared from the root of a tree. [ANCHUSIC ACID; also ANCHUSA TINCTORIA, in NAT. HIST. DIV.]

Brazil-wood lake occurs under the names of *Ball alke, Berlin red, Florentine lake, purple, pink* or *crimson lake,* and *washing red.* [BRAZIL-WOOD, *Colouring Matter of*; also CÆSALPINIA, in NAT. HIST. DIV.]

Cinnabar, or *Chinese red, vermilion,* and *Paris red.* [MERCURY, *Sulphide of.*]

Chrome cinnabar, a very basic chromate of lead. [LEAD, *Chromates of.*]

Cochineal, a dried insect. Prepared as a lake, it occurs under the name of *carmine.* Many terms, such as *Paris lake, Vienna lake, &c.,* are applied indiscriminately to the colouring matters of Brazil wood and cochineal. [CARMINE; also COCCIDÆ, and COCHINEAL, in NAT. HIST. DIV.]

Garancin, prepared from madder. [GARANCIN.]

Madder, the root of a tree. [MADDER, *Colouring Matters of*; also RUBIA TINCTORUM, in NAT. HIST. DIV.]

Red lead, minium, or *mennie.* [LEAD, *Oxides of.*].

Red oxide of iron is found native. Its shades vary from a light to a brown-red. The common names of it are *Armenian bole, Berlin red, colcothar, English red, red ochre, burnt ochre, red earth, terra di sienna, mineral purple, stone red, Indian red.* [IRON, *Oxides of*; OCHRE.]

Sandal wood, or Saunders' wood, furnishes what is called *violet saunders,* the wood of a tree. [SANTALIN; also PTEROCARPUS SANTALINUS, in NAT. HIST. DIV.]

Safflower, bastard saffron, dried flowers. [CARTHAMIN; also CARTHAMUS TINCTORIUS, in NAT. HIST. DIV.]

Lac-dye, very similar to cochineal. [SHELL-LAC.]

Logwood furnishes to acids a valuable red. [HÆMATOXYLIN; also HÆMATOXYLON CAMPEACHIANUM, in NAT. HIST. DIV.]

Red enamel colours, for glass-staining, &c., are *purple of cassius* [GOLD], and *red oxide of copper.* [COPPER, *Oxides of*].

Aloes also furnish a red colouring matter. [CHRYSAMMIC ACID.]

BLUE COLOURING MATTERS.

Cobalt blue, Thénard's, Hopfner's blue, cobaltic ultramarine, oxide of cobalt precipitated along with alumina or phosphate of lime. [COBALT.] *Smalt, Saxon blue, King's blue,* a cobalt glass powdered. [COBALT.]

Copper blue, mountain blue, English or *Hambro' blue.* [COPPER, *Carbonate of.*]

Indigo is the base of several blue colours. [INDIGO; INDIGOTIN; also INDIGOFERA, in NAT. HIST. DIV.]

Lichen blue, litmus, turnsole, orchil or *archil,* and *cudbear,* are colours furnished by many lichens or liverworts. [See the respective names; also LICHENS, *Colouring Matters of*; also LICHENS, in NAT. HIST. DIV.] [BLUE.]

Prussian blue, Erlangen, Louisa, Saxon, Paris, or *Berlin blue.* [IRON, *Cyanides of.*]

Ultramarine, lapis lazuli, azure blue, Vienna, Meissner, and *Nuremberg ultramarine.* [ULTRAMARINE.]

Glass and enamel are coloured blue with cobalt oxide.

GREEN COLOURING MATTERS.

Arsenical greens occur under between forty and fifty different names, including *Brunswick, Scheele's* and *Schweinfurth green.* [COPPER, *Acetate and Arsenite of.*]

Chlorophyll, or *leaf green,* from grass, leaves, &c. [CHLOROPHYLL.]

Sap-green, buckthorn, vegetable, or *bladder green.* [SAP-GREEN; also RHAMNUS, in NAT. HIST. DIV.]

Blue and yellow are frequently mixed together to form green colours. Green ultramarine [ULTRAMARINE] also bids fair to eclipse the arsenical greens.

Glass, porcelain, &c., are coloured green by oxide of chromium [CHROMIUM] and oxide of copper. [COPPER.]

BROWN COLOURING MATTERS.

Umber, sienna or *chesnut brown,* is found native. By heat it assumes a darker tint, and is then known as *burnt umber.* It is chiefly oxide of iron with silica and alumina. [OCHRE.]

Sepia, a dried fluid contained in the cuttle-fish. [SEPIA OFFICINALIS, in NAT. HIST. DIV.]

Catechu, an extract prepared from the wood of a tree. [CATECHU; also ACACIA, CATECHU, in NAT. HIST. DIV.]

BLACK COLOURING MATTERS.

Black lead, a crystalline form of carbon. [GRAPHITE.]

Charcoal, under various forms. [BONE-BLACK; LAMP-BLACK.]

Burnt sugar is used to colour brandy, confectionery, and in the kitchen. [CARAMEL.]

Indian ink. [INK.]

Black dyes are produced in many other ways, all having for their object the formation of tannate and gallate of iron.

WHITE PIGMENTS.

White lead, or *flake white.* [LEAD, *Carbonate of.*]

Zinc white. [ZINC, *Carbonate of.*]

Chalk. [CALCIUM, *Carbonate of.*]

Plaster of Paris, or *gypsum.* [CALCIUM, *Sulphate of.*]

Heavy white. [BARIUM, *Sulphate of.*]

French chalk, or *talc.* [STEATITE, in NAT. HIST. DIV.]

Pearl white. [BISMUTH, *Basic Nitrate of.*]

Starch alone is supposed to be used by confectioners as a diluent of the sugar, flavouring agent, and colouring matter.

Glass is rendered opaque white by oxides of tin and zinc, or by phosphate of lime.

In the arts and manufactures, all varieties of colours, tints, and shades are produced by mixing those already enumerated with each other.

Mauve is the name of a very delicate and beautiful purple or lilac colouring matter, recently discovered by Mr. Perkins. (Much of the *mauve* colour now seen is, however, obtained from *Archil* by a new process.) The colours produced by it are quite permanent. Its application to dyeing purposes has been patented. Mauve is so called on account of its colour being similar to that of the petals of the common mallow

(*Malva sylvestris*); mallow being rendered in French by the word *mauve.*

The colouring matters of flowers are owing, according to Fremy and Cloez, to two principles, *cyanine* and *xanthine.* The blue tints are produced by cyanine; the rose tints by cyanine in the presence of an acid. Xanthine furnishes the yellow shades, becoming brown in the presence of alkalies from formation of *xantheine.* [CYANINE, and XANTHINE.

The dark *colouring matter of the eye* is said to be due to a substance called *melanine.* [MELANINE.]

Colouring matter of blood. [HÆMATOSIN.]

For the methods of fixing colours on fabrics, see DYEING and CALICO-PRINTING.

COLOURS. The word colour is used in many different ways. Besides its original meaning, in relation to the tints of rays of light, it has gradually come to be applied to the substances by which those tints are imitated.

Painter's colours, for house-painting and similar purposes, are mostly prepared from mineral substances (white lead, red lead, umber, ochre, &c.) ground up with linseed oil and turpentine to the state of a thick liquid. It would, perhaps, scarcely be supposed that 'Painters' Colours' appear in the Board of Trade tables, as an article of export, to the value of 150,000*l.* to 200,000*l.* annually.

The oil colours for artists are more carefully prepared than those for house-painting. They used to be sold tied up in small bladders; but an ingenious and more convenient arrangement is now adopted. Mr. Winsor's envelopes for colours, patented in 1840, consist of small metal or glass tubes, open at both ends, and provided with elastic pistons or plugs of cork or some similar material. The piston has a worm or nut in its centre, which corresponds to a screw attached to a handle rather larger than the tube. The open ends of the tube are covered with small metallic plates having holes in their centres. When the colour is placed in the tube, the arrangement of the apparatus is such as to keep the air from acting on it; and when any is required to be used, the screw is turned round, the piston is pressed down, and a little colour exudes from the lower end. These envelopes, like those of bladders, have however been superseded by a very ingenious contrivance, which has been generally adopted by artists, Mr. Rand's Collapsible Colour-tubes. These tubes were made the subject of a patent in 1842; the objects of which were to introduce a mode of punching out by dies the thin pieces of tin of which the tubes are made; and to make a screw cap at the mouth of the tube, to prevent leakage. These little tubes, by a gentle squeeze, are made to yield the colour at one end just in sufficient quantity for use.

Water-colours for artists include both vegetable and animal as well as mineral substances, and like the oil colours, are prepared with very great care. [COLOURING MATTERS.] They are prepared dry in cakes; in a slightly moist state in small cups of porcelain, gutta-percha, or tin; and in the collapsible tubes at first only used for oil-colours. From the care required in their preparation, water-colours of good quality were only obtainable at a comparatively high price, but the London Society of Arts has been instrumental in inducing manufacturers to produce shilling boxes of water-colours applicable to the wants of students in schools of design, and other persons in humble life, of a character equal to those previously obtainable at a much higher rate.

Mr. Smith of Blackford communicated to the Royal Scottish Society of Arts, a paper showing that when chromate of lead is mixed with muriate of ammonia, and subjected to the action of heat, a substance is obtained of a different colour from either of the matters used. If the proportions of the substances be varied, and different degrees of heat applied, distinct colours and tints will be the result. Thus, when 5 parts of chromate of lead, and 1 part of muriate of ammonia are heated to redness in a crucible, a red colour is obtained; a blue colour is formed by heating 10 parts of muriate of ammonia, and 1 part of chromate of lead to ebullition; and a green is produced when the last mixture is heated nearly to redness. By employing various proportions of the substances, and different degrees of heat, a great variety of tints are formed—scarlet, orange, brown, blue, purple, green, yellow, and others. It is conceived by the discoverer that these properties may lead to useful applications in the arts.

The progress of chemistry naturally enlarges the list of substances from which colours can be obtained; and we find numerous patents bearing on this subject. A few years ago it was hoped that pigments for house-painters might be obtained from the residuum found in galvanic batteries, after the decomposition of those metallic compounds concerned in producing the galvanic action; the pigments are certainly produced, and batteries have been used expressly to this end; but the electro-colours, as they are called, have scarcely become a marketable commodity.

COLOURS ACCIDENTAL. [ACCIDENTAL COLOURS; LIGHT.]

COLOURS COMPLEMENTARY. [ACCIDENTAL COLOURS; LIGHT.]

COLOURS OF PLATES. [LIGHT.]

COLTSFOOT, the name given, owing to the shape of the leaves, to the compound indigenous plant, called by botanists *Tussilago Farfara.* Its Latin name has reference to its reputed virtues as a means of driving away coughs. If it be, as conjectured by Dr. Sibthorp and others, the Βήχιον of the Greeks, its fame descends from a very remote period; but its sensible properties do not seem to justify its character. The flowers and leaves are used in almost every way and means possible, both fresh and dry. The flowers are slightly odorous, and very slightly bitter, the leaves are more bitter; the latter somewhat mucilaginous. These when young, boiled, form a good spring vegetable, which might be more frequently used, especially by the poor.

No analysis (quantitative) of coltsfoot has been made, but the chief constituents are: mucilage, bitter extractive, tannic acid, colouring matter, salts, and woody fibre.

The properties are feebly tonic, demulcent, and emollient; on the latter account the leaves are sometimes used as an external application for poultices or fomentations. The vaunted properties of coltsfoot find no credence with the educated, and it only retains its reputation as a popular remedy. Hence it is chiefly sold as a *nostrum,* in the form of lozenges, which, when harmless, have their virtues increased by adding extract of liquorice and other demulcents, but which are often rendered hurtful and even destructive by morphia and other powerful narcotics. Essence of coltsfoot is a stimulating compound of balsam of tolu, compound tincture of benzoin, with a double quantity of rectified spirit of wine. Most improper at the beginning of colds, the root deserves attention as an astringent of considerable power.

COLUMBA NO'ACHI (constellation), the dove of Noah, a constellation formed by Halley, close to the hinder feet of Canis Major. The following are the principal stars in this constellation:—

Character.	No. in Catalogue of British Association.	Magnitude.

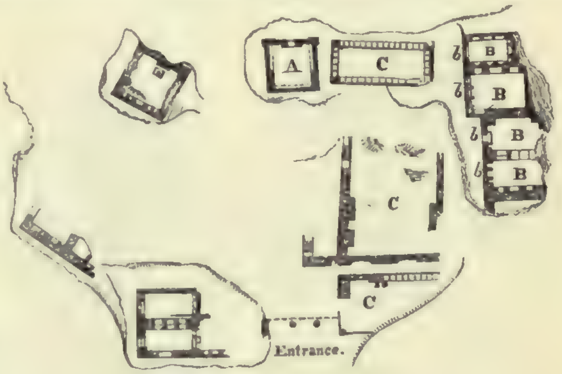
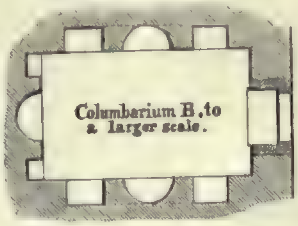
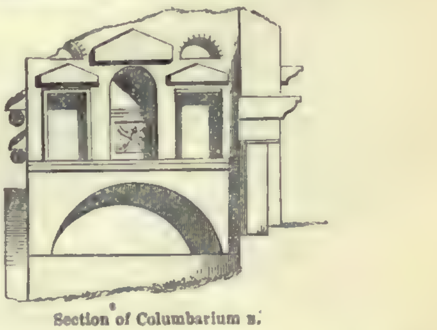
α	1802	2
β	1878	3
γ	1922	4

COLUMBA'RIUM, a place of sepulture used for the ashes of the Romans after the custom of burning the dead had been introduced among them. It is usually a square or oblong room, the walls of which are pierced with small cells or niches for holding the urns which contained the ashes of bodies which had been subjected to burning. The word columbarium signifies a dovecote; and its application to the

Plan of Columbarium, discovered in the gardens of the Villa Doria Pamfili at Rome.







Section of Columbarium B.

Roman places of interment has arisen from the resemblance between the small arched holes which contain the sepulchral urns and the recesses formed for the doves in a dovecote.

This application of the word columbarium is proved by ancient inscriptions, but we are not aware that the term is used in this sense by any extant Latin writer.

In the Villa Doria Pamfili at Rome was discovered, in 1822, a very extensive columbarium, or rather an assemblage of columbaria, which are shown on the accompanying plan. It was surrounded by a wall, with a triple entrance, formed by two columns. The columbaria, which are on a very diminutive scale, are placed without any regularity. One building, A, superior in workmanship to the others, appears to have been a small temple in antis, built with red bricks, set with very delicate joints, and rubbed on the surfaces. The chambers, B, B, B, &c., were superior columbaria, with large niches, which contained double ollæ or vases for the ashes of the dead, with small tablets let into the wall below each niche. The small structures at C, C, which most resemble the dovecotes, are supposed to have been the sepulchres of the slaves. They are built with reticulated work, and are filled with several rows of pigeon holes, which contain ollæ: they have no inscriptions. The brickwork of these columbaria is of several dates, if we may judge from the diversity of construction. The chambers B *b*, B *b*, have stone doorways, Egyptian in character. The interior of these little structures, and the temple, have been stuccoed and ornamented with reliefs, and painted. In the columbaria of wealthy families a considerable amount of decoration was sometimes expended. In the immediate neighbourhood of the Columbarium, in the Villa Doria Pamfili, are numerous inscriptions, tablets, and monumental urns, which belonged to these sepulchres, but having been removed from the ollæ, they lose part of their interest. There are several columbaria in the neighbourhood of Rome, among which that of the family Pompeia is remarkable for its tablets and urns. There is another and very fine sepulchral chamber, discovered in the year 1746, near the gate of San Sebastian at Rome.

COLUMBIN ($C_{22}H_{12}O_7$?), the supposed active principle of the Columba root. The root contains, according to Buchner—

Bitter substance with resin	12·2
Resinous colouring matter	5·0
Wax	·2
Gum	4·7
Starch	25·0
Pectin	17·4
Fibre	22·6
Water, salts, and loss	12·9
	100·0

Columbin is obtained from the alcoholic extract of the root, and crystallises therefrom during spontaneous evaporation. It is purified by filtering its alcoholic solution through animal charcoal, and it then possesses the following properties: It crystallises in bitter, inodorous, colourless rhombic prisms, possessing neither acid nor alkaline reaction. Boiling alcohol of ·835 dissolves from $\frac{1}{30}$ to $\frac{1}{40}$ of its weight. It is also soluble in caustic alkalies. Taken internally it is poisonous.

COLUMBIUM (Ta) *Tantalum*. A metal found in 1802, in two Swedish minerals, *tantalite* and *yttro-tantalite*. The first, somtimes called also *Columbite*, occurs amorphous and nodular, and also crystallised in the form of a right rhombic prism. The massive variety is either granular or compact: the crystals are grayish-black: fracture uneven; hardness, 6: sp. gr., 6·038; lustre, imperfect metallic; it is opaque. It contains about 80 per cent. of oxide of columbium, 12 of oxide of iron, and 8 of oxide of manganese. The yttro-tantalite contains oxide of columbium, *yttria*, and some other substances.

Columbium is obtained with great difficulty. Berzelius procured it by heating potassium with the potasso-fluoride of columbium. It is a black powder, which by the burnisher acquires the colour and lustre of iron. The specific gravity is about 6. It is nearly insoluble in acids. When heated in the air it is oxidised, and converted into columbic acid.

Oxygen and *Columbium* combine in two proportions, forming columbic acid and oxide of columbium.

Columbic acid may be obtained by burning the metal in the air; it is colourless, insipid, and does not act upon vegetable blue colours. When heated with charcoal it is reduced to the state of oxide. If heated with iron it loses oxygen, and an alloy of iron and columbium is formed. Columbic acid combined with water forms a very white hydrate, which reddens vegetable blues. It combines with salifiable bases to form salts which are called *columbates*, but no one of them is of any importance, or applied to any purpose whatever.

Columbic acid is composed of—

3 equivalents of oxygen . . .	24
1 equivalent of columbium . .	185
Equivalent . .	209

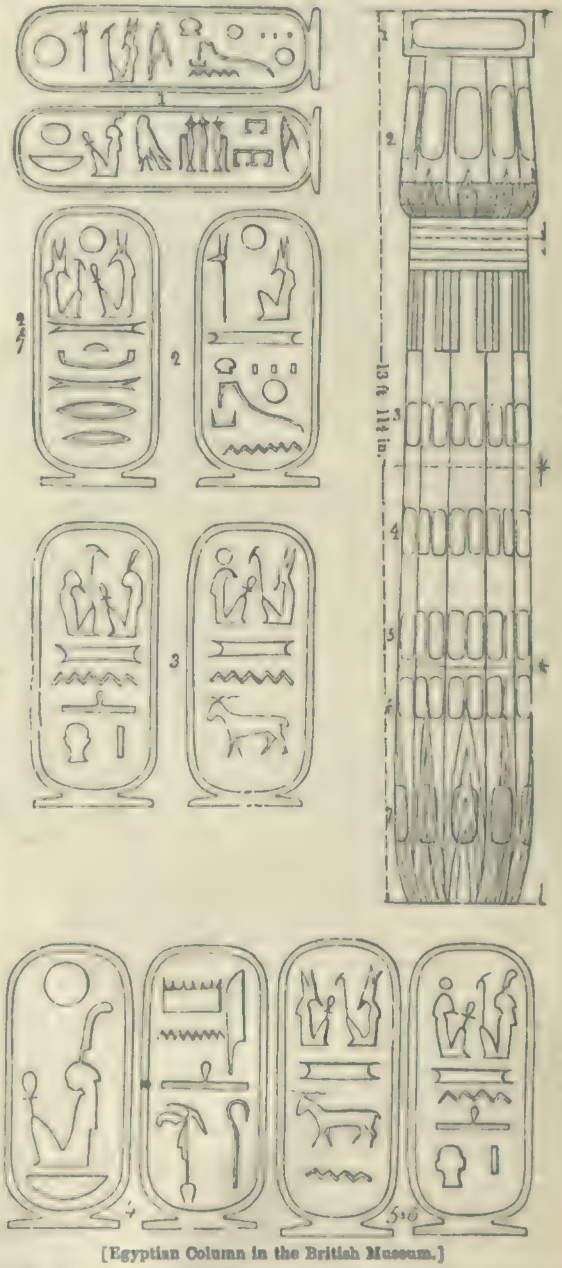
Oxide of Columbium is obtained by heating columbic acid to whiteness in a covered crucible. It is of a grayish black colour, very hard, and almost infusible.

Oxide of columbium consists of—

2 equivalents of oxygen . . .	16
1 equivalent of columbium . .	185
Equivalent . .	201

Columbium combines also with chlorine and sulphur, &c., but these compounds are little known and of no importance.

COLUMN, from the Latin *columna*. The column is a shaft of wood, stone, or iron, in the form of a truncated cone, a little swelled from the straight line at about one-third its height from the lower extremity: this swelling is called the entasis. The column is furnished with a base at the foot and a capital at the head of the shaft. Columns are of various proportions and kinds: circular on the plan, and rarely polygonal. The Romans had five models of columns, which were called orders; but the Greeks, from whom the Romans appear to have derived their architecture, only three. The Egyptians used columns, but they were very different in their form and proportions from both the Roman and Greek examples. Very different again from all these were the columns in Assyrian architecture. [NINEVEH, ARCHITECTURE OF.]



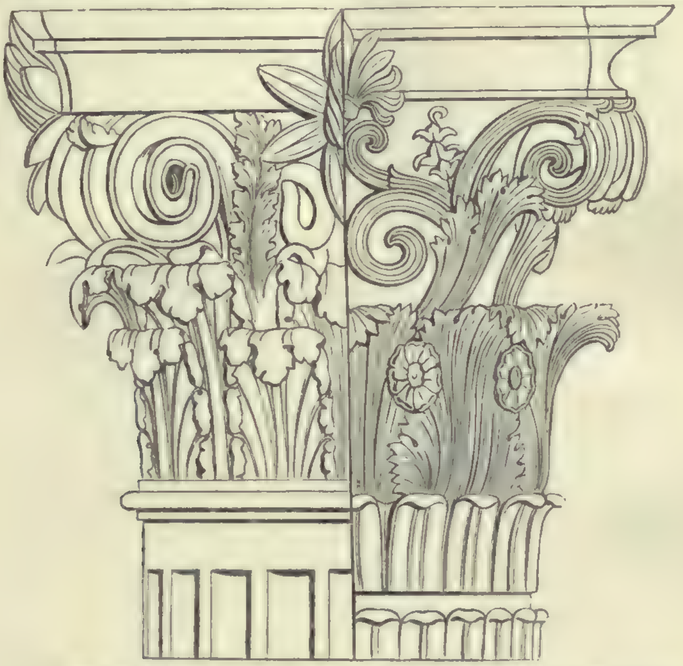
[Egyptian Column in the British Museum.]

The elliptical figures are the cartouches on the column, drawn to a larger scale. The height of the column is 13 ft. 11⅝ in.

The five Roman orders are the Corinthian, Ionic, and Composite, which is a mixture of the two former, and the Doric and the Tuscan,—

two orders very similar in appearance and character to each other. [ROMAN ARCHITECTURE.]

The Greek Corinthian, Doric, and Ionic differ from the Roman. The proportions of the orders vary slightly in almost every example of antiquity; but the distinguishing features are the capitals. The bases also vary in proportion, and sometimes in the profiles of their mouldings; but this is not so apparent to an ordinary observer as the difference in the capitals of the orders.



[Half the Corinthian capital of the Temple of Vesta, at Tivoli.] [Half the Corinthian capital from the monument of Lysicrates, at Athens.]

The Corinthian capital consists of the leaves of the acanthus [ACANTHUS] with two spiral horns at each of the four angles of the abacus. In the centre between these horns are two smaller spirals attached to the bell of the capital; under these are two rows of acanthus leaves regularly disposed, eight being placed in each row, and eight large double leaves supporting the angular horns, called also volutes. These are the leading features of the Corinthian capital, although some are more ornamental than others, and have enriched details about the abacus and the bell, which others have not. The most striking difference between the character of the Greek and Roman foliage of the Corinthian column is this: the leaves of the Greek have angular points, and are almost straight on the sides; the Roman are rounded on the sides; the section of the hollow of the Greek is angular, while the Roman is either a segment of a circle, or formed of two segments of a circle meeting in the centre of the hollow of the points of the acanthus leaf. The Greek leaves may be said to have more of the natural character of the acanthus, or the thistle, while the Roman is more artificial, and consequently less like the model from which the Greeks drew their capital. There are examples of the Greek Corinthian capitals, although much mutilated, in the Elgin collection in the British Museum; and casts of the Roman examples from the temple of Jupiter Stator, Mars Ultor, and the Pantheon, also in the British Museum. The bell of the Corinthian capital may be clearly understood from the annexed drawing of the mutilated single Corinthian capital found in the Temple of Apollo at Bassæ, near Phigaleia; and the accompanying drawings of Egyptian capitals, from the French work on Egypt, will show better than any elaborate description the strong resemblance of the Egyptian capital to the bell of the Corinthian capital, as we meet with the latter in the Temple of Jackly near Mylasa, and the Choragic monument of Lysicrates at Athens. The

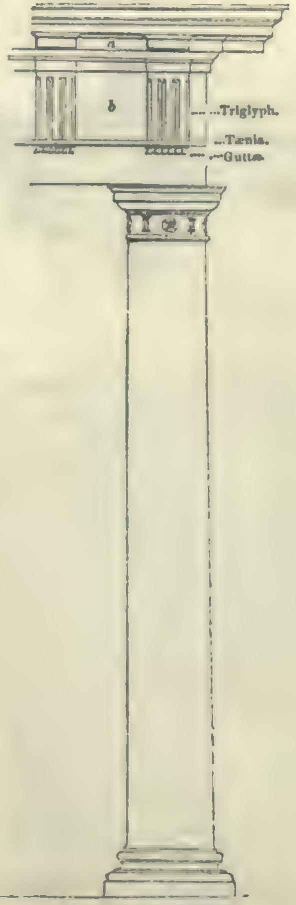
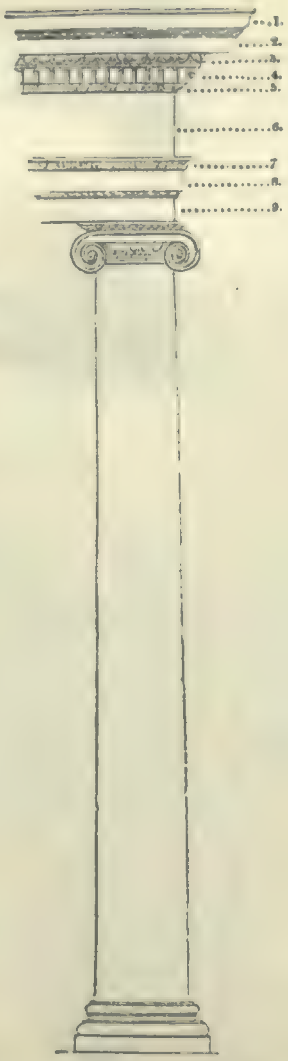
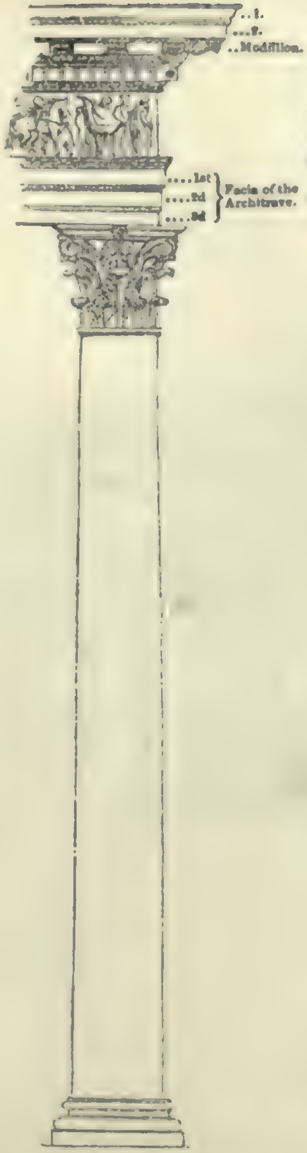
TUSCAN.



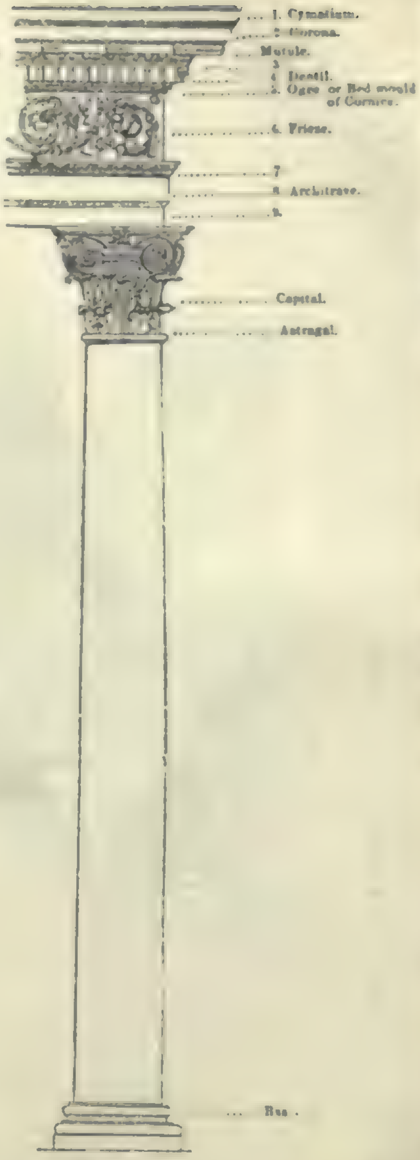
ROMAN DORIC.



ROMAN IONIC.



CORINTHIAN.

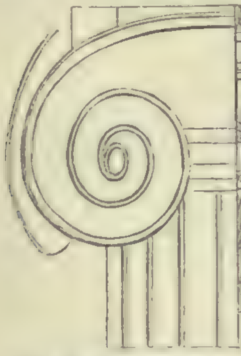


COMPOSITE.

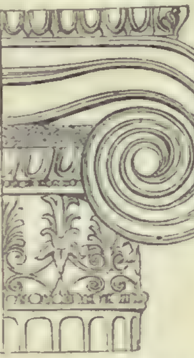
[Drawn to the same scale of two Modules, by dividing the diameter into two parts, and each part into thirty parts or minutes.]

order of the Temple of Vesta at Rome, which very much resembles the order of the Temple at Jackly, was most probably copied from it. Among other peculiarities, it has the same defect of the leaves projecting beyond the line of the shaft, and is the only building of the Corinthian order in Rome which has a Greek character. Some Greek Corinthian capitals have only one row of acanthus leaves, and are without the horns under the abacus, the bell being decorated with flat leaves called water-leaves, as in the Tower of the Winds at Athens.

The Ionic column is characterised by the two large spirals or volutes on two of its faces, connected under the abacus. The other sides connect these faces at right angles by a kind of baluster placed horizontally. Beneath this baluster and the astragal surmounting the top of the shaft of the column is the neck of the capital, which in some Greek examples is richly decorated; the baluster is also occasionally enriched. In some Ionic capitals all the faces of the volutes are conjoined at the extremities, the faces being curved inwards as in the Temple of Apollo at Bassæ. Ionic columns placed at the angles of porticos have sometimes the volute ingeniously formed at the angle, so as to present a voluted face either ranging with the volutes of the portico, or with the volutes of the column at the side of the portico. The angle column of St. Pancras Church, London, has the angular faces curved. The angular volutes in some Roman examples are formed of two half volutes placed at right angles to each other. The bases of the Ionic vary perhaps more than any other order. In Roman examples the Attic base is employed.



[Half the Ionic capital of the order employed in the cella of the Temple of Apollo at Bassæ.]



[Half of the capital of the Erectheum.]

The Composite column, as its name implies, is a compound. It is formed of the Corinthian and Ionic, but partakes more of the Corinthian character and proportions.

The Roman Doric and Tuscan columns are shafts with moulded capitals and bases, the Doric only having a slight decoration of rosettes and buds in the neck of the capital, and some trifling additional mouldings. The Grecian Doric differs from the Roman both in proportion and in the mouldings of the capital, in the flutings being without fillets, and in its being almost always without a base.

An order includes the column with the whole of the entablature, or the superstructure raised on it, which is divided into architrave, frieze, and cornice.

All the great architects of the cinque cento, and after them those of the later Italian and French schools, have differed in the proportions and details of the orders, but for the most part in a trifling degree. The proportions of the five Roman orders which we have adopted here as our rule are those laid down in Sir William Chambers's 'Architecture,' and which are generally employed by the English architects of the present day. The proportions of the orders used by the Greeks are from the authority of Stuart. The measure by which the proportions of the orders are determined, is the diameter of the base of the shaft of the column, which is divided into two parts called modules, and each module is divided into 30 parts called minutes. This scale is in general use in all countries which derive their architecture from the Greeks and Romans.

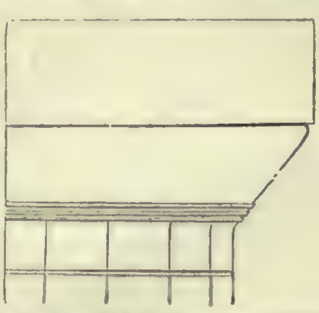
Thus the height of the shaft of the Tuscan order, from the upper line of the fillet of the base to the upper line of the astragal of the neck of the column, is 12 modules or semidiameters high; the base, including the plinth, is 30 minutes; the capital, 30 minutes; the architrave, 31½ minutes; the frieze, 31½ minutes; the cornice, including the bed-mould or ogee, 42 minutes; and the projection of the cornice, 42 minutes. The shaft of the Doric order is 13 modules 28 minutes; the base, 30 minutes; the capital, 32 minutes; the architrave, 30 minutes; the frieze, 45 minutes; and the cornice, 45 minutes. The projection of the cornice is 57 minutes. The shaft of the Ionic order contains 16 modules 9 minutes; the base, 30 minutes; the capital, from the upper line of the astragal, 21 minutes; the architrave, 40½ minutes; the frieze, 40½ minutes; and the cornice, 54 minutes. The projection of the cornice is 54 minutes. The Corinthian order has the shaft 16 modules 20 minutes; the base, 30 minutes; the capital, 70 minutes; the architrave, 45 minutes; the frieze, 45 minutes; the cornice, 60 minutes; and the projection, 58 minutes. The Composite order is similar in its general proportions to the Corinthian; and the columns of the Roman orders diminish in diameter about one-sixth; that is, are 50 minutes at the upper diameter of the shaft. But by a reference to the proportions of some of the columns of ancient edifices at the end of this article, some variations from this proportion will appear.

The Greek Doric varies very much in its proportions. The Doric of the Parthenon has the shaft and capital 10 modules 8 minutes high, and the entablature 3 modules 15 minutes. For a scale of the proportions of the leading features of some of the best known examples of antiquity, see the end of this article.

The Tuscan order, which is simple in its design, has a base formed of a plinth or squared piece of stone as a foundation, and a torus above it, surmounted with a fillet. The shaft is terminated with a fillet and an astragal, on which the capital is set, consisting of a necking (a prolongation of the shaft) and an ovolo moulding supporting the squared abacus, which is surmounted with a fillet. The architrave is a plain face with a broad fillet. The frieze also is a plain face. The cornice consists of an ogee, a fillet, an ovolo forming the bed-mould of the cornice, which consists also of the corona and fillet, surmounted with a cymatium.

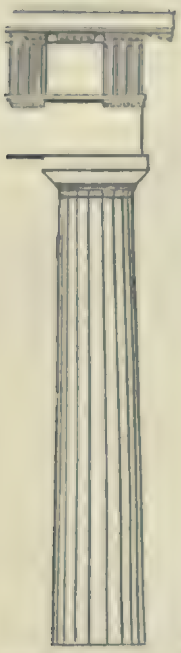
The Roman Doric, resembling in some particulars the Tuscan, is however very much richer. The Doric base consists of a plinth, a torus, a hollow moulding with a fillet above and below it; on the upper fillet is another torus and fillet, from which rises the shaft, curved where it springs from the fillet: the lower diameter of the shaft of a column is always measured from the point where this curve ends, and is joined to the straight line of the shaft. This is the Attic base, which is most commonly used in all the orders except the Tuscan. The shaft of the Doric is terminated like the Tuscan, and from the summit springs the capital with a neck enriched with rosettes and buds. Above the necking are three flat annular rings or fillets, then an ovolo moulding surmounted with the abacus, which is finished with a small ogee moulding and fillet. The architrave is a plain face, with a flat band (*tænia*) and a fillet under the triglyph, with six guttæ or drops under the fillet. The frieze is divided into compartments with a triglyph over each column and one or more between, according to the width of the intercolumniation. The triglyphs which project slightly from the face of the frieze are channelled with angular channels and two half channels at the sides of the triglyph. The metope, or space between two triglyphs, is square or nearly so; this, however, depends on the intercolumns. The triglyphs are bound together by a facia, surmounted by a small fillet under the bed-mould of the cornice, which is an ovolo moulding or an ogee. Over this is the mutule band with the mutules, square in form, projecting over the triglyphs; an ogee surmounts the mutules and the mutule band. The mutules support the cornice, consisting of the corona, an ogee and fillet, and a cavetto or hollow moulding. The soffit or under-side of the cornice is sometimes enriched with pannels, and guttæ are placed under the mutules. The Doric of the theatre of Marcellus at Rome has dentils with an ogee bed-mould in the cornice in lieu of the mutules; and the basilica by Palladio at Vicenza is without either mutules or dentils, having instead of them a bold ogee and ovolo moulding, and the architrave divided into two faciæ.

The Greek Doric differs considerably from the Roman, being almost always executed without a base. The flutings of the shaft are twenty in number without fillets; some examples are fluted only at the upper and lower extremities. The capital consists of a solid-looking abacus without any moulding above it, but supported by a very elegantly-curved echinus-moulding, which swells gradually out of the line of the shaft, being bound round by three annulets or rings near the top of the shaft, and on the under extremity of the echinus. A part of the shaft is also cut off by a sinking, or channel, cut into the shaft, forming the necking of the capital. The features of the entablature are very simple. [GREEK ARCHITECTURE.] The triglyphs are not very dissimilar in the Roman and Greek Doric, except in the setting them off on the frieze. In the Roman they are invariably set over the centre line of each column, the angle of a building being terminated by a portion of a metope. In the Greek the triglyph is invariably com-

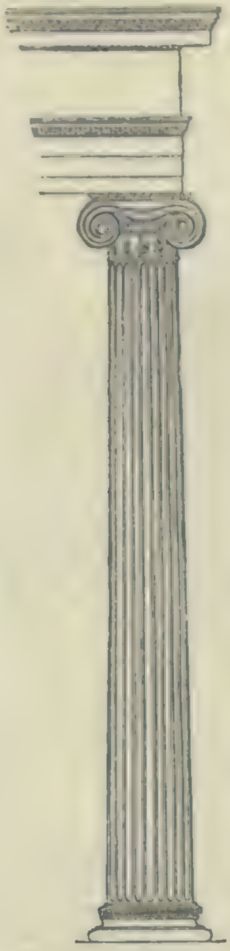


[Half the capital of the Parthenon at Athens.]

menced at the angle of the building, and not over the centre line of the column generally.



[Greek Doric order of the Parthenon.]

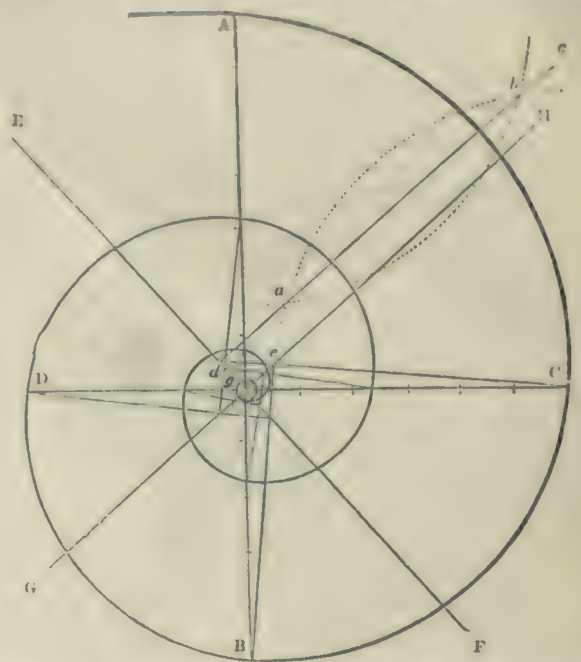


[Ionic order of the Erectheum at Athens.]

The Roman Ionic has an Attic base. The capital is formed with two volutes on two faces, and the volutes are connected by horizontal lines, though sometimes, like the Greek, the curved line is employed. The abacus is formed of a fillet and an ogee. Under the horizontal lines connecting the volutes is an echinus and astragal or bead-moulding enriched. The architrave is divided into two faciæ: the upper face is surmounted with a fillet and ogee enriched, and the lower with a small echinus, also enriched, having a narrow fillet underneath it. The friese is usually plain, though the temple of Fortuna Virilis at Rome has a meagre decoration. The cornice is supported by an ogee moulding and dentils surmounted with a fillet, a bead moulding, and a large enriched echinus moulding. The cornice itself consists of a corona with a small ogee and fillet, on which is placed a cymatium. The volutes of the capital are connected at the sides by a pulvinus, or cushion, commonly called the baluster of the Ionic order. The Greek Ionic varies in proportion, and is superior in beauty to the Roman example. The method of drawing the Roman volute called Goldman's volute, is described in Sir William Chambers's Architecture.

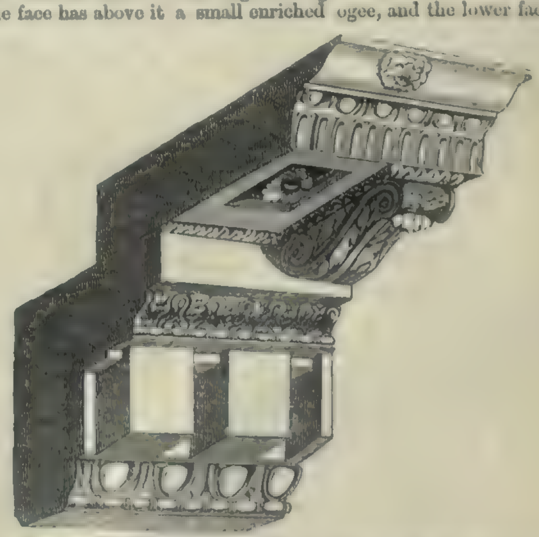
The following is a very accurate method of drawing the Greek volute similar to the form of the volute of the Erectheum or Minerva Polias at Athens. Divide any perpendicular height, A B, into 12 equal parts. Through the 7th division g from the top, draw the line C D at right angles to A B. Then upon the line C D, from the centre g, set off towards C six of the seven divisions between A and g. Draw the lines G H and E F, at angles of 45 degrees to the lines A B and C D respectively. Bisect the line joining A and C by $b\ a$, and produce it till it cuts E F in d. Then from d, as a centre, with the radius d A or d C, describe the quadrant A C of the volute. Then join C d, cutting the line G H in e; from the point e describe with the radius e C or e B the quadrant C B, passing through B, the extremity of the line A B; and proceed in this manner with all the quadrants till you touch the centre. The centres of the segments A C, C B, B D, &c., are always found on the diagonal lines E F and G H.

The best examples of the Roman Ionic order are fluted, with twenty-four flutings, or semicircular channels, divided by a narrow fillet, which is part of the surface of the shaft of the column. Some Greek examples, as at Bassæ, have only 20 flutings, and are without fillets.



[Method of drawing the spiral forming the volute of the Greek Ionic of the Erectheum and Minerva Polias Temples, at Athens.]

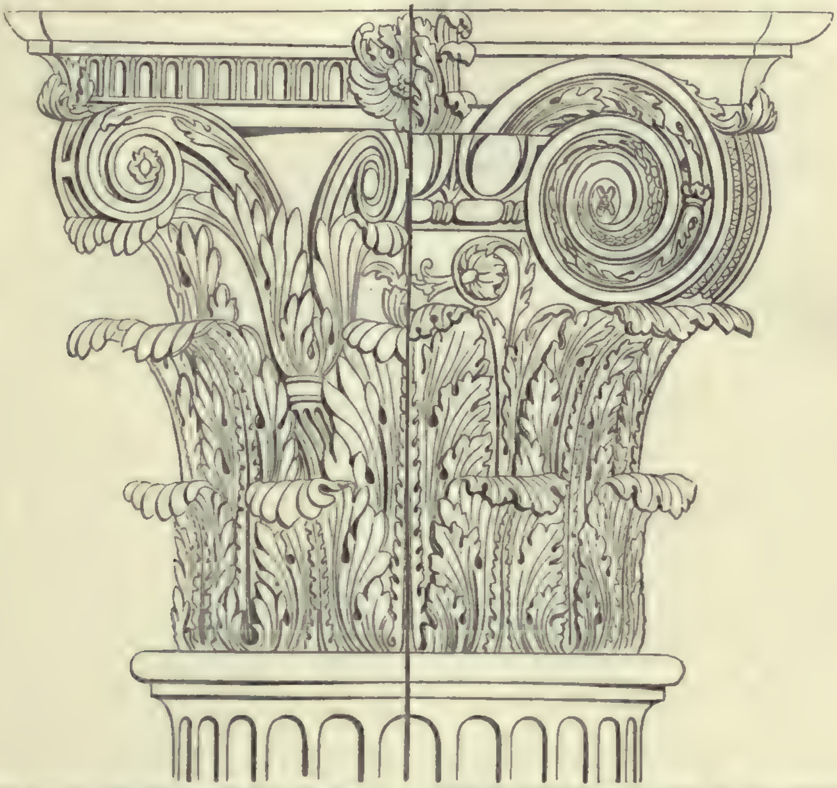
The general proportions of the Corinthian and Composite are the same, and they differ but slightly in their mouldings and enrichments. The base of both Corinthian and Composite is the Attic. The flutings of the shaft are, as in the Ionic, twenty-four, and divided by fillets. The capital is composed of two rows of acanthus leaves, eight in each row, and the upper row is placed between and over the divisions of the lower row. Four spiral volutes in each face rise out of two bunches of the acanthus leaf, and two of them are connected at the angles, and support the abacus formed of a cavetto and fillet, and an echinus, which are, except the fillet, sometimes enriched. The face of the abacus is formed of the segment of a circle, whose extremities are supported by the spiral horns or volutes. The connected ends of the abacus form a narrow face, round which the mouldings are continued, although in some rare instances these ends are pointed by the intersection of the two curved faces of the abacus. The leaves and volutes are carved round what is a continuation of the shaft, formed into the shape of a bell reversed. The lower row of leaves generally follows the line of the shaft, which is considered the best system of setting them off round the bell, although the Temple of Vesta at Rome has the leaves projecting beyond the shaft, and Inigo Jones has adopted this system in the Banqueting-house at Whitehall. The Corinthian architrave is divided into three faces, the Composite into two. The upper face is surmounted with an astragal and ogee enriched with a fillet; the middle face has above it a small enriched ogee, and the lower face an enriched bead. The frieze is enriched with figures or ornaments. The cornice is distinguished by its modillions and dentils; the latter are supported by an ogee and astragal enriched; the former by an enriched



[A Modillion or Console of the cornice of the Temple of Jupiter Stator at Rome.]

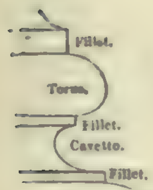
echinus and astragal. The modillion, which is set at intervals under the corona, will be better understood by the annexed view of a modillion of the Temple of Jupiter Stator, showing also the soffit, or under-side of the corona, with the enriched pannel between the modillions. The modillions support the corona, which is terminated with a cymatium, and this moulding, in the example before us, is decorated with lions' heads.

In the Composite order, mutules are sometimes employed instead of

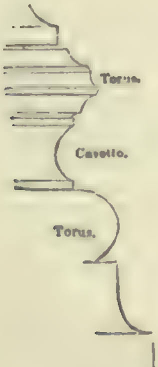


[Half the Corinthian capital, from Sir Wm. Chambers.] [Half the Composite capital, from Sir Wm. Chambers.]

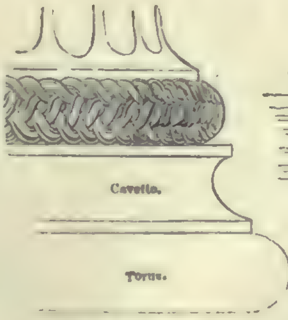
the Corinthian modillion. The orders are sometimes set on pedestals, consisting of a square shaft, called the die, with a moulded base set on a deep plinth. The die is surmounted with mouldings forming a capital, but in reality resembling more the cornice of an entablature.



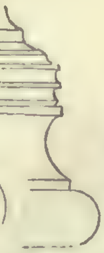
[Attic Base.]



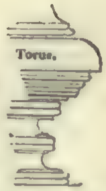
[Ionic Base at the Propylæa of Eleusis.]



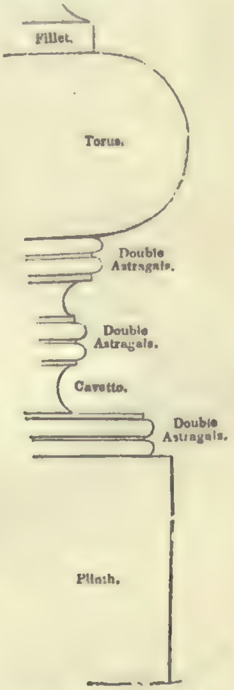
[Base of the Erectheum.]



[Base of the Minerva Polias.]



[Base of the order of the Temple of Apollo Didymæus.]



[Profile of the bases of the columns employed in the Temple of Minerva Polias, at Priene.]

Chambers allows, for the proportion of the die of the Tuscan pedestal, two modules, twenty-four minutes; for the Doric, three modules, six minutes; the Ionic, three modules, eighteen minutes; and the Corinthian and Composite, four modules. The bases and capitals are respectively—Tuscan, base twenty-eight minutes, capital fourteen minutes; Doric, base thirty two, and capital sixteen minutes; Ionic base thirty-six, and capital eighteen minutes; and Corinthian, base forty, and capital twenty minutes.

Greek mouldings vary from the Roman, and are remarkable for being almost invariably drawn by the hand, and not formed, as in the Roman examples, of parts of circles struck with the compasses.

The flutings of columns vary in the depth and form of their curves; some, as in the Doric orders, are flat segments, without fillets between them, others are deep segments and semicircles, and others are semi-elliptical, and sometimes more than semi-elliptical, on the plan, as in the Jupiter Stator. Some columns of antiquity are decorated with spiral flutes, and some with leaves, as in the Temple of Clitumnus, and in a fragment in the British Museum.

The method of drawing the entasis of the columns employed in Roman architecture is described by Chambers, p. ii. of the Preface. It is done by means of a sliding rule, called the rule of Nicomedes.

Some account of the entasis of columns, by Mr. Jenkins, is given in the 4th vol. of Stuart's 'Athens,' with comparisons of the entasis of several columns, and more fully and elaborately in Mr. Penrose's treatise on the Parthenon, published by the Dilettanti Society. The Greek entasis is much more subtle than the Roman.

We may here observe, generally, that the principle of a base is support, which is admirably shown in the Attic base, where the two tori are proportioned and arranged, with the graceful sweep of the cavetto or hollow moulding between them, to sustain the shaft. The hollow-moulding gives additional height to the base, and the profile is in no part within the perpendicular line of the shaft, which would give it a weak appearance. The annexed variety of bases, from Greek examples (see preceding page), present some of the beauties and some of the defects even of Greek architecture. The base of the Apollo Didymæus shows weakness, and the torus of the Minerva Polias, at Priene, appears too heavy for the delicate astragals and cavettos beneath.

Some columns, instead of being fluted the whole height of the shaft are, for about one third from the base, made polygonal, each side being the width of the flute. This is particularly the case at Pompeii, where the Doric columns are often very slender. In the internal order of the Pantheon, the flutings are filled with cabling about one-third of their height. Cabling is a carved band projecting out of the fluting.

Vitruvius makes the height of the Doric (Roman) seven times the diameter; the Ionic, 8½; and the Corinthian, two-thirds higher than the Ionic, or nine diameters and one-sixth. The proportions of Palladio and Vignola differ; the latter are, we believe, preferred by the French school. See the Architecture of Palladio and Vignola. The proportions of the columns given above are from Stuart's 'Athens;' Taylor and Cressy's 'Rome;' 'Ionian Antiquities;' 'Unedited Antiquities of Attica,' &c.

In studying these works the student should be guided by the figures denoting the dimensions rather than by the outlines.

COLUMN. This term is applied to any formation of troops in which the divisions are placed behind one another exposing a narrow front to the enemy. Thus a column of battalions is formed by a number of successive battalions being deployed close behind one another; while a battalion is said to be in column when the companies of which it is composed are deployed in rear either of one of the flank companies, or in rear of the two centre companies or two centre subdivisions. A battalion is said to be in open column when the distance between the companies is such as to admit of their wheeling into line; and to be in close column when the front rank of one company is within a few paces of the rear rank of the one before it, while the half distance column is intermediate between the two.

The formation of the Greek and Roman armies was almost wholly in column, both for attack and defence. And it was only on the introduction of fire-arms and field artillery that, from the ravages committed in dense masses, a more extended formation was adopted. Gustavus Adolphus was one of the first to employ a more open formation.

In the wars of the French Revolution, at the close of the 18th century, the dense column was universally employed, almost of necessity, as the raw levies were not sufficiently trained to be easily handled in any other formation, and the loss of life entailed was not considered by their generals, to whom success, however dearly purchased, was the only obligation. From these victories and those of the first Napoleon, who also employed very dense columns in attack, it resulted that close columns came much into repute, and their advantages as compared with other formations are much contested points among military writers, especially between English and foreign authors; the former principally upholding the formation in line, which had been so successfully applied by the Duke of Wellington in the Peninsula and at Waterloo against the columns of the French. Still we must not blind ourselves to the fact, that a formation which can be applied with troops of such *morale* as the English may not be the best with others. Jomini, when discussing this question in his 'Précis de l'art de la Guerre' remarks, "Dès lors quelle serait l'armée Européene (si l'on excepte les Anglais), que l'on pût se hasarder à deployer en lignes sur deux rangs." And as a three rank formation makes a column too dense, and it would be next to impossible to change from a three to a two rank formation, according as a deployment or column was required, he recommends the constant employment of small columns of attack on a two rank formation.

From the great advantage that the formation in column gives in the movement and handling of troops, and the impossibility of conducting extended movements in line, even if there were any object in attempting it, the column will always in some shape or other be employed in all the preliminary dispositions of a battle, and it is only when within range that the question arises as to formation. For the offensive, the objects to be kept in view in the formation of troops, are mobility combined with solidity and impulse; while for the defensive, solidity should be united with the greatest possible amount of fire. Now the column, if not too deep, combines the former qualities in the highest possible degree, and in an attack firing is not required; indeed, if the men once commence to fire, the attack will in all probability fail, for the impulse and impetuosity of the charge being lost, if received by a steady fire from the enemy, they soon get into confusion and retire. At the same time it must be remembered, that the deeper the formation the greater will be the carnage, especially if artillery be employed in the defence of the position attacked; and therefore, if the troops are sufficiently steady and well disciplined to be managed under fire in line they will have a great advantage. The deployment from the column into line for attack, should not however take place at too great a distance from the point attacked, as, especially in moving over rough ground, troops in line soon lose their formation; whilst on the other hand, if the deployment is too long deferred, and the column while deploying is received with a heavy fire, it is likely to be thrown into disorder, and if then promptly charged, (as at Waterloo), will probably be routed.

Jomini, while condemning the formation of troops in large masses, as at Waterloo, argues in favour of battalion columns, formed on the two centre companies, with two companies as skirmishers, thus making the depth only six ranks, as a good general formation for attack. For he says, that although at Talavera, Busaco, Fuente d'Onor, Albuera, and Waterloo, heavy columns, (in one case twelve battalions deployed behind one another, or a depth of thirty-six ranks,) had been annihilated by the fire and attack of the English infantry in line, on front and flank, yet that this is no proof against small battalion columns, which have not been sufficiently tested. And for defence, he considers the first line should be deployed, and the second in battalion columns. The success of the line or column will, however, depend upon its proper application by the general, according to the modifying circumstances of ground, whether broken or even, of discipline and of *morale*. And no general rule can be laid down, though the Duke of Wellington appears to have almost always deployed his columns before attacking.

COLURES (*αἱ κόλουροι, colūri*). The term originally applied to any great circles of the sphere passing through the poles, but came at last to mean only the circles which also pass through the equinoxes and the solstices, which are distinguished as the equinoctial and solstitial colures. These terms are now of very little use, as the fact of a star being upon either circle is attended with no remarkable phenomenon. Astronomers would describe a star on the equinoctial colure as having either no right ascension, or twelve hours of right ascension, according as it is on the vernal or autumnal half of the circle; and a star on the solstitial colure as having either six hours or eighteen hours of right ascension, according as it is on the summer or winter side of the heavens. If we say that the sun is on the equinoctial colure at the quarter-days of March and September, and on the solstitial colure at those of June and December, we rather elucidate the term colure than derive information from it.

The solstitial colure passes through the poles of the ecliptic also, and might be called an ecliptic colure; but the other circle, which passes through the equinoxes and the poles of the ecliptic, has no distinct name, and would be best described as the circle from which celestial longitude is reckoned.

COLZA, OIL OF. The seeds of the *Brassica campestris oleifera* yield by expression about 39 per cent. of a yellow oil, which possesses a specific gravity of ·9136, and solidifies at 21° Fahr. It is a mixture of the glycerine compounds of two acids, namely *Brassic acid* ($C_{44}H_{43}O_4$). The other acid resembles *oleic acid*, but does not seem to be identical with it. Colza oil is used both for lamps and in cookery.

COMA, a Greek word (κῶμα), signifying profound sleep; a morbid condition of the brain, attended with loss of sensation and voluntary motion, the patient lying as if in deep sleep.

It can scarcely be considered a primary or idiopathic disease; it is rather symptomatic of that condition of the brain which, when in sufficient intensity, produces apoplexy. If it be regarded as a positive disease, it must be considered as a milder form of apoplexy. It exists in different degrees of intensity; several of which degrees, as they are attended with some variety in the symptoms, and are dependent on some modification of the pathological condition of the brain, so they have acquired distinct names. When there is a state of mental and physical torpor, indicated by an almost constant tendency to sleep, and great inaptitude for muscular exertion; when the patient is sensible only as long as he is strongly excited, and as soon as the external stimulus is withdrawn, lapses into a state of forgetfulness, the affection is called Lethargy. When no distinct consciousness returns, however the patient may be roused or stimulated, though there still remain some indication of feeling on the application of mechanical irritation, as on being pricked or pinched, the affection is called Carus. But when the insensibility is so great that the patient indicates neither sensation nor feeling, whatever mechanical stimulus be applied, this state is often called, by way of eminence, Coma. This comatose state invariably accompanies apoplexy; and, as has been stated, coma, when intense, passes into apoplexy.

The abolition of sensation and voluntary motion (animal functions), which constitutes coma, is always attended with a greater or less disturbance of the organic functions. The circulating system is disordered; the pulse at one time is slow and full, and at another quick and small. The respiration is laborious, and is commonly preternaturally slow. The power of generating animal heat is almost always diminished, the skin being cold and clammy; though there are cases in which the temperature is elevated somewhat above the natural standard. The countenance is usually pale and sunk; the pupils dilated, but in the worst cases contracted; the position of the body is supine; in the worst cases there is a constant tendency to sink down in the bed; the limbs are motionless; and the evacuations, if not wholly retained, which is usually the case, are passed without consciousness.

In coma there is an exhaustion or suppression of the sensorial powers, in other words, an abolition of the cerebral functions. This state of the nervous is always attended with a morbid condition of the vascular system. There is either a congestion of the capillary blood-vessels, occasioning obstructed circulation of the blood through the brain, or there is too rapid and violent a flow of blood through the cerebral vessels; or an inflammatory condition of the blood-vessels; or an extravasation of blood, or an effusion of serum into the cerebral substance. In addition to its disordered motion, there is also sometimes a depraved quality of the blood. There is reason to believe that to some morbid change in the constitution of the blood, the coma incident to bad types and advanced states of fever is mainly owing.

The morbid condition of the brain, on which coma depends, may be induced by any of the causes which have been enumerated as constituting the predisposing and exciting causes of apoplexy. [APOPLEXY.]

COMA BERENI´CES (Constellation), the hair of Berenice, placed among the stars by the astronomer, Conon, in memory of Berenice, the wife of Ptolemy Euergetes. (B.C. 246.) The legend is, that she had dedicated this hair to Venus, in case of her husband's safe return from Asia, and that it disappeared from the temple in which it was placed, and was never seen again till found in the starry heavens, where it now is, close to the tail of the Lion, and passing the meridian about an hour before Arcturus. [BERENICE.] Geminus attributes the constellation to Callimachus, who mentions it, as do Catullus and Pliny. Ptolemy does not place the stars now belonging to this constellation by themselves, but in the tail of the Lion; and Hyginus makes no separate mention of it. It was constantly mentioned by writers on the sphere, but not figured or catalogued separately, as far as we can find, till the time of Tycho Brahé.

The constellation Coma Berenices will be found shut up in the triangle formed by the three bright stars, Arcturus, β Leonis, and α Canum Venaticorum. It contains no stars of conspicuous magnitude.

COMB MANUFACTURE. Combs are generally made of a thin plate of wood, horn, tortoise-shell, ivory, bone, or metal, which may be either flat or curved, having one or two of its edges indented with narrow slits, which divide the substance of the comb into long, fine, pointed teeth. Combs employed in the woollen manufacture are described in the article relating to that subject. Curry-combs, used in dressing horses, consist of a number of iron plates notched on one edge to form saw-like teeth, and attached by the other edge to an iron back, in parallel lines, so as to form an instrument the action of which is between that of a scraper, a comb, and a brush.

In the mode of cutting and shaping the plates of which combs are formed there is little call for remark; but in the act of comb-cutting much ingenuity has been called into exercise. The hand-method is by means of a double saw, consisting of two separate fine saws, placed parallel with each other, and adjusted to such a distance as to embrace a tooth of the required fineness between them. These two saws are so arranged that while one cuts into the comb to the full depth required, the other cuts only about half that depth; by this contrivance the uniformity of the comb is secured; because, while the deeper saw is completing the first cut, the shallower one is forming the commencement of the second; and when, on the completion of the first cut, the deep saw is put into the second cut to complete it, the shallower one immediately commences a third. The cuts thus formed are subsequently enlarged and rendered smoother by means of a very thin wedge-shaped file, which also points the teeth. With such accuracy may these operations be performed, that delicate ivory combs, with from fifty to sixty teeth in an inch, are produced in this way. Though this method of comb-cutting is still practised, a superior and much quicker mode by means of circular saws and revolving cutters for pointing the teeth has been long in use.

By the above-described modes of comb-cutting all the material of the interstices between the teeth, is lost or destroyed; but by the operation known as the *parting* of combs such loss or waste of material may be avoided in the manufacture of combs of tortoiseshell, horn, or any other tough material; two combs being, by this process, made out of one piece, the teeth of one being cut, by the pressure of chisel-like instruments, out of the interstices of the other. Mr. Lyne's machine, for this purpose, is worked by the alternating action of a lever handle. The piece of tortoiseshell or horn is secured upon a traversing carriage, which is capable of motion in a direction perpendicular to that of the teeth of the comb. This carriage is made hollow, to receive an iron heater, the heat of which softens the horn, and thereby renders it more easy to cut. Between each movement of the carriage the cutter, which is a chisel equal in breadth to the length of the intended teeth of the comb, is brought down with sufficient force to cut completely through the horn or tortoiseshell. As the teeth are not required to be perfectly parallel, but in a slight degree wedge-shaped, the successive cuts of the chisel must incline a little obliquely, first in one direction, and then in the other, for which provision is made by an arrangement for alternately changing the position of the cutter during its descent. A pair of very narrow chisels mounted at right angles with, and at the ends of, the long cutter, serve, by their alternate descent, to connect each pair of cuts at their converging extremities, so as to detach the ends of the teeth. In Mr. Rogers's machine for the same purpose, everything is effected by the continuous turning of a winch, which, by means of a crank, works a double cutter, the two chisels of which are capable of adjustment according to the size of the teeth, while the screw for moving the bed or carriage is turned by means of a cog-wheel upon its axis, working into another on the axis of the winch. The extent of motion between each operation of the cutter is regulated by varying the relative sizes of these cog-wheels.

Among recent novelties in comb-making is Mr. Griffith's curious patent, in 1852, for "galvanic combs," of which the teeth are alternately of copper and zinc, while the handle is hollowed into a chamber for containing a roll of flannel moistened in acid solution. The inventor seems to expect a beneficial galvanic action by combing the hair with this apparatus. A more promising novelty is the application of the very tough substance called vulcanised india-rubber [CAOUTCHOUC MANUFACTURES] as a material for combs.

COMBAT, SINGLE. [DUEL.]

COMBINATION LAWS. The laws known by this name were repealed in 1824. Till then any combination of any two or more masters, or of any two or more workmen, to lower or raise wages, or to increase or diminish the number of hours of work, or quantity of work to be done, was punishable at common law as a misdemeanour: and there were also thirty-five statutes in existence, most of them applying to particular trades, prohibiting combinations of workmen against masters. The Act passed in 1824 (5 Geo. IV. c. 95) repealed all the statute and common law against combinations of masters and of workmen; provided a summary mode of conviction, and a punishment not exceeding two months' imprisonment for violent interference with workmen or masters, and for combinations for violent interference; and contained a proviso with regard to combinations for violent interference, that no law in force with regard to them should be altered or affected by the Act. But all the common law against combinations being repealed by the Act, this proviso was considered as of no force; and the Act also went beyond the intentions of the framers in legalising combinations unattended with violence for the purpose of controlling masters in the mode of carrying on their trades and manufactures, as well as peaceable combinations to procure advance of wages or reduction of hours of work. The Act was passed after an inquiry into the subject by a committee presided over by Mr. Hume, which reported to the House the following among other resolutions:—

"That the masters have often united and combined to lower the rates of their workmen's wages, as well as to resist a demand for an increase, and to regulate their hours of working, and sometimes to discharge their workmen who would not consent to the conditions offered to them; which have been followed by suspension of work, riotous proceedings, and acts of violence.

"That prosecutions have frequently been carried on under the statute and the common law against the workmen, and many of them have suffered different periods of imprisonment for combining and conspiring to raise their wages, or to resist their reduction, and to regulate their hours of working.

"That several instances have been stated to the committee of prosecutions against masters for combining to lower wages, and to regulate the hours of working; but no instance has been adduced of any master having been punished for that offence.

"That it is the opinion of this committee that masters and workmen should be free from such restrictions as regard the rate of wages and the hours of working, and be left at perfect liberty to make such agreements as they may mutually think proper.

"That therefore the statute laws which interfere in these particulars between masters and workmen should be repealed; and also that the common law, under which a peaceable meeting of masters or workmen may be prosecuted as a conspiracy, should be altered."

Immediately after the passing of this Act a number of widely organised and formidable combinations arose in various trades and manufactures for the purpose of controlling the masters as to the way in which they should conduct their business; and the extent to which the Act had repealed the common law being doubtful, and the Act having clearly gone beyond the resolutions on which it was grounded in legalising combinations, Mr. Huskisson, then President of the Board of Trade, moved early in the session of 1825 for a committee to consider the effects of the Act 5 Geo. IV. c. 95; and a committee was appointed with Mr. (afterwards Lord) Wallace, then Vice-President of the Board of Trade, for its chairman. This committee recommended the repeal of the Act of the previous session, and the enactment of another; and in consequence of their recommendation the 6 Geo. IV. c. 129, was passed, which is the Act now in force relative to combinations.

This Act repealed the 5 Geo. IV. c. 95, and all the statutes which that Act had repealed. It relieved from all prosecution and punishment persons meeting solely to consult upon rate of wages or hours of work, or entering into any agreement, verbal or written, on these points. And it provided a punishment of not more than three months imprisonment, with or without hard labour, for any one using violence, or threats to make a workman leave his hiring, or return work unfinished, or refuse to accept work, or belong to any club, or contribute to a common fund, or pay any fine for not belonging to a club, or contributing to a common fund, or refusing to conform to any rules made for advance of wages or lessening of the hours of work, or regulations of the mode of carrying on any business, and for any one using violence to make any master alter his mode of carrying on his business.

By the Act 6 Geo. IV. c. 129, therefore combinations of masters and workmen to settle as to rate of wages and hours of labour are made legal and freed from all punishment; but the common law remains as it was as to combinations for otherwise controlling masters. Although, therefore, workmen may conspire together not themselves to work under certain wages, they must carry out their object by lawful means, and cannot intimidate or prevent masters from employing, or workmen from taking employment, at any wages those other workmen may agree for. (Reg. *v.* Rowlands, 2 Den. C. C. 364.)

By 9 Geo. IV. c. 31, assaults in pursuance of a combination to raise the rate of wages are made punishable by imprisonment and hard labour.

COMBINATIONS AND PERMUTATIONS. By the word combination is usually meant any selection which can be made out of a number of different objects without reference to the order in which they are placed; while by a permutation is meant a combination in which different orders of position are to be considered as constituting a specific difference. Thus $a\,b\,c\,d$, $a\,c\,b\,d$, $d\,a\,c\,b$, are all the same combination of four out of the alphabet, but different permutations of four. The investigation of questions relating to combinations, &c., is the principal mathematical part of the theory of probabilities, and was first considered in detail, with reference to that science, by James Bernouilli and Montmort (see Library of Useful Knowledge: 'Probability'); but the common rules had previously found their way into arithmetical treatises. The enormous number of different arrangements of which objects are susceptible, even when their number is not large, drew early attention to the subject. We shall give some of the most simple rules, and a help to calculation for high numbers.

I. The number of permutations having x in each, which can be made out of X things, is the product of x terms of the series,

$$X, X-1, \quad X-2, \quad X-3, \text{ \&c.}$$

Thus, out of 10 things, there are 10 × 9, or 90 permutations of two; 10 × 9 × 8, or 720 permutations of three; 10 × 9 × 8 × 7, or 5040 permutations of four; and so on. Finally, the number of different arrangements which the whole ten will admit of, say the number of changes which can be rung on ten bells, is

$$10.\ 9.\ 8.\ 7.\ 6.\ 5.\ 4.\ 3.\ 2.\ 1. \quad \text{or } 3{,}628{,}800.$$

II. When the whole number of things, X, contains a which are alike of one sort, b which are alike of another sort, &c., the total number of arrangements of the whole is not the product of $X, X-1$, &c., down to 1, but that product divided by the product of 1, 2, 3. . . . up to a, then by that of 1, 2, 3. . . . up to b, &c. This result can be most easily formed by striking out common factors from the numerators and denominators.

III. In the last case, the number of permutations of x out of X being required, no simple rule can be given, but each case must be solved by itself. For instance, how many permutations of three can be formed out of

$$a \quad a \quad a \quad b \quad b \quad c.$$

(1.) All being different, 3. 2. 1. or 6. (2.) Where a is repeated twice, we have 6. (3.) Where a is repeated three times, one only. (4.) Where b is repeated twice, we have 6. In all, 19.

IV. The number of combinations of x things out of X, *all different*, is

prod. of x terms of $X, X-1, X-2$, &c.
divided by
prod. of x terms of 1, 2, 3, &c.

Thus out of 10 things, the number of combinations of four is 10. 9. 8. 7. divided by 1. 2. 3. 4, or 210. The best way of arriving at this result is by destroying common factors, which shows it to be 5. 3. 2. 7. Observe also that we may shorten this process, when x is greater than the half of X, by finding out, not how many selections can be taken, but how many remainders can be left. Thus the number of combinations of 25 out of 30, is the same as the number of combinations of 5, for 25 can only be taken in as many ways as 5 can be left.

V. The number of combinations of x things out of X, any repetition being allowed, is

prod. of x terms of $X, X+1, X+2$, &c.
divided by
prod. of X terms of 1, 2, 3, &c.

VI. The number of ways in which n places may be filled up from x

letters, allowing any letter to be repeated in all or or any of the places, is x^n, or the product of $x, x, x, \ldots .$ (n factors in all). This is the number of permutations of n out of x, allowing repetition.

VII. The number of ways in which n different letters can be distributed into x boxes, all possible modes of distribution being equally allowable, is x^n.

VIII. The total number of combinations of all sorts out of x things, from one at a time up to all together, both inclusive, is 2^x, or 2. 2. 2. . . . (x factors in all) diminished by 1. Thus out of 4 things, there are $2^4 - 1$, or 15 different sections: they are

a b c d, b c d, a c d, a b d, a b c, a b, a c, a d, b c, b d, c d,
a, b, c, d.

Among the curiosities of this subject, it will suffice to mention the following: The number of all possible arrangements of letters, repeated or not, and capable of being pronounced or not, up to words of 24 letters, is of the following order of magnitude: Take a million of millions; repeat it a million of million times: the result is between 1391 and 1392 millions of such numbers. As an instance of the manner in which the dropping of consonants and confusion of vowels may permit possible alterations of spelling, M. de Mairan computed that the word *Hainaut* might be spelt in 2304 different ways, so as to be pronounced in the same way by as many different Frenchmen, or very nearly so.

The most useful proposition in the higher part of the theory of combinations is the reduction of the formula 1. 2. 3. . . . . $(x-1)\,x$ to a very close approximation, which can be easily calculated by logarithms. It affords at the same time a useful lesson to those who have not studied mathematics at all, or very little; we have seen ignorance comport itself with laughter more than once at the idea of the preceding product being found by employing the proportion which the circumference of a circle bears to its diameter. But let $\pi = 3{\cdot}141593$ be this proportion; $\epsilon = 2{\cdot}718282$, the base of Napier's logarithms: then we have

$$1.2.3.\ldots\ldots(x-1)\,x = \sqrt{2\pi x}\left(\frac{x}{\epsilon}\right)^{x} \text{ very nearly.}$$

which is a little too small, but the error is only about the $12x$-th part of the whole: less than 1 per cent. even when x is so low as 10. The expression can easily be calculated by logarithms. Tables of the logarithms of this product will be found at the end of the article 'Theory of Probabilities,' in the 'Encyclopædia Metropolitana.' For an instance of the computation, see the Library of Useful Knowledge: 'Examples of Arithmetic,' &c., p. 45.

COMBINING PROPORTION. [Atomic Theory.]

COMBINING VOLUME. [Atomic Volume.]

COMBUSTIBLE. In its more restricted and usual sense, this term signifies a body which is capable of combining with oxygen, with the evolution of so much heat as to become luminous or incandescent. [Combustion.]

COMBUSTION is a term usually restricted to describe the phenomenon that ensues when chemical action is sufficiently intense to produce light and heat. The burning of coal, wood, paper, candles, oil, or coal-gas are familiar illustrations of combustion. Less common, but more brilliant, instances of combustion are seen in the explosion of gunpowder, or fireworks, or in the burning of steel-wire, charcoal, or phosphorus in oxygen gas.

In the examples of combustion above alluded to, the action lies between the burning body on the one hand, and pure or diluted oxygen on the other; and inasmuch as our world is enveloped in an atmosphere of which the most important constituent is oxygen, it follows that all ordinary instances of combustion are owing to the rapid oxidisation of bodies at a high temperature. It would be wrong, however, to suppose that the word combustion expresses no other actions than those indicated. Many substances burn equally well in atmospheres from which oxygen is excluded altogether, and in some cases even burn more readily than they would under similar circumstances in pure oxygen. For instance, when the metals arsenic or antimony are finely powdered and thrown into an atmosphere of chlorine, they instantly ignite, and burn with evolution of light and heat; in fact, literally undergo combustion.

Combustibles, and *supporters of combustion* or *non-combustibles*, are terms used to designate two distinct classes of substances. Air, oxygen, chlorine, &c., are non-combustible, that is, in the common acceptation of the word; they do not burn, but they support the combustion of other substances, such as wood, coal, &c., which latter are called combustibles. The phraseology is, however, purely conventional, and only applicable so long as the circumstances under which it is applied remain the same. For instance, common coal-gas burns in atmospheric air, and under these circumstances the gas is called the combustible and the air the non-combustible or supporter of combustion. But change the conditions, fill a jar with coal-gas, introduce a jet of common air and ignite the latter, perfect combustion will then go on at the jet: the air may now with equal propriety be said to be the combustible and the gas the non-combustible, for the gas just as much supports the combustion of the jet of air as in the former case the air supported the combustion of the jet of gas; in fact, both are equally combustible, and both equally support the combustion of each other. In like manner a jet of mercury vapour is combustible in an atmosphere of chlorine, and a jet of chlorine is combustible in an atmosphere of mercury. In these and other similar instances the chemical action between the two bodies at their line of contact with each other, is sufficiently intense to produce light and heat, and consequently it is at that line that the phenomenon of combustion ensues.

Spontaneous combustion is combustion that is set up between two bodies at common temperatures, without any application of artificial heat. Thus, the burning of arsenic and of antimony in chlorine, previously referred to, are examples of spontaneous combustion. In kindling a lucifer-match friction is necessary to produce a temperature at which the exposed phosphorus will ignite; but a piece of phosphorus, exposed to the direct rays of the sun on a warm day, will inflame spontaneously. Tow or cotton waste, moistened with oil and exposed to the air, frequently undergoes spontaneous combustion, on account of the attenuated state of the oil produced by the fibre being a condition favourable to the chemical action of the oxygen of the air upon it; on this account great care should be taken in factories where oily machinery is cleaned with cotton waste, to prevent the accumulation of materials of that description.

The spontaneous combustion of the human body is a subject that properly belongs to the past century; nevertheless, as some ignorant people at the present day believe that excessive and long-continued drinking of ardent spirits sets up a condition of system under which spontaneous burning of the body may ensue, it may be as well to notice here that, before the causes of combustion were investigated, it was customary when any person was found burnt to death and the origin of the fire could not be discovered, to assume that combustion had occurred spontaneously. The hypothesis has, however, long since been found to be untenable, and, amongst intelligent persons, is now only held by a few who have not taken the trouble to acquaint themselves either with the laws of heat or the causes of the phenomenon of burning.

The term combustion is sometimes used to describe certain chemical actions in which heat is evolved but no light. Thus the heat of the body is sometimes spoken of as being caused by the combustion of the carbon of the blood with the oxygen of the air. Occasionally, the word is used to denote particular chemical actions where not only no light but even no sensible heat is evolved; thus, the decay of animal and vegetable matter is said to be due to slow combustion. It is, however, far more convenient to speak of such as phenomena of oxidation, and restrict the term combustion to the meaning given to it at the commencement of this article.

COMEDY. [Drama.]

COMENAMIC ACID. [Meconic Acid.]

COMENIC ACID. [Meconic Acid.]

COMETARY BODIES. [Comets.]

COMETS. This term has been applied to bodies of a nebulous aspect which occasionally appear in the heavens, accompanied in the more conspicuous cases by a long train of light called the *tail*. The principal part of a comet's structure, in contradistinction to the last-mentioned appendage, is denominated the *head*. The outline of the head is hazy and ill defined; hence the origin of the term *comet* (*κομήτης*, from *κόμη*, hair). The head gradually increases in brightness towards the centre, where it assumes a planetary aspect. In some instances it exhibits a small bright central point, bearing a resemblance to a star. This point is called the *nucleus*. The head of a bright comet is usually shrouded in a paraboloidal envelope of light, the prolongation of which forms the tail. The tail is turned in the direction opposite to the region in which the sun is situate. Its outline is gently curved, being convex on the side towards which the comet is travelling. This remarkable appendage frequently extends over a considerable arc of the heavens, imparting a grand and mysterious aspect to the object with which it is connected. Nor is the length of the tail merely apparent; on the contrary, it not unfrequently extends to an enormous distance in space. Thus, for example, the tail of the great comet of 1843 attained a maximum length of 150 millions of miles; while the tail of the great comet of 1858, at the time of its greatest development, did not certainly fall short of 50 millions of miles in length.

The tail, however, must not be considered as forming an essential part of the structure of a comet. Multitudes of bodies of this class have been observed in modern times, which exhibited merely a round nebulous mass of light without the slightest vestige of a tail. Such bodies are generally visible only by the aid of the telescope; but even in some instances of comets of conspicuous magnitude, no trace of a tail has been discovered. For example, the comet of 1585, observed by Tycho Brahé, is said to have exhibited neither tail nor coma, but appeared perfectly round like a planet. ("Planè rotunda extitit; nec ullam caudam aut barbam in unam magis quam in aliam partem portendebat."[*]) Cassini relates a similar fact with respect to the comets of 1665 and 1682.

The appearance of a great comet in the heavens has in all ages strongly attracted the attention of mankind. During the earlier periods of history, bodies of this class were generally contemplated with superstitious dread as omens of divine displeasure, and were regarded as the precursors of some calamity to the human race. Even in the present day this opinion is prevalent among the ruder nations of the earth. The intelligence brought by the Overland mail respecting the terror caused throughout Egypt and India by the great comet of 1858, must be fresh in the recollection of every reader; and we may easily infer from this circumstance what must have been the impression produced on the still ruder tribes of Central Africa by the same mysterious object during the course of its rapid passage towards the southern hemisphere. The ancient philosophers failed to arrive at any just conclusions respecting the nature or movements of comets. According to Aristotle, comets are merely bodies of terrestrial origin, which are generated in the upper regions of the atmosphere. This opinion seems to have been generally entertained by astronomers down to the time of Tycho Brahé, who, by a discussion of the observations of the comet of 1577, finally succeeded in demonstrating that it must have been situate beyond the moon's orbit. Henceforward comets assumed their true place as bodies of celestial origin. It still remained to discover the nature of the paths which they described in the heavens, and to unfold the laws of their movements. Tycho Brahé imagined that comets move in straight lines; and Kepler seems to have entertained the same opinion. Hevelius was the first who conjectured that the path of a comet might be curvilinear; and Doerfel (1681) showed that the comet of 1680 actually described a parabola having the sun in the focus.

---

[*] Epist. ad Landgrav. p. 13.

It was reserved for the immortal Newton to discover the real nature of the movements of comets, and to demonstrate that, like the planets, they are mainly regulated by the attractive force of the sun. In the course of his researches on the principle of gravitation, this great philosopher had found that a body which receives an impulse in free space, and is subjected to the attractive force of the sun, will necessarily revolve in a conic section having the sun in the focus. The orbit actually described by the body *may* be either a circle, an ellipse, a parabola, or an hyperbola, but it *must* be one or other of those curves. By a rigorous investigation, founded on Flamsteed's observations of the comet of 1680, Newton discovered that the orbit of that body was a parabola having the sun in the focus. He moreover succeeded in demonstrating that the radius vector of the comet described around the sun equal areas in equal times, conformably to Kepler's second law of the planetary movements. Nor did his researches stop here: he also invented a method by means of which it would be possible from three observations of a comet to determine the elements of its orbit. In this investigation, he supposed the species of orbit described by the comet to be a parabola. His opinion was, that all such bodies revolve in elliptic orbits of great excentricity; but according to the doctrine of conic sections, the curvature of a very excentric ellipse does not sensibly differ from that of a parabola. He therefore adopted the parabolic assumption, which has the advantage of facilitating the solution of the problem.

Newton's method for determining the orbit of a comet, supplied the means of ascertaining *all* the elements if the orbit was a parabola; and all the elements except the major axis if the orbit was elliptic. In regard to the latter supposition, the adoption of which, as already mentioned, accorded with Newton's views, the author of the 'Principia' remarked, "I leave their axes and times of revolution to be determined from the comparison of comets which return in the same orbits after long periods." ('Princip.' lib. iii., prop. xii, 1st edit., 1687.)

Halley, who was one of the earliest supporters of the theory of gravitation, resolved to reduce to practice Newton's ideas on the theory of comets. He accordingly collected together all the recorded observations of those bodies extending down to the year 1700, and with incredible labour calculated the parabolic elements of their orbits in every instance wherein trustworthy data were available for such a purpose. The comets whose orbits were thus calculated amounted to twenty-four in number. They appeared in the following years:—

1337
1472
1531
1532
1556
1577
1580
1585
1590
1596
1607
1618
1652
1661
1664
1665
1672
1677
1680
1682
1683
1684
1686
1698

A comparison of the orbits of the comets of 1531, 1607, and 1682, clearly indicated to Halley that they referred to the same comet. This will readily appear from the following statement of their elements, extracted from Halley's table:—

	Comet of 1531.	Comet of 1607.	Comet of 1682.
Longitude of ascending node	49° 25′	50° 21′	51° 16′
Inclination of orbit . .	17° 56′	17° 2′	17° 56′
Longitude of perihelion .	301° 39′	302° 16′	302° 52′
Perihelion distance, . . that of the earth being 1	0·567	0·586	0·583
Perihelion passage . .	Aug. 24	Oct. 16	Sept. 4
Distance from perihelion to ascending node . .	107° 46′	108° 5′	108° 23′
Motion	Retrograde	Retrograde	Retrograde.

Upon comparing the intervals between two consecutive perihelion passages, it will be found that while for the comets of 1531 and 1607 the interval amounts to 76 years and 53 days; the corresponding interval for the comets of 1607 and 1682 amounts to only 74 years and 323 days. The difference between the two intervals amounts to 1 year and 95 days, or somewhat more than 15 months. But according to the theory of gravitation, a body revolving in an elliptic orbit around the sun in virtue of the attractive force of the latter, ought to return to its perihelion at successive intervals of equal magnitude; or, in other words, ought to perform its successive revolutions in equal times. Halley, however, did not fail to perceive the origin of this apparent discordance. He remarked, in fact, that the disturbing action exercised by the larger planets upon the comet could not fail to accelerate or retard the passage of the perihelion, as the case might be, and would thereby derange the equality in the times of revolution which would otherwise ensue. He found that in the summer of 1681, when the comet was approaching the perihelion, it passed so close to the planet Jupiter that it must have been powerfully disturbed by that body, and he clearly perceived that the effect of such a disturbance would have been to retard the arrival of the comet in the perihelion.

Adopting the interval which elapsed between the perihelion passages of 1531 and 1607, the comet ought to return to the perihelion in November, 1758; on the other hand, the adoption of the corresponding interval between 1607 and 1682 would fix the passage of the perihelion in the month of August, 1757. Halley very sagaciously inferred, from a rough estimation of the effect which would be produced by the disturbing action of Jupiter (for in his time there existed no methods for rigorously calculating the amount of such perturbations), that the comet would not be visible before the end of 1758, or the beginning of 1759; and he appealed to posterity not to lose sight of the fact, that if the comet should really return about the year 1758, the prediction of such a result was due to an Englishman.

The 'Astronomiæ Cometicæ Synopsis,' containing Halley's researches on Comets, was published in the 'Philosophical Transactions' for 1705, and again at the University press at Oxford, and also in an English translation, published in London in 1705, which was reprinted in 1706, in the 'Miscellanea Curiosa.' It was again reprinted in the second edition of Gregory's 'Astronomy;' in an English edition of the same work, 1715; in Le Monnier's 'Theory of Comets;' and was finally left for publication in an augmented form by Halley himself, and was published with his 'Astronomical Tables,' in 1749.

During the period which elapsed between the publication of Halley's researches on cometary orbits, and the time announced for the return of the comet of 1682 to the perihelion, an important step had been made in the application of analysis to physical astronomy. Methods for solving by an approximative process the problem of planetary perturbation were invented, independently of each other, by Euler, Clairaut, and D'Alembert, and were successfully used in computing the inequalities of the moon's motion. As the time fixed by Halley for the return of the comet to the perihelion drew nigh, the subject of its motion, which was calculated to exercise an important influence on the Newtonian theory of gravitation, naturally excited a lively interest throughout every country in Europe. Clairaut undertook the arduous task of computing the effects of planetary perturbation. He was assisted in his calculations by Lalande, who had just commenced his astronomical career, and also by Madame Lepaute, the wife of a well-known watchmaker of the day. The principal disturbing bodies in this case were Jupiter and Saturn. It was found that both planets tended to retard the passage of the comet through the perihelion. According to Clairaut's calculations, he found that the comet would be retarded 518 days by the action of Jupiter, and 100 days by the action of Saturn. Taking these circumstances into consideration, he found that the time of revolution would be 76 years, 211 days; and since the comet had previously passed the perihelion on the 14th of September, 1682, it followed that the next passage of the perihelion would take place on the 13th of April, 1759. Clairaut, however remarked that the omission of many small quantities, which was unavoidable in the treatment of so intricate a question, might cause the real time of the comet's passage of the perihelion to differ as much as a month from the calculated time.

The comet was first observed on the 25th of December, 1758, by Palitsch, an amateur astronomer of Saxony. It passed through the perihelion on the 13th of March, 1759; the time was consequently within the limits assigned by Clairaut. Having revised his calculations, the French geometer found that the error in the computed time amounted to only twenty-two days.

The return of this comet, conformably to the results of calculation, established beyond doubt the truth of Newton's theory of comets, and added fresh lustre to the renown of Halley, by whose name it has since been justly designated. Before proceeding to give some account of the circumstances connected with its perihelion passage in 1835, we shall present the reader with a brief statement of some of the more remarkable comets recorded in history.

371 B.C. In this year there appeared a comet of great splendour, which is alluded to by Diodorus Siculus and also by Aristotle. The former of these writers states that the phenomenon was supposed by the inhabitants of Greece to have presaged the destruction of the Achaian cities, Helix and Buris. According to Aristotle, the tail extended over a third of the heavens, or in other words, over an arc of 60°.

134 B.C. Justin states that there appeared in this year a splendid

comet, which continued visible 70 days. The tail is said to have covered a fourth part of the heavens, and occupied four hours in rising.

43 B.C. In this year, during the celebration of the games held in honour of Venus, a great comet appeared at Rome, which was visible before sunset. This celestial prodigy was supposed to have some connection with the departed soul of Julius Cæsar, whose assassination had shortly before occurred.

389 A.D. There appeared a comet, which is said to have almost rivalled Venus in brightness. The tail, which was of immense length, was curved like a scimitar. The apparition of so extraordinary a phenomenon excited universal terror.

891 A.D. Contemporary European writers allude to a great comet which appeared in this year. In the Chinese annals, wherein allusion to it is also to be found, it is stated that the tail was 100° in length.

1106. A great comet appeared, which was visible over all Europe. The tail is said to have resembled a fiery beam. According to Matthew Paris, it was visible in the day-time.

1264. This year was distinguished by the apparition of a magnificent comet, which is alluded to by several European writers, and is also mentioned in the Chinese annals. The tail is said to have attained a length of 100°.

1402. Two comets of extraordinary splendour appeared in the course of this year. The first became visible in the beginning of spring, and towards the close of March was so bright as to be visible in the day-time. The second comet of the year was not less conspicuous than the first, if we are to believe the statements of contemporary writers. The tail is said to have extended from the horizon to the zenith. It is stated, also, as in the case of the first comet, to have been visible in full daylight.

1456. A magnificent comet was visible throughout all Europe. The tail is said to have been 60° in length. The apparition of the phenomenon excited universal terror, in consequence of its being simultaneous with the capture of Constantinople by the Turks. With the view of averting the evil influence of its presence, Pope Calixtus II. ordered prayers to be offered up in all the Western churches; he also, in a famous bull, anathematised at once the Turks and the comet. It has been satisfactorily established in modern times that this was one of the early apparitions of Halley's comet.

1472. The comet of this year was undoubtedly the most splendid of the century. Towards the end of January it was visible in full daylight. In Europe Regiomantanus observed it. In China its successive positions with respect to the stars were also carefully recorded.

1531. An early apparition of Halley's comet. Observed in Europe by Peter Apian, at Ingoldstadt. An account of this apparition is also to be found in the Chinese annals.

1532. A comet appeared this year, which is stated by Cardan to have been visible in full sunshine.

1556. Apparition of a great comet, which has been supposed by some astronomers to be identical with the comet of 1264.

1577. The comet of this year is memorable in history from having furnished the data which enabled Tycho Brahé to demonstrate that the regions traversed by cometary bodies in general lie beyond the moon's orbit.

1607. An apparition of Halley's comet. The phenomenon was observed on the Continent by Kepler and Longomontanus, and in England by the celebrated mathematician, Hariot. The head is said to have equalled in size the planet Jupiter, but to have shone by a pale and watery light. The tail, which was of a very conspicuous brightness, was about 7° long.

1618. The third comet of this year was one of the most splendid of which history makes mention. Longomontanus states that the tail was 100° long.

1652. Apparition of a conspicuous comet, which is minutely described by Hevelius.

1664-5-8. Each of these years was distinguished by the apparition of a comet of considerable brightness.

1680. The comet of this year is, for several reasons one of the most remarkable of ancient or modern times. It was first seen by Godfrey Kirch, at Coburg in Saxony, on the 14th of November. After its passage of the perihelion on the 20th of December, it shone with great splendour, the tail appearing in some places to extend over an arc of 90°. This comet approached nearer the sun than any other comet recorded in history, with the exception of the great comet of 1843. It has been already stated that the observations of this comet furnished the data by means of which Newton was enabled to demonstrate that the orbits of comets are conic sections, having the sun situate in their common focus.

1744. This was the most brilliant comet of the 18th century. It was discovered at Haarlem by Klinkenberg, on the 9th of December, 1743. On the 7th of February the tail was 20° in apparent length. On the 1st of March, when the comet passed the perihelion, it was seen in full daylight. Remarkable physical changes were observed to occur in the head of this comet, on the occasion of its approach to the perihelion.

1759. An apparition of Halley's comet.

1769. This comet is memorable for the immense tail by which it was accompanied. Its passage of the perihelion took place on the 8th of October. On the 10th of September its tail appeared at Paris to be 60°. According to Pingré, the apparent length of the tail in tropical countries measured 97°.

1807. The comet of this year was very conspicuous to the naked eye. It was first discovered at Castro Giovanni in Italy, on the 9th of September, by Parisi, an Augustine monk. The passage of the perihelion occurred on the 19th of the same month. This comet was carefully observed by Sir William Herschel, who, in a paper published in the 'Philosophical Transactions of the Royal Society' for 1808, has recorded many interesting facts respecting it.

1811. The first comet of this year is in many respects one of the most remarkable of modern times. It was discovered by M. Flaguerges, at Viviers, on the 26th of March. The passage of the perihelion took place on the 12th of September. From that time till the end of the year it formed a very conspicuous object in the heavens, the effect being enhanced by the circumstance of its apparent path lying so near the North Pole that it always remained above the horizon. It was last seen in Siberia, by Wisniewski, a Russian astronomer, on the 17th of August, 1812.

1835. An apparition of Halley's comet.

1843. One of the most splendid comets recorded in history. It was seen with the naked eye, close to the sun, in Italy, the Cape of Good Hope, and America, on the 28th of February, the day of its passage of the perihelion. In some places the tail was observed to extend over an arc of 65°. It generally disappeared from observation about the beginning of April. This comet is remarkable for having approached nearer the sun than any other comet of modern times.

1853. A very fine comet appeared in the autumn of this year. Throughout Europe it was distinctly visible to the naked eye shortly after sunset.

1858. The comet discovered by Donati on the 4th of June in this year, is one of the most splendid of which history makes mention. It first became generally visible to the naked eye on the 5th of September. The passage of the perihelion took place on the 30th of that month. The comet attained its greatest slendour about the 10th of October. The tail then appeared to extend over an arc of about 40°. The comet ceased to be visible in Europe about the 20th of October, but it continued to be observed by Mr. Maclear at the Cape of Good Hope till the beginning of March in the following year.

Theory of the Movements of Comets.

The theory of the movements of comets resolves itself into two great subjects of research. One of these relates to the determination of the orbit of a comet from a definite number of observed positions, supposing it to revolve in a conic section around the sun; the other takes cognisance of the effects of planetary perturbation upon its motion. Newton's method for determining the elements of a comet's orbit was founded on the hypothesis of its revolving in a parabola. His opinion indeed was, that all comets revolve in very elongated ellipses; but he remarked, that in any of such cases the orbit near the perihelion does not deviate sensibly from a parabola. By supposing the path of the comet to be parabolic, the investigation of its elements is considerably simplified; but even with this assumption the problem is one of the most difficult in astronomy. It is plain, also, that the parabolic hypothesis cannot assign the major axis of the orbit, nor consequently the time of revolution. Newton, as already stated, remarked that the time of revolution might be found by comparing the intervals which elapsed between the apparitions of comets having the same parabolic elements. For this purpose, it is necessary to form a catalogue of the elements of all those comets the orbits of which have been computed; then, when a new comet has been observed, and its parabolic elements calculated, a reference to the catalogue will serve to indicate whether it has been observed on any former occasion; and if the newly calculated elements should thus turn out to be identical with those of any comet in the catalogue, the interval between the passages of the perihelion will give the time of revolution, supposing the two apparitions to be consecutive. In this way Halley determined the time of revolution of the comet which bears his name; and the same mode of ascertaining the periodicity of a comet is, in consequence of its easy application, constantly practised in the present day. The method most commonly used for computing the parabolic elements of a comet is one invented by the German astronomer Olbers, towards the close of the last century.

It is plain that the determination of the elements of a comet's orbit upon the parabolic hypothesis, is subject to the defect of not giving the major axis by direct investigation. In order to ascertain this element, it is necessary that the comet should have been observed at two consecutive passages of the perihelion. Nay, it may happen that, although the comet has been observed on more than one occasion, the apparitions may not be consecutive; and yet there exists no criterion by which a definitive conclusion on this point may be arrived at. Geometers have accordingly investigated methods for computing the elements of a comet's orbit, independently of any hypothesis with respect to the species of conic section in which it may be revolving. In this branch of research, Laplace and Gauss have laboured with eminent success. According to the method devised by the latter geometer, the six elliptic elements of a comet's orbit may be derived from three (in some cases four) observed positions of the body.

When a comet has once been discovered, three observed positions generally suffice, by the aid of Olbers's method, for ascertaining the parabolic elements of its orbit. If the places calculated from these elements satisfy all the subsequent observed places of the comet within the limits of the errors of observation, or if the observations can be satisfied by any possible correction of the original elements, it may be concluded that the comet revolves in an orbit which is sensibly parabolic. But if the observed places exhibit a systematic deviation from the corresponding results assigned by the parabolic elements, an indication is thereby afforded that the comet really moves in an ellipse or an hyperbola, and the orbit may be investigated *de novo* by means of Gauss's method. In this way the six elliptic elements of a comet may be at once obtained, by a process founded on merely three observed positions of the body.

The earliest general method for computing the effects of planetary perturbation on the movements of comets is due to Lagrange. The process devised by that geometer is founded on the application of mechanical quadratures to the theory of the variation of elements. The orbit of the comet is divided into a number of distinct sections, and the influence of planetary perturbation upon the elements is separately computed for the individual arcs. In applying this process to each arc, fresh elements are obtained which are employed in the computations of the arc immediately following. In regard to many comets, the influence of planetary perturbation is sensible only in the vicinity of the perihelion, and in such cases it is only there that the application of the method becomes necessary. It may be remarked that Lagrange's theory of cometary perturbation has served as the basis of all subsequent researches on the subject.

Periodic Comets.

§ (1) *Comets which have returned to their perihelia since the establishment of their periodicity.*

Halley's Comet.—An account has already been given of the circumstances connected with the perihelion passage of this famous comet in 1759. The next return to the perihelion occured in the year 1835. In 1812, the Academy of Sciences of Turin proposed the investigation of its perturbations as the subject of a prize. Damoiseau, an eminent French geometer, was on this occasion the successful competitor. He found that the comet would pass through the perihelion on the 4th of November, 1835.

In 1829 M. De Pontécoulant obtained the prize of the Academy of Sciences of Paris, for his researches on the same subject. The result of his first investigation indicated that the comet would pass the perihelion on the 7th of November, 1835; but on subsequently taking into account the disturbing action of the earth, and employing more accurate values of the masses of the other disturbing bodies, he found that the passage of the perihelion would take place on the 16th of November.

The perturbations of the comet on the occasion of the same perihelion passage, also formed the subject of elaborate investigations by Rosenberger and Lehmann, two German mathematicians. Rosenberger found that the comet would pass through the perihelion on the 11th of November; according to Lehmann the passage would take place on the 26th of the same month.

It was expected by astronomers that the comet would become visible about the beginning of August. This conjecture received a satisfactory confirmation. The comet was first discovered on the 5th of August, at the Observatory of Rome, by MM. Dumouchel and De Vico. Towards the end of September it became visible to the naked eye. It attained its greatest brilliancy about the middle of October. The head then resembled a star of the second magnitude. The tail exhibited an apparent length of about 20° in the countries of Northern Europe, but in southern climates it was observed to extend over an arc of 30°. The comet was not much seen in the northern hemisphere after the middle of November, having been shortly afterwards lost in the sun's rays. Early in the following year it was seen at the Cape of Good Hope, by Sir John Herschel and Mr. Maclear, and continued to be observed till the 12th of May.

The most complete investigation of the elements of the comet, founded on all the most trustworthy observations made in 1835-6, is due to Westphalen, a German astronomer of great promise, who shortly afterwards died at an early age. In order to exhibit the accordance which existed between theory and observation in this instance, we subjoin the elements of the comet as assigned respectively by Pontécoulant and Westphalen.

	Pontécoulant.	Westphalen.
Passage of the perihelion, M. T. Greenwich . .	1835, Nov. 15·01	1835, Nov. 15·95
Longitude of the perihelion	304° 31′ 42″	304° 31′ 32″
Longitude of the ascending node	55° 10′ 15″	55° 9′ 59″
Inclination	17° 44′ 58″	17° 45′ 5″
Excentricity . . .	0·9672807	0·9673909
Mean distance . . .	18·00008	17·99190

It has been already mentioned that the comet of 1456 was an apparition of Halley's comet. The discovery of this fact is due to the French astronomer Pingré. It has been recently ascertained by the late M. Edward Biot, that a conspicuous comet was observed in China in the year 1378, and M. Laugier has established beyond doubt that this was also an apparition of Halley's comet. The following are the times of revolution corresponding to the passages of the perihelion which have been deduced from the recorded observations:—

	Years.
1378—1456	77·58
1456—1531	75·21
1531—1607	76·15
1607—1682	74·91
1682—1759	76·49
1759—1835	76·68

The mean of these periods is 76·1 years. The deviations from this result represent the effects of planetary perturbation.

Encke's Comet.—This comet, as in the case of the famous comet of Halley, had been observed on several occasions of its return to the perihelion, before its periodicity was established. On the 26th of November, 1818, a comet was discovered by Pons at Marseille, the parabolic elements of which were soon afterwards found to resemble those of comets observed in 1805, 1795, and 1786. M. Encke was induced by this circumstance to investigate an elliptic orbit for the comets, and he found the time of revolution to be somewhat more than 1200 days. In 1822, on the occasion of its next return to the perihelion, it was rediscovered by M. Rumker, at Paramatta, in New South Wales. Upon tracing back its motion it was found to be in reality identical with the comets of 1805, 1795, and 1786, but a comparison of the earlier with the more recent perihelion passages seemed to indicate that the time of revolution was gradually becoming shorter. Professor Encke was induced in consequence to suspect the existence of a resisting medium, and adopting such an hypothesis, he calculated beforehand the perihelion passage of 1825. The results were found to present a satisfactory agreement with those derived from observation, and on every subsequent occasion of the comet's return to the perihelion, its motion has been successfully computed beforehand by Professor Encke, on the supposition of a resisting medium. The following table, extracted from a paper by Professor Encke, exhibits the gradual shortening of the time of revolution, as indicated by observation. This remark does not apply to the perihelion passages corresponding to the periods 1786-95, 1795-1805, and 1805-19, which were not observed, and are therefore necessarily the results of calculation.

Year of Perihelion Passage.	Time of Revolution in days.
1786	
1789	1212·79
1792	1212·67
1795	1212·55
1799	1212·44
1802	1212·33
1805	1212·22
1809	1212·10
1812	1212·00
1815	1211·89
1819	1211·78
1822	1211·66
1825	1211·55
1829	1211·44
1832	1211·32
1835	1211·22
1838	1211·11
1842	1210·98
1845	1210·88
1848	1210·77
1852	1210·65
1855	1210·55
1858	1210·44

These results indicate that the times of the successive revolutions are gradually shortening at the rate of about $\frac{11}{100}$ths of a day, or somewhat more than two hours and a half. No other comet has hitherto offered any evidence of a similar shortening of the time of revolution. The existence of a resisting medium cannot therefore be considered as established beyond doubt.

It might be supposed that the effect of a resisting medium would be to *lengthen* the time of the comet's revolution, rather than to shorten it as observation indicates. It is true, indeed, that the *direct* effect of such a resistance is to retard the orbital motion of the comet, and *so far* to prolong the time of revolution; but on the other hand, this diminution of the tangential motion allows the central body to act with greater efficacy in drawing the comet towards the centre. Now, according to the theory of central forces, the nearer a body approaches the centre of force the less must be the time of a complete revolution.

The following are the elements of this comet corresponding to the perihelion passage of 1858:—

Mean longitude	157° 59′ 18″
Ascending node	334° 28′ 34″
Mean anomaly	6° 1′ 48″.0
Inclination	13° 4′ 15″.0
Longitude of perihelion	157° 57′ 30″
Mean daily motion	1074″.05

Available for 1858, Oct. 18·5, Berlin mean time and mean equinox.

Biela's Comet.—This comet was discovered on the 27th of February, 1826, by Biela, an Austrian officer residing at Josephstadt, in Bohemia. Parabolic elements of its orbit were shortly afterwards calculated, and the results are found to bear a strong resemblance to the elements of comets observed in 1805 and 1772. This circumstance induced Gambart, the director of the observatory of Marseille, and Clausen, assisting astronomer at the observatory of Altona, simultaneously to compute elliptic elements of the comet's orbit. The results obtained by those two astronomers presented a satisfactory agreement with each other, and represented the observed places of the comet much better than the elements originally computed. The time of revolution was found to be nearly 6·6 years. Professor Santini of Padua computed the effects of planetary perturbation for the next return to the perihelion. By a discussion of the observations made subsequent to the discovery of the body, he found that it passed through the perihelion on the 18th of March, 1826, and that the corresponding time of revolution was 2455·176 days. Computing, then, the disturbing forces of the Earth, Jupiter, and Saturn, he found that the effect of their combined influence would be to shorten the time of revolution by 10·023 days, and that the comet would consequently pass through the perihelion on the 27th of November, 1832. It is a curious fact, that this comet, a little before its arrival in the perihelion, passes through the descending node of its orbit at only a very short distance from the earth's orbit. Great fears of a collision of the two bodies were consequently entertained, when it was announced as the result of astronomical calculation, that at the instant of the passage of the comet through its descending node on the 29th of October, the earth would be travelling in the same region. However, an exact computation of the earth's motion relatively to the comet had the effect of dispelling these apprehensions; for it was found that, although the comet would pass from the north to the south of the ecliptic on the 29th of October, the earth would not arrive in the same heliocentric longitude before the 30th of November.

The comet, on the occasion of its re-appearance, was first perceived on the 23rd of August by the observers of the Collegio Romano at Rome. Its passage through the perihelion took place within a few hours of the time fixed by the calculations of Professor Santini. The next passage of the perihelion took place in 1839, but the circumstances of its motion being unfavourable for observation, the comet passed unperceived. The results of Professor Santini's calculations showed that the next perihelion passage would take place on the 11th of February, 1846. On this occasion the comet did not pass unobserved. It was re-discovered, independently, on the 28th of November by Professor Encke, at Berlin, and Signor De Vico at Rome. During the interval of its visibility it underwent a singular change, having separated into two distinct fragments which continued to travel together at a distance of 3′ or 4′ from each other. This singular phenomenon appears to have been first unequivocally observed on the 12th of January, 1846, by Lieut. Maury, of the Observatory of Washington, (U.S.). One of the comets was considerably fainter than the other. Both bodies were seen for the last time on the 16th of April, 1846. Professor Plantamour computed the elements of the orbit described by each comet, taking into account the perturbations produced by the Earth, Jupiter, and Mars. The places of the two bodies when computed from these elements, were found to agree very nearly with the observed places. Professor Plantamour determined the mutual distances of the two bodies, and obtained the following results:—

Date.			Mutual Distance.	
1846	February	10	149,820	miles.
,,	,,	17	153,530	,,
,,	,,	26	156,649	,,
,,	March	3	157,220	,,
,,	,,	16	155,790	,,
,,	,,	22	154,210	,,

The comet was again observed on its return to the perihelion in 1852. The appearance which it presented on that occasion continued to afford evidence of the disruption which it suffered in 1846, both fragments being still visible. Circumstances do not seem to have been favourable for its re-discovery at the time of the perihelion passage of 1859.

Faye's Comet.—On the 22nd of November, 1843, a comet was discovered by M. Faye, at the Royal Observatory, Paris, the observations of which it was found impossible to satisfy by a parabolic orbit. Dr. Goldschmidt was induced by this circumstance to compute an elliptic orbit for the comet, and obtained results which agreed very well with the observed motion. The time of revolution is 2718 days, or 7·44 years. The comet has been re-observed on the occasions of its return to the perihelion in 1851 and 1858.

Brorsen's Comet.—On the 26th of February, 1846, M. Brorsen discovered at Kiel, in Denmark, a small telescopic comet, which was speedily found to revolve in an elliptic orbit, the time of revolution being about 5·6 years. It was not observed on the occasion of the passage of the perihelion in 1851, but it was found at the next return to the perihelion in 1857.

D'Arrest's Comet.—This comet was discovered by Professor D'Arrest, at Leipsic, on the 27th of June, 1851. It was speedily found to revolve in an elliptic orbit, the period being about 6·4 years. The circumstances of the next perihelion passage were calculated by M. Villarceau, of the Imperial Observatory, Paris; and by the aid of an ephemeris, due to that astronomer, the comet was re-discovered at the Cape of Good Hope by Mr. Maclear, on the 5th of Decembe, 1857. The comet continued to be observed till the 18th of January, 1858. During the whole period of its visibility it presented a very faint aspect.

§ (2) *Comets which have been found to revolve in elliptic orbits, but which have not been re-observed since the discovery of their periodicity.*

A considerable number of comets in addition to those contained in the foregoing list, have exhibited traces of a deviation from parabolic motion, and elliptic orbits have in consequence been calculated for them, the results derived from which have been found to satisfy the observations with a greater or less degree of precision. We proceed to notice briefly the results relative to the periodic time which have been obtained for a few of the more interesting of those bodies.

Comet of 1680.—Halley was of opinion that this comet was identical with comets which appeared in the years B.C. 43, A.D. 531, and 1106; and he hence inferred a period of 575 years. Professor Encke, however, has found by an investigation, based upon all the recorded observations, that the most probable value of the periodic time is 8800 years; but he remarks that in consequence of the large probable errors of the data, the observations of the comet may be tolerably satisfied by an ellipse with a period of 805 years, or even by an hyperbolic orbit. The observations of Flamsteed and Newton alone indicate a period of 3164 years.

Lexell's Comet.—This comet was discovered by Messier in 1770. Astronomers having been unable to satisfy the observations by parabolic elements, an elliptic orbit was computed by Lexell, who found the periodic time to be somewhat more than five years. The comet was carefully searched for on the occasion of the next two expected returns to the perihelion, but it was not discovered in either instance, nor has any trace of it been ever since obtained. Lexell endeavoured to account for this curious circumstance by remarking that previous to 1770 the comet had always been invisible, but that having passed very close to the planet Jupiter in the year 1767, it was thrown into a new orbit, and rendered *visible;* and that, in 1779, having again approached very near to the same planet, it was thrown again into a new orbit, and thereby rendered *invisible.* The researches of Lexell were subsequently confirmed by Laplace, but Le Verrier has in recent times called in question some of the data on which they rest.

Comet of 1811.—The orbit of this famous comet has formed the subject of an elaborate investigation by Argelander, who found it to revolve in an ellipse, with a period of 3065 years. This result must be understood, however, as corresponding only to the time of the perihelion passage. Argelander has shown that the disturbing forces of the planets must exercise a very considerable influence on the time of the next perihelion passage. By computing the perturbations up to May, 1827, he found that the time of revolution would be shortened from that cause to the extent of no less than 177 years.

Comet of 1815.—This comet was discovered on the 6th of March, 1815, by the celebrated astronomer Olbers. Bessel subjected the observations to a thorough discussion, when he found the comet to revolve in an ellipse, with a period of 74 years. Taking into account the effects of planetary perturbation, which he found would accelerate its movement to the extent of two years, he finally ascertained that the comet would again arrive in the perihelion in the month of February, 1887.

De Vico's Comet.—On the 22nd of August, 1844, De Vico discovered at Rome a comet which was found to revolve in an elliptic orbit, with a period of about five and a half years. It was carefully searched for at the perihelion passages of 1850 and 1855, but in neither instance has it been discovered.

Peters' Comet.—This comet was discovered by Dr. Peters at Naples, in 1846, and was found by him to revolve in an elliptic orbit with a period of 12·85 years. According to this result the comet ought to have returned to the perihelion in the year 1859, but hitherto it has not been found.

Winnecke's Comet.—On the 8th of March, 1858, Dr. Winnecke discovered a comet at Bonn, which he found to revolve in an elliptic orbit with a period of 5·549 years. He also established its identity with a comet observed in the year 1819. Supposing it to have made seven revolutions since that year, the time of a complete revolution would be 5·541 years, a result agreeing almost exactly with that obtained by a direct investigation of the elliptic elements.

Donati's Comet.—The observations of this famous comet appear to be best satisfied by an elliptic orbit. According to Professor Stampfer of Vienna, the period of revolution is 2141 years. However, until the totality of the observations shall have been subjected to a complete discussion, it will be impossible to arrive at any definitive result on this point.

Number of Comets.

It is impossible to form any opinion with respect to the number of comets which are liable to visit our system. Multitudes of those bodies, whether from their faintness or the circumstances of their movements, will doubtless for ever elude observation. Arago gives the following enumeration of the number of comets whose orbits have been calculated down to the close of the year 1853 :—

7 apparitions of Halley's comet.
14 apparitions of Encke's comet.
6 apparitions of Biela's comet.
2 apparitions of Faye's comet.
46 apparitions of comets revolving in elliptic orbits, or of which two passages of the perihelion may perhaps have occurred.
151 apparitions of comets revolving in parabolic orbits.

The following statement of the progress of cometary discovery during the five years which have elapsed subsequently to the year 1853, will enable the reader to form an opinion with respect to the activity which pervades this department of astronomical science :—

Year.	Number of Comets discovered.
1854	3
1855	1
1856	0
1857	7
1858	6
	17

It is to be remarked that the foregoing list includes four re-discoveries of periodic comets, namely, the re-discoveries of Brorsen's and D'Arrest's comets in 1857, and of Encke's and Faye's comets in 1858.

Dimensions of Comets.

The head of a comet is frequently a body of immense magnitude. The following are some of the results which have been obtained by the aid of micrometric measurements :—

	Diameter of the Head.
The great comet of 1811	1,270,000 miles
Halley's comet (1836)	357,000 „
First comet of 1780	267,500 „
Comet of Lexell, 1770	204,000 „
Donati's comet	100,000 „

Sir William Herschel found the diameter of the envelope of the great comet of 1811 to be no less than 643,000 miles.

The nucleus of a comet, in many instances not distinguishable at all, is generally of inconsiderable dimensions. The following are some results of micrometric measurement :—

	Diameter of Nucleus.
Comet of 1799	373 miles
„ 1807	538 „
„ 1811	2637 „
Donati's comet (October 6, 1858)	800 „

The tail of a comet sometimes attains an enormous length, as the following numbers will show :—

	Length of Tail.
Comet of 1680	96,000,000 miles
Comet of 1769	38,000,000 „
Comet of 1811 (October 15)	100,000,000 „
Comet of 1843	150,000,000 „
Great comet of 1858 (Donati's)	51,000,000 „

Physical Constitution of Comets.

The substance of which a comet is composed appears to be of remarkable tenuity. This has been abundantly proved by the circumstance of the smallest stars being seen through their structure without undergoing any sensible diminution of light. Sir John Herschel, in a paper on Biela's comet, published in vol. vi. of the 'Memoirs of the Astronomical Society,' has mentioned a fact which affords a striking illustration of the translucency of cometic matter. The comet having passed over a small cluster of stars of the sixteenth or seventeenth magnitude, the appearance presented was that of a nebula, partly resolvable into stars. The most trifling fog would have effaced the stars; but in the present instance they still continued to be visible, although the cometic matter interposed between them and the observer must have been at least fifty thousand miles in thickness.

The question whether the nucleus of a comet is in any case a solid body has been often discussed, but no definitive conclusion has been arrived at. The passage of the nucleus of a comet over a star might be supposed to supply a useful criterion for deciding this point, but no instance of the actual occurrence of such a phenomenon has ever been satisfactorily established. Newton was of opinion that the nuclei of comets must necessarily be solid bodies, since otherwise they would in many cases be dissipated in space by the intense heat to which they are subjected on the passage of their perihelia.

But whether the nuclei of comets be solid or not, it is certain that their masses must be very inconsiderable. This is evident from the circumstance of their producing no sensible derangement in the motions of the planets, however near they approach them. In the year 1779 Lexell's comet passed through the middle of the system of Jupiter's satellites, but none of those bodies appeared to be in the slightest degree affected by its attractive force.

Allusion has been made to the great heat which many comets must undergo on their passage of the perihelion. The following table of perihelion distances will show how near comets in some instances approach the sun :—

Date of Apparition of the Comet.	Perihelion Distance.
1843	475,000 miles
1680	570,000
1689	1,900,000
1826	2,565,000
1847	3,990,000
1816	4,560,000

Newton found by calculation, that the comet of 1680, on its passage of the perihelion was subjected to a heat 2000 times greater than that of red-hot iron. The great comet of 1843, which approached nearer the sun than any other comet recorded in history, must have been exposed to a heat of still greater intensity. Laplace, availing himself of Black's beautiful discovery of the principle of latent caloric, considered that the heat abstracted by the cometic particles in the course of passing into the vaporous state would serve to moderate the effect of the solar heat at the perihelion, and upon this ground he concluded, that the nucleus of a comet is not necessarily a solid body.

When one of the more conspicuous comets is advancing towards the perihelion, it is seen to undergo a succession of changes in the head and tail. These singular phenomena, which are evidently due to the action of the sun, appear to have been first remarked by Hooke in the course of his observations of the comets of 1680 and 1682. The following extract from his observations of the comet of 1682 (an apparition of Halley's comet), will enable the reader to form some idea of the changes to which we refer. It is right to state that the comet passed through the perihelion on the 15th of September :—

"August 26. At seven in the evening I delineated the figure and shape of the comet, exactly like that I saw through my fourteen-feet telescope, which will appear more plain by the fifth figure than I can otherwise well express it.* It had a pretty bright round nucleus, and about that was an atmosphere of thinner light which was terminated towards the sun with a round figure. That part of this halo, or lighter atmosphere towards the sun, was not so bright or radiant as another kind of light which seemed to issue from the nucleus or star both ways at right angles with the axis through the sun, which lighter issuings bent into a kind of parabolic figure, within the former halo or atmosphere, and was terminated within it, and seemed to form, as it were, a second parabolical termination towards the sun, in the apex of which parabola was the bright nucleus, and this brighter parabolic line of light seemed as gross or thick as the nucleus itself. This issued on both sides, but that on the right hand, or the northernmost, was much more conspicuous; insomuch that that on the left hand, or towards the south, was to be seen but sometimes, but that on the other side was very plain and conspicuous, and seemed like a stream of flame blown out of a candle by a blowpipe, ascending or bending upwards, just as such a blown flame of a candle will do, if it be made by a gentle blast. This I remarked very carefully, to see whether I could find, by any succeeding observations, any alteration of the magnitude, figure, brightness, or position, in respect of the comet's axis. These two bright spoutings of flame or light turned or bent upwards from the sun, and after a short space seemed to unite into the axis or middle of the blaze, and form the shape of the outside of a flame of a candle tapering to a point: the fainter part also without it seemed to taper much in the same manner. I saw also several coruscations or flashings of the flame, shooting out to a great distance into the blaze."

Phenomena of a similar nature were remarked by Heinsius in the course of his observations of the great comet of 1744. In more recent times, Halley's comet (1835), and the great comet of 1858, exhibited analogous changes previous to their passage of the perihelion. It has been already stated that Halley's comet passed through the perihelion on the 15th of November. Previous to the 2nd of October, the appearance which it presented was that of a round nebulous disk, with a faint nucleus in the centre. On that evening, however, the nucleus became exceedingly bright, and there was seen to issue from it a cone of light, which first extended a short distance in the direction of the sun, and then bent back as if impelled by some intense force in the opposite direction. This outstreaming cone of light continued to be seen until the 22nd of October, subject however to violent changes when observed from night to night. It is worthy of remark that simultaneously with these changes the tail was observed to increase gradually in length. The phenomena observed during the apparition of the great comet of 1858, were of a still more complex nature than those which characterised any previous comet, but it would be out of place here to enter into any minute details. On the 16th of September there commenced a series of luminous emissions from the nucleus, which continued till the passage of the perihelion at the end of the month. These were followed by a succession of envelopes of a paraboloidal form surrounding the head, and which were seen in greater or less number at the various observatories throughout Europe and America till the disappearance of the comet about the 20th of October.

The development of the tail when a comet is advancing towards the perihelion affords also a striking indication of the action of the sun, although the mode in which it is exerted continues to be involved in great mystery. The following results of micrometric measures of the progress of the tail of the great comet of 1858, executed at the observatory of Harvard College, Cambridge, U.S., will furnish an apt illustration of our remark:—

---

* These drawings are given in Hooke's 'Posthumous Works.'

Date			Apparent length of Tail.	Absolute length of Tail.
1858	August	29	2°	14,000,000 miles
„	September	8	4	16,000,000 „
„	„	12	6	19,000,000 „
„	„	17	4	10,000,000 „
„	„	23	7	12,000,000 „
„	„	24	7	12,000,000 „
„	„	25	11	17,000,000 „
„	„	27	13	18,000,000 „
„	„	28	19	26,000,000 „
„	„	30	22	26,000,000 „
„	October	2	25	27,000,000 „
„	„	5	35	33,000,000 „
„	„	6	50	45,000,000 „
„	„	8	50	43,000,000 „
„	„	10	60	51,000,000 „
„	„	12	45	39,000,000 „
„	„	15	15	14,000,000 „

The shortening of the tail between the 12th and 17th of September is due entirely to the effect of moonlight. To the same cause may be partly attributed the change from the 10th to the 15th of October, but it is no doubt mainly due to the rapid diminution of the brightness of the comet.

Numerous theories of the origin of the tails of comets have been proposed from time to time, but as they are all open to serious objections we do not think that any useful purpose would be served by giving an account of them on the present occasion. It is plain from the observations of the more conspicuous comets, that the tail is fed by the matter raised from the nucleus by the action of the sun. There would appear to be in this case two forces acting upon the cometic particles, independently of the force of gravitation. First, we have indications of a force violently ejecting the particles to a short distance from the nucleus; and secondly, we have equally clear evidence of a repulsive force of great intensity directed upon the comet from the sun, and driving the particles so ejected to an immense distance in space. The most probable view of the nature of these powerful forces is that which attributes them to electrical agency, but no satisfactory theory of the subject has yet been advanced by any inquirer.

COMITIA. Comitium originally signified a place of meeting, as the name imports. Varro, 'De Ling. Lat.' l. v., s. 155. Plutarch ('Romulus,' xix.) says that the plain where the Romans met the Sabines, in order to agree on the terms of a treaty, was called "comitium," and Niebuhr, 'History of Rome' (i. 291, ed. 1851), in narrating the history of the union of the two towns of Roma and Quirium, and accounting for the steps by which the union was effected, mentions the old legend of a place of meeting for the Roman and Sabine kings and senates, called comitium from the fact of its lying between the Palatine and Capitoline hills. Whether it was intended to preserve a record of the old place of meeting, or was simply used as a topographical description must be left to conjecture. The word was retained and applied to a particular part of the Forum, where for many a day the remembrance of the old rivalry was preserved by the two statues of Romulus and Tatius that were erected in it. The plural "comitia" denotes general assemblies of the Roman people, convened by the constitutional authority of some magistrate, in order to enact or repeal anything by their suffrages. One set of comitia was named "calata," from the old word *calare*, to call or convene (A. Gellius, 15, 27), where the people were summoned to be witnesses to certain solemn acts, or certain things then announced to them.

There were three kinds of Roman comitia:—

1. *Curiata*, so called because the people met and voted in curiæ. Romulus, it is said, divided the whole Roman people into three tribes, and each tribe into ten curiæ, which were subdivided into decads, being, as Niebuhr contends, the same as houses, so that each curia containing 10 houses, the 3 tribes numbered 300 in all. Now, as no houses but those which composed the three ancient tribes were essential parts of the state, in consequence of which the patricians could boast that they alone (*gentem habere*) had a house (Livy x. 8), this division, so essential to the patrician order, was in close connection with it, and therefore, when the political importance of the plebeians rose, the curiæ sank and, except in the continued observance of their sacra, for some years after their political degradation, fell into oblivion. The word curiæ is derived from curare, to take care of or superintend civil and religious affairs (Varro, 'De L. L.' v. 165, and vi. 46); though another and somewhat plausible etymology is that which connects it with the Sabine word Quiris or Curis. (See Smith's 'Latin Dictionary,' *sub verbo.*) Each curia formed a separate community for the celebration of sacred rites, for which purpose a particular priest, called curio, was attached to each curia, and a decurio, or captain and burgess to each decad or house. But all the curiæ were under the superintendence of a curio maximus. A separate place which was also called curia, was assigned to each curia for performing its sacred rites. The members of a curia were called curiales.

There is some obscurity and doubt about the ancient constitution of the curiæ and comitia curiata. However, it seems certain, that the curiæ had the superintendence of sacred matters, that all the public power was united and centralised in the comitia curiata, and that the patrician order must have possessed a great preponderance in them. (See Niebuhr's 'Rome,' vol. i., 'on the Curies.') In these comitia laws were made or repealed, peace or war declared; (as to treaties of peace, however, see 'Dict. of Gr. & Rom. Antiq.' Comitia, p. 332 b), the affairs of the curiæ and gentes or houses decided, capital crimes judged, and the king as well as the other chief magistrates of the state elected. The place of meeting (comitium) was in the forum, and in its northern corner were the rostra. There was no fixed time for the meeting of the curiæ, but they met as business required, and were held in the presence and under the protection of the priests, their president being the king, or an interrex in the ante-republican times, and some high patrician magistrate, a consul, prætor, or dictator, under the Republic, while none but the populus or the patrician members of the curiæ had a right to take part in these assemblies.

Servius Tullius having instituted the comitia centuriata, and the plebeians becoming powerful through the comitia tributa, the comitia curiata gradually lost almost all political power. However they still passed enactments under the title of leges curiatæ, which, before the institution of the comitia centuriata, denoted every law made by the comitia curiata; but afterwards that term was limited to express a few political rights, still reserved to the latter comitia, particularly that of granting military power (*imperium*) to those magistrates who were elected in the comitia centuriata, which could only confer civil power (*potestas*). Finally, the political influence of the comitia curiata was reduced to a mere formality, and represented, in Cicero's time, by thirty lictors. Still, a shadow of the old institution was preserved in the continuance of the patrician comitia calata used principally for the adrogationes. Though their political power was lost, the curiæ retained their religious functions till the last times of the republic, and always elected the curio maximus and the flamens. Their number was never augmented, as was the case with the tribes. Before proceeding to the second class of comitia, a few words on the subject of a peculiar authority possessed by the comitia curiata will not be inappropriate, for a more full account of which the reader is referred to Niebuhr's 'Hist.,' vol. i. ch. 21. The election of the kings was, it is known, in the hands of the curies, but in addition thereto, to this body belonged the conferring the imperium (Cic. 'De Rep.' ii. 13): hence they not only could elect, but they could annul that election: the first it is said was done by the populus, the second by the senate or patres, and to effectuate that second decision, a law was passed by the patres, called by Cicero lex curiata de imperio, and by Livy, auctoritas patrum (Livy i. 17). The conclusion that Niebuhr draws from this identity of the auctoritas patrum, and the lex curiata de imperio is, that the comitia of the curies and the assembly of the patricians were identical.

2. *Centuriata.* Servius Tullius, according to tradition, in order to diminish the power of the patricians, and to elevate the plebeians without giving them any power, made a new division of the Roman people into six classes, which were subdivided into centuries or votes. There has been much dispute about this division and the number of the centuries; and the controversy scarcely admits of decision, as the ancient writers (Livius, i. 43, Dionys. Halicarn., 'Antiq. Rom.,' i. 19-22, and Cicero, 'De Republica,' ii. 22) are of different opinions. But the nature of the institution is not so doubtful. According to the more probable opinion (that of Dionys. Hal.), the 6 classes contained 193 centuries. The first class consisted of 18 centuries of knights and 80 centuries of those (*ditissimi*) whose fortune amounted to at least 100,000 ases; the second class (*ditiores*) contained 22 centuries, and consisted of those who possessed at least 75,000 ases; the third (*divites*) 20 centuries, and consisted of those who had a property of 50,000 ases at least; the fourth class (*mediocres*) 22 centuries, of those who possessed 25,000 ases at least; the fifth class (*modici*) 30 centuries, of those who possessed 12,500 ases; the sixth class contained but one century of capite censi, that is, persons counted by head and not by estates: they were also called proletarii, or ærarii.

According to this division the Roman people met in the comitia centuriata, in order to vote in centuries on public matters; that is, a decree of the assembly was made by counting the votes of the centuries. As the first class alone contained more centuries than all the other classes together, it may be said that, as Romulus had created an aristocracy of birth by his division of curiæ, so Servius Tullius created an aristocracy of fortune by his new division. In order to prevent that disadvantage, when the plebeians had obtained more power, the century which was to give its suffrages first was appointed by lot. The century upon which the lot fell was called prærogativa. The other centuries voted according to the order of their classes, and were called jure vocatæ. The decision by lot being regarded as a divine omen, the centuriæ jure vocatæ commonly followed the vote of the centuria prærogativa; and thus the power of the first class was balanced in some measure. A contest however sometimes arose whether a matter was to be decided in the comitia centuriata or tributa.

Every Roman citizen in the best sense of the words (*civis optimo jure*) had the right of giving his suffrage in the centuries. The magistrates who were competent to call these comitia were the consul, the prætor in the absence of the consul, and the dictator, or his representative the magister equitum. The magistrate who presided sat on the sella curulis. On holydays (*feriæ*) comitia were not lawful; the days on which they could be held were called dies comitiales. The place of meeting was the Campus Martius, where were placed the septa for the voters, or inclosures into which classes were admitted one after the other, the president's tabernaculum, and the villa publica for the augurs. Before the business began the auspices were taken, and if they were not favourable the meeting was deferred to another day; but if no obstacle appeared, the business was opened with the standing formula, *velitis jubeatis Quirites* (by reading either the names of the candidates, or the proposition of a law (*rogatio*). Originally they gave their suffrages aloud (*vivâ voce*), but afterwards by tablets, or ballot; which mode of voting was established by the leges tabellariæ, in order to secure the freedom of election. It was not till after a long contest, commenced by the tribune Gabinius, B.C. 140, that the plebeians obtained the protection of the ballot.

As the comitia curiata originally possessed the sovereign power, so, after the time of Servius Tullius, it came into the hands of the comitia centuriata.

In the first place all legislation belonged to these comitia, and the enactments made by them only were called leges (laws), being obligatory upon all the Romans. A *lex* differed both from a decree of the senate (*senatûs-consultum*), and from an enactment of the comitia tributa (*plebiscitum*), which only bound the respective estates of the patricians and the plebs. If a law was to be proposed to the comitia centuriata, it was to be promulgated (*promulgata*), that is, notice of it was to be given on three market days before the day of assembly. The proposed law being accepted by the people, which they expressed by the term "perferre," was, after being confirmed by oath of the people, engraved on a public tablet and deposited in the ærarium. See Ulpian, tit. i. s. 3, and D. 35, 2. 1.

Henceforward all magistrates, both ordinary and extraordinary, were elected at these comitia, as consuls, prætors, censors, decemvirs, and military tribunes. Those who sought for office appeared in a white toga (*toga candida*, and hence they were called *candidati*) before the people on three previous market-days. The candidate who was elected was proclaimed by the præco, or crier; and if this formality was not observed the election was null. Until the magistrate elect entered upon his office he was called "designatus."

The comitia centuriata were also the court for the decision of war, and probably for accepting and confirming treaties, as well as the court of the people (*judicium populi*), for judging public crimes (*crimina publica*) of a grave kind, which were immediately directed against the state or people; as for example, attempts upon the freedom of the people, attempts of individuals to seize on the sovereign power, insult to or the murder of a tribune. Such a crime, which was called crimen perduellionis, was different from the crimen majestatis. (Cicero, 'De Repub.' ii. 36; 'De Legit.,' iii., 4; 'pro Sext.,' 30, 34; and Heinecc., 'Antiq.,' iv. 18, 46, and 47.)

3. The *Comitia tributa* were the comitia wherein the Roman people met and voted according to tribes. The plebeians having acquired considerable power in the state, these comitia achieved their first important victory B.C. 471, by the Publilian law, which secured to them the right of electing the tribunes, and eventually the other inferior magistrates; while their second great power was gained by the law of Valerius Publicola, B.C. 449, which, giving them the right of originating measures, raised their decrees to the same position as a lex, being again extended by the Hortensian law, so that "Plebiscita omnes Quirites tenerent." Neither birth nor fortune gave advantage in these comitia, as was the case in the other comitia. Every Roman citizen who was classed or registered in a tribe was permitted to vote in them. The place of meeting was not fixed, but ordinarily it was the Campus Martius; sometimes also the forum or capitol, or Circus Flamininus. The same minute formalities with respect to the auspices were not necessary as at the comitia centuriata. The assemblies were called by a tribune, who also presided, if tribunes or ædiles were to be elected; but at elections of other magistrates, or if laws were to be made, consuls and prætors also might preside.

Soon after these comitia were established, all inferior magistrates, ordinary and extraordinary, were elected in them, as tribunes, ædiles, quæstors, proconsuls, and proprætors; the election of the pontifex maximus, and of various other religious functionaries, was made in these comitia. They also sat in judgment in certain inferior cases; but for capital punishments the comitia centuriata only had competent authority, and the trial of Coriolanus, as the story has come down to us, must be regarded as an anomaly and an illegal act.

It has been already mentioned that enactments made by the comitia tributa were called plebiscita, and at first bound only the plebeians. But as the power of the plebeians became enlarged by degrees, the plebiscita, after many contests between the plebeians and patricians, were made equal in effect to the leges, by the lex Hortensia, B.C. 288. (Gaius, i. 1.) From this time these comitia possessed the complete legislative power, thoroughly independent of the senate. Accordingly enactments for making war or peace, or granting a triumph, were frequently passed against the will of the senate.

In the later times of the republic, the management of the comitia became an important object both for ambitious aspirants to power, and for those who professed to maintain the rights of the people. Cæsar, after being made perpetual dictator, virtually concluded their authority by himself appointing consuls, and naming half of the other magistrates. Finally, the elections of the comitia became a mere formality.

(Sigonius, *de Antiq. Jur. Civ. Rom.* i. 17.; Nic. Gruchii, lib. iii. *de Comit. Rom. in Thes. Antiq. Rom.*, ed. Grævius, t. i. p. 531, seq.; Dr. Smith's *Dictionary of Greek and Roman Antiquities*, articles "Comitia," "Curiæ," "Lex," "Plebiscitum.")

COMMA, in Music (κόμμα), is the difference between two sounds whose ratio is 81 : 80; or, the difference between the major tone, C D ($\frac{9}{8}$) and the minor tone, D E ($\frac{10}{9}$). Practically considered, the comma is the ninth part of a major tone. Ptolemy thought so small an interval inappreciable: Salinas asserts the contrary. Maxwell ('Essay on Tune') agrees with the latter, and gives the following rule for tuning the comma: Obtain C, stopped as the octave to the open fourth string (on the violin), and the difference between that note and the same taken as the greater sixth below the first open string, must be a comma. We refer those who wish to go deeper into this matter to Smith's 'Harmonics.' But the clearest and fullest information on the subject is to be obtained from the 'Théorie Acoustico-Musicale' of M. Suremain-Missery.

COMMANDERY, a species of benefice attached to certain foreign military orders, usually conferred on knights who had done them some especial service. According to Furetière, these commanderies were of different kinds and degrees, as the statutes of the different orders directed. The name of commandery in the order of St. Louis was given to the pension which the king of France formerly assigned to twenty-four commanders of that order. The order of Malta had commanderies of justice, which a knight obtained from long standing; and others of favour, of which the grand master had the power of disposal.

In England, commanderies were the same amongst the Knights Hospitallers as preceptories had been among the Knights Templars, namely, societies of those knights placed upon some of their estates in the country under the government of a commander, who were allowed proper maintenance out of the revenues under their care, and accounted for the remainder to the grand prior at London. At the dissolution of religious houses, in the time of Henry VIII., there were more than fifty of these commanderies in England, subordinate to the great priory of St. John of Jerusalem. A few of these held productive estates, and had even the appearance of being separate corporations, so much so as to have a common seal; but the greater part were little more than farms or granges. The Templars' term of preceptory was as frequently used to designate these establishments as the term commandery. In Germany the provision for the vicars of a cathedral is also called a commandery. (Furetière, 'Dictionnaire Universel;' Tanner, 'Notitia Monastica,' edit. 1787, pref. p. xvii.; Dugdale's 'Monasticon Anglicanum,' last edit., vol. vi., pp. 786, 800.)

The title of commander has also been adopted to designate the second rank of the Knights of the Bath, who are Knights Commanders. [BATH, KNIGHTS OF THE.]

COMMENDAM, from "commenda," a term of the canon law, which, according to its original signification, was applied where the custody of a void ecclesiastical benefice was, during the avoidance, committed by the bishop or other superior to a person who was to discharge the spiritual duties attached to the benefice without meddling with the profits. The person to whose charge these duties were committed was said to hold the benefice *in commendam*. In time, this practice degenerated into an actual perception of the profits, and the device of holding livings *in commendam* was found by the ecclesiastics of the middle ages a useful method of evading the provisions of the canon law against pluralities. [BENEFICE.] By the law of England no benefice can be held *in commendam* without a licence from the crown. This prerogative has been most frequently exercised where the parson of a parish has been made bishop of a see, the revenues of which were insufficient to support the dignity of the station. For the only way to prevent the avoidance of a benefice by promotion to a bishopric, is to grant a licence to retain it *in commendam*, commonly called a *commendam retinere*. This licence is granted before consecration, or before confirmation, in the case of a translation; another kind of dispensation, called a *commendam capere* or *recipere*, enables a bishop to take a benefice after consecration or confirmation. The consent of the patron of the benefice was essential to the validity of a commendam.

Not only dignities and benefices, but headships of colleges and hospitals, might be granted *in commendam*, &c.

Licence to hold *in commendam* might be temporary or perpetual; but the learning on this subject has now become of little practical value; for by statute 6 & 7 Will. IV., c. 77, s. 18, it is enacted, that no ecclesiastical dignity, office, or benefice, shall be held *in commendam* by any bishop (unless he then held the same); and that every *commendam* thereafter granted, whether to retain or to receive, and whether temporary or perpetual, shall be absolutely void to all intents and purposes.

COMMENSURABLE. Two magnitudes are commensurable which have a common measure. The peculiar part of this subject belongs to INCOMMENSURABLES, THEORY OF, and PROPORTION, which see.

COMME'RCIUM EPISTO'LICUM (commerce of letters), a name which was at one time frequently given to published collections of letters, such as were common about the end of the 17th century and the beginning of the 18th. Thus we have the 'Commercium Epistolicum' of Wallis in the second and third volumes of his works (1693 and 1699); that of Kepler (though his name does not appear in the title-page), published in 1718; and that of John Bernoulli and Leibnitz, published in 1745.

But the name by itself is generally understood to apply to the celebrated collection published by the Royal Society in 1712, in vindication of their decision upon the dispute between Keill and Leibnitz as to the right to the invention of the Differential Calculus, or Method of Fluxions. We have not space here to enter upon the subject-matter of the quarrel itself, but only to give some account of the 'Commercium Epistolicum' [referring for the rest to FLUXIONS, METHOD OF].

In the year 1708, Newton and Leibnitz being then both alive, Keill, an astronomer, now better known by his concern in this matter than by his writings or discoveries, inserted in the 'Philosophical Transactions' (No. 317) an article in which he defended Newton against the editors of the Leipsic Acts, who had spoken of Newton's 'Quadratura Curvarum' as a secondary work in comparison of the previous writings of Leibnitz. He asserted that the method of fluxions was first invented by Newton, and that Leibnitz, changing the name and notation, had inserted it in the Leipsic Acts: his words will bear the construction that he conceived Leibnitz to be a plagiarist, but not that of his being an independent inventor. Leibnitz, on the receipt of this volume (March, 1711), complained of the accusation in a letter to Dr. Sloane (then secretary of the Royal Society); reminded him that on a similar accusation having been made a few years before by M. Fatio de Duillier, the Society and Newton himself had disapproved of it; pointed out the dishonourable stigma implied by Keill (whom he presumed to be innocent of all bad intention), and requested the interference of the Royal Society to induce him to disavow the intention of imputing fraud. Keill (in a letter to Dr. Sloane, May, 1711,) denied that he meant to charge Leibnitz with having known the science of Newton by name and notation; but asserted that Newton had explained his Fluxions in two letters to Oldenburg (then secretary of the Royal Society), which were transmitted to Leibnitz; and that the latter either did draw, or at least could have drawn, the principles of Differentials from thence. On this subject he wrote a long detail of what he considered to be the proof of his assertion. Leibnitz, in another letter (December, 1711), complains that the charge was now more open than before; that he and his friends had never contested the independent invention of Newton; and that he appealed to the Royal Society and to Newton himself. The Royal Society accordingly appointed a committee, which collected and reported upon a large mass of documents, consisting mostly of letters from and to Newton, Leibnitz, Oldenburg, Wallis, Collins, &c., &c. Their report was to the effect that Leibnitz was in London at the beginning of the year 1673, from which time to September, 1676 (when he visited London before returning to Hanover), he was in correspondence with Collins and Oldenburg; that when first in London, he was in possession of a differential method, which was no other than that of Mouton; and that he never mentioned any other till he wrote a letter of June, 1677, being a year after a copy of Newton's letter to Oldenburg, of December 10, 1672, had been sent to Paris to be communicated to him, and four years after Collins began to communicate the contents of that letter. Also that by a former letter of Newton, of June, 1676, it appeared that he had been in possession of his Fluxions five years before: that Leibnitz's method is in fact the same as that of Newton, with a difference of name and notation; finally, that Newton being the first inventor, Keill, in asserting the same, had been no ways injurious to Leibnitz. This report, preceded by a large mass of letters or extracts, appeared in the year 1712; and again with a 'Recensio,' &c., prefixed, and some other additions in 1722; this reprint was also issued with another title-page in 1725. It was translated into French, and was also published in a journal at the Hague. Leibnitz only protested in private letters against the injustice of the proceeding: he declared that he would not answer a reasoning so weak; and it appears moreover that he had on his mind an impression that the acrimony excited against him in England was political. He was in the service of the Elector of Hanover, the health of the queen was declining, and many of the men of science were Jacobites.

With regard to the 'Commercium Epistolicum,' and the Report attached, it is obvious that the final conclusion was not to the point. The question was not whether Newton was the first inventor, but whether Leibnitz had stolen the method. The committee did not attempt to prove that Leibnitz had received the letter which was sent to Paris to be sent to Hanover: nor do they formally venture to assert their belief that Leibnitz was a plagiarist; but, with a subterfuge wholly unworthy of them, they conclude that because Leibnitz might have seen Newton's letter, &c., which they could not prove, Keill did him no injustice in asserting the priority of Newton's invention—which was not the matter of complaint. Moreover, they published much of their evidence in the form of extract, and their omissions are not always justifiable. It does not appear on the face of the report itself that Leibnitz knew of the appointment of the committee, or had any opportunity of stating any objections he might entertain to its members, or of furnishing any documents relating to the question under consideration. There runs throughout the extracts a desire of proving Leibnitz guilty of more than they meant positively to affirm. The latter acted wisely in appealing to posterity; for though party feeling long adopted the conclusions of the Report in England, it is now nearly, if not quite, the opinion of those who study the matter, that Leibnitz really was an independent inventor. The contemporary supporters of Newton, and their followers down to the present day, have chosen to regard the committee as a *judicial* body, and their report as a *decision*. But this was not the case. The committee was avowedly counsel for Newton, though the form of their report gave countenance to the mistake just mentioned. Faulty as they were in more points than one, their unfairness was that of advocates, not of judges.

The part which Newton himself took in the matter at the time was not very well known till lately. In the first edition of the 'Principia' (1687), he stated (book ii. Scholium to Lemma 11) that ten years before (the Scholium must probably have been written in 1686 at the very latest) he had communicated *in cipher* a single sentence to Leibnitz as a key to what he informed him was a method of drawing tangents, &c., and that Leibnitz not only wrote in reply, that he had fallen upon a similar method, but actually communicated it, and that he (Newton) found it to be the same as his own, except in notation and symbols. No doubt it was upon the strength of this scholium that Leibnitz confidently appealed to Newton himself: and we might have imagined that the question of the date of this letter would have formed a part of the inquiry. But we cannot find it alluded to: the publication of the 'Principia' is mentioned in its proper place, without a word as to this scholium; nor can we find any allusion to it. We wish we could end here: but we are compelled to add, that this scholium was omitted by Newton in the third edition of the 'Principia' (1725), and its place supplied by another, in which the name of Leibnitz is not mentioned, but an account of what Newton had written to Collins in 1672 begins and ends in nearly the same words. But it must be remembered that between 1687 and 1725, Newton had suffered that illness which perhaps impaired the powers of his mind, and certainly altered his disposition, perhaps even his memory; for in a letter preserved by Raphson, February 26, 1715-16, he gives an account of the letter of Leibnitz differing in several particulars from the printed scholium.

The 'Commercium Epistolicum' will be found complete in Horsley's edition of Newton, accompanied by additional letters extracted from Raphson's 'History of Fluxions,' London, 1715. The appendix contains the additional letters.

An edition of the 'Commercium Epistolicum,' with valuable notes, and the most recent information, has been published by MM. Biot and Lefort, Paris, 1856, 4to. To what precedes we may add the following facts, recently established.

1. The reprint of 1722 contains some small additions and omissions, though it professes to be nothing but a reprint. Some of these alterations are important, and of a highly unfair character. ('Phil. Mag.' June, 1848.)

2. The letter actually sent to Leibnitz has been found among his papers at Hanover, and a draft of it in the archives of the Royal Society. It does *not* contain the mathematical part of Collins's letter of December, 1672, but only the description given by Newton of the character of his results. This makes little difference; because the mathematical part of Newton's letter contained nothing sufficient, and nothing but the like of what had been printed before; but the discovery convicts the committee of extreme carelessness on the most important point. ('Comp. Alm.' 1852.)

3. Sir D. Brewster, by his recent examination of Newton's papers, has found that Newton himself is fully responsible for the contents, both of the 'Commercium Epistolicum,' and the reprint. This has very often been denied.

4. It has recently been proved, both by internal evidence and by the Newton papers, that Newton himself, a fact always strongly denied by his supporters of this century, wrote the account of the 'Commercium Epistolicum,' which appears in the 'Phil. Trans.' No. 342 (1714-15.)

COMMINATION, THE OFFICE OF, a service in the Liturgy of the Church of England. It is called "A Commination or denunciation of God's anger and judgments against sinners," from the Latin word *comminatio*, a threatening or cursing. The Protestants at the Reformation introduced the reading of this comminatory service as a substitute for the ancient and still continued Catholic ceremony of sprinkling the head, and making the sign of the cross on the forehead with ashes, on the first day of Lent, hence denominated Ash Wednesday; but though it is ordered especially to be read on this day, the rubric adds,—"and at all other times as the ordinary shall appoint." From Archbishop Grindall's Visitation Articles, published in 1576, it appears at that time to have been used on four days in the year, namely, on Ash Wednesday and on the third Sunday before Easter, Whitsuntide, and Christmas. The origin and object of the service will be best explained by the following extract from its commencement. "In the primitive church there was a godly discipline that at the beginning of Lent such persons as stood convicted of notorious sin were put to open penance and punishment in this world, that their souls might be saved in the day of the Lord, and that others, being admonished by their example, might be the more afraid to offend. Instead whereof (until the said discipline may be restored again, which is much to be wished) it is thought good that at this time (Ash Wednesday) should be read the general sentences of God's cursing against impenitent sinners." The form of the commination seems to be derived from Deuteronomy xi. 26–30 and xxvii. 1–26, which was afterwards strictly obeyed, as related in Joshua viii. 33–34, in the solemn rehearsal of a series of twelve curses from Mount Ebal by the Levites, with a response to each by the people. It may be observed that in this commination, the church does not pray that the sinner may be cursed, nor do the people affirm the curse by replying amen. The acts are stated which are cursed by the law, and the people acknowledge its truth. The blessing with which the service concludes was not added until the last revisal of the Prayer Book.

COMMISSARY, an officer who is delegated by a bishop to act in a particular part of the diocese, to exercise jurisdiction similar in kind to that exercised by the chancellor of the diocese in the consistory court of the diocese. A comissary has, generally speaking, the authority of official principal and vicar-general within his limits. An appeal lies from his decisions to the metropolitan. In some dioceses there is a commissary court for each archdeaconry. The commissarial courts were established for the convenience of the people in parts of the diocese remote from the consistory court. A commissary must be learned in the civil and ecclesiastical law, a master of arts or bachelor of law, not under the age of twenty-six, and he must subscribe the Thirty-nine articles (Canon 127).

In Scotland the same classes of questions which in other parts of Europe were arrogated to the ecclesiastical judicatories came under the authority of the bishops' courts while the episcopal polity continued, and subsequently devolved on special judges, who were called commissaries. The four commissaries of Edinburgh constituted the Supreme Commissary Court, which had jurisdiction in questions of divorce, and of declarators of the existence or non-existence of marriage. The district commissaries had the administrative authority of confirming executors to persons deceased, a function resembling the granting of letters of administration in England. By 4 Geo. IV. c. 97, the functions of the provincial commissaries were vested in the sheriffs of the respective counties, who, before the passing of that Act, were usually appointed the commissaries of their districts. By 11 Geo. IV. and 1 Wm. IV. c. 69, the jurisdiction of the commissaries of Edinburgh was vested in the Court of Session.

COMMISSION, in military affairs, is the document by which an officer is authorised to perform duty for the service of the state.

Anciently, in this country, the regular mode of asembling the national army, either to resist an invading enemy, or to accompany the king on a foreign expedition, was by sending a royal command to the chief barons and the spiritual lords, that they should meet at a given time and place with their due proportion of men, horses, &c. properly equipped, according to the tenure by which they held their estates; and these *tenants in capite* appear to have appointed by their own authority all their subordinate officers. But commissions were also granted by our kings to individuals, authorising them to raise men for particular services; thus, in 1442, Henry VI. gave one to the governor of Mantes, by which the latter was appointed to maintain 50 horsemen, 20 men-at-arms on foot, and 210 archers, for the defence of that city. According to Père Daniel, the commission was written on parchment, and, that it might not be counterfeited, the piece was divided by cutting it irregularly, into two portions, of which, doubtless, each party retained one.

Commissions of array, as they were called, were also issued by the crown, probably from the time of Alfred, for the purpose of mustering and training the inhabitants of the counties in military discipline; and in the reign of Edward III. the parliament enacted that no person trained under these commissions should be compelled to serve out of his own county except in the event of the kingdom being invaded. Of the same nature as these commissions of array was that which, in 1572, when the country was threatened with the Spanish invasion, Queen Elizabeth issued to the justices of the peace in the different counties, authorising them to muster and train persons to serve during the war. Those magistrates were directed to make choice of officers to command bodies of 100 men and upwards; and such officers, with the consent of the magistrates, were to appoint their own lieutenants. This privilege of granting commissions to the officers of the national militia continued to be exercised by the lords-lieutenants of counties, the king having the power of confirming or annulling the appointments; and it was made law in the reign of Charles II. It appears, however, that before the Revolution, the lieutenants and ensigns were recommended for commissions by captains of the companies.

In the French service, between the reigns of Francis I. and Louis XIV., we find that the sovereigns reserved to themselves the nomination of the principal commanders only of the legions or regiments, and that the latter were permitted to grant commissions under their own signature and seal to the subordinate officers, who were charged with the duty of raising the troops and instructing them in the use of arms.

In the British regular army, as well as in the navy, all the commissions of officers are signed by the sovereign. In the navy, in the regiment of artillery, and in the corps of engineers and marines, the commissions are conferred without purchase; as also a large proportion of the commissions granted to officers of the line. Those cadets who have completed a course of military education in the Royal College at Sandhurst and pass successfully, are gazetted without purchase. Such is the case also with those who pass their examination before the Military Commissioners very well, and with the sons of officers who have fallen in the service, or in any case which the commander-in-chief may consider merits it. In other cases, gentlemen obtain leave to enter the army by the purchase of an ensigney, the prices of which, in the different classes of troops, are regulated by authority; and they proceed to the higher grades on paying the difference between the price of the grade which they quit and of that which they enter.

The commissioned officers of a battalion of infantry are as follow: Field-officers—colonel, lieutenant-colonel, and major. Regimental officers—captains, lieutenants, and ensigns. Staff-officers—chaplain, adjutant, quarter-master, and surgeon.

For a statement of the prices of commissions, see 'The Queen's Regulations and Orders for the Army.'

COMMISSION. [Agent; Broker; Factor.]

COMMISSIONERS, LORDS. [Assent, Royal; Admiralty.]

COMMISSIONERS OF BANKRUPTS. [Bankrupt.]

COMMITTEE, of either house of parliament, may be either of the whole House or of a certain number of the members selected from the rest. When the House resolves itself into a committee of the whole House, the Speaker in the Commons, or the Lord Chancellor or whoever else is the ordinary Speaker in the Lords, leaves the chair, and the Chairman of Committees, a salaried officer, being one of the members, who is appointed by the House at the commencement of of every parliament, takes his place. In the Commons the mace, which usually lies on the table, is at the same time placed under it. In a committee members are not restricted to a single speech on the question under consideration, but each may speak as often as he pleases. Another distinction in the Commons was, that the committee divided by the Ayes merely going to the one side of the room and the Noes to the other, instead of one of the two parties going out into the lobby, as in divisions of the House. But the modern practice of publishing the names having become general, there is now no practical difference between the two modes. By the standing orders or established practice of both Houses, there are certain subjects that can only be brought forward in a committee of the whole House. For instance, all measures relating to the Church must be so introduced; and in the Commons all propositions for the grant of money for the public service must be first made in such a committee, called a Committee of Supply; and all propositions for raising the money so granted, by taxes or loans, or otherwise, in another committee of the whole House, called a Committee of Ways and Means. No committee can consider of any matter except that referred to it by the House; nor can a committee adjourn; therefore, when the business lasts more than a day, a motion is made and agreed to that "the chairman do report progress, and ask leave to sit again;" and when the business is concluded, the chairman is directed to report the resolutions, or he may be directed to bring in a bill. No vote of a committee is of any force until it has been reported to the House, and the report received. The Committees of Supply, and of Ways and Means, always meet for the first time immediately after the commencement of the session, and are commonly continued very nearly to its close by leave to sit again being repeatedly granted by the House. Instructions directing, or otherwise to a certain extent controlling, their proceedings, are frequently issued to committees by the House, to which, of course, they are bound to attend. All public bills in both Houses are also considered in committees of the whole House, after the second, and before the third reading. Private bills cannot be introduced into either House, until the petitions of the parties interested for leave to bring them in have been referred to select committees; and every such bill is again referred to another select committee after the second reading. The members of select committees are commonly appointed by the open nomination of each, that is, in effect, by the vote of the House; but those of committees for trying contested elections in the House of Commons are appointed by secret ballot. The investigation of any subject whatever that is brought before parliament may be referred to a Select Committee, and the proceedings of such committees are usually conducted in public; but sometimes a Committee of Secrecy, which takes evidence and deliberates with closed doors, is appointed, when the public safety or other reasons are considered to make that precaution expedient. A committee is generally empowered to summon witnesses, and to call for papers; but no committee of either House can administer an oath. A witness can only be examined on oath at the bar of the House of Lords.

There are some instances in former times of all the members of both Houses meeting together, at the request of one of the Houses, and such a meeting is described as a Committee of the Lords and Commons. What is called a Joint Committee of the two Houses, composed of a certain number of members selected from each, was formerly not unusual. The time and place of meeting were always appointed by the Lords; and the practice was for that House to appoint only half the number of members appointed by the Commons. A joint committee had the power of examining witnesses on oath; a privilege possessed by the Peers, but not by the Commons. It had, however, no power to report anything more than the evidence taken by it, and as the numerical superiority of the members of the lower House gave them an advantage distasteful to the Lords, the custom has sunk into desuetude, and there has been no joint committee during the last century and a half. In cases in which a joint committee would formerly have been appointed, the method that has been taken is for separate committees to be appointed by the two Houses, with power to communicate with each other. (Hatsell's 'Precedents,' and J. E. May's 'Law, Privileges, Proceedings, and Usage of Parliament.')

COMMITTEE OF A LUNATIC. [LUNACY.]

COMMITTEE OF PUBLIC SAFETY, Comité de Salut Publique, the name given to a committee of members of the National Convention, who exercised a dictatorial power in France for about fifteen months, which is known by the name of the Reign of Terror. After the successful insurrection of the 31st of May, 1793, when the Mountain or terrorist party in the Convention gained the victory, by means of the armed multitudes of Paris, over their fellow-deputies of the Gironde party, Robespierre and his friends monopolised all the power of the Committee of Public Safety. "The committees concentrated itself at last in three of its members: Robespierre, who was the real chief, though half-concealed from view; and Couthon and St. Just. There was perfect unanimity among these three down to the moment of their fall; and there is reason to believe that they had resolved to perpetuate their power by establishing a supreme council of three consuls, in which Robespierre would have had the perpetual presidency, with the departments of justice, exterior, and finance; Couthon, that of the interior; and St. Just, the war department." ('Histoire pittoresque de la Convention Nationale,' par un Ex-Conventional, 4 vols. 8vo, Paris, 1833.) After a career in which every step was marked with blood, the national feeling revolted against such a tyranny, some of Robespierre's old associates, whom it is said he was about to sacrifice, impeached him before the Convention, and he and his few friends found themselves alone, without any military man to support them. Even in the Committee of Public Safety, Collot d'Herbois and Billaud Varennes turned against Robespierre. On the 9th Thermidor, July 28, 1794, Robespierre, Couthon, and St. Just were executed.

A reaction had now taken place in the popular opinion, which pursued the agents of the proscriptions at the bar of the Convention, when their former accomplices, being obliged to give them up, endeavoured to throw the whole blame upon them. Many of them were guillotined, and several of them, among whom were Barrière, Collot d'Herbois, and Billaud Varennes, were transported to Cayenne.

COMMODORE (*commendador*), in the royal navy, is the officer commanding a small number of ships of war, when detached for any particular service from the fleet. In the British navy, commodores are of two classes: Those of the first are distinguished by a red, broad, swallow-tailed pendant at the mast-head; those of the second class, by a blue one. The former are considered flag-officers, and rank and command next to a rear-admiral, and are allowed to change their broad pendant from one ship to another as occasion may require. The service rank of a commodore is equal to that of a brigadier-general in the army. The title is sometimes given to the senior captain in a fleet of merchant ships.

In the French service, the commander of a detachment of ships is called *Chef d'Escadre*; and in the time of Louis XIII. the commander-general of the fleet was so called when he had not the rank of admiral.

COMMON LAW. In its most general signification the expression common law denotes the ordinary law of any country; when used in this sense it is called *common*, as prevailing generally over a whole country, in contradistinction to *particular* laws, the operation of which is confined to a limited district. In this sense the phrase is used in many countries which have adopted the civil law. But in England the definition is scarcely applicable, the common law with us comprising many particular laws, confined to districts, such as the law of gavelkind, the laws of stannaries, and the laws of every manor in the country. For in English jurisprudence by the common law is understood that body of customs, rules, and maxims which have acquired their binding power and the force of laws in consequence of long usage, recognised by judicial decision, in contradistinction to the law contained in statutes now extant. The common law is therefore called, in early periods of our legal history, the "lex et consuetudo Angliæ," and at the present day the appellation is always used to denote the "lex non scripta," in opposition to the "leges scriptæ," or statutes. In addition to customs and usages, whose particular origin is unknown, many portions of the common law undoubtedly consist of statutes passed before the time of legal memory, namely, the beginning of the reign of Richard I., and which, though known historically to have been acts of parliament, have no authority as laws in that character, but derive their obligation from immemorial usage, recognised by judicial decision. The provisions of the common law are, however, quite as binding upon the subjects of England as acts of the legislature, being, as already said, impressed with the character of law by force of judicial decisions. In very early times the system of rules which composed the common law was probably wholly traditional. As civilisation advanced, the decisions of the superior courts of justice were recorded, and that became the authoritative evidence of such customs and maxims as formed part of the common law, in precise analogy to the rule of the civil law, that what the emperor had once judicially determined was to serve as a guide in all like cases for the future. In addition to these recorded judgments of the courts, technically called precedents, the treatises of learned men, called by Blackstone "the sages of the law," such as Bracton, Fleta, Britton, Staundforde's 'Pleas of the Crown,' and Coke's 'Commentary upon Littleton,' have long been acknowledged as depositories of the common law. Of the whole system the judges of the superior courts are the expositors; they declare the law by applying its rules and principles to cases which come before them for judgment; but they have no power to add to or vary the law itself.

Learned writers have indulged in much speculation respecting the origin of the common law of England, though Sir Matthew Hale says it is "as undiscoverable as the head of the Nile." It seems, however, to be well ascertained that the customs which in ancient times were incorporated with it, were of compound origin, and introduced at various times in conformity with the political vicissitudes of the country; some being Saxon, others Danish, and others Norman. It is also quite evident, from the adoption of the Roman terms of art and several Roman provisions, that many of the rules and maxims which the common law has adopted were derived from the civil law. The greater part of our modern mercantile law is unquestionably derived from that source. Again, many parts of the common law have gradually arisen from the necessary modification of its ancient doctrines and principles, in order to render them applicable to new states of society produced by enlarged commerce and advancing civilisation. From this cause some branches of our system of jurisprudence, and notably our law merchant, have wholly sprung into existence in modern times. The whole of the law of evidence for instance, now perhaps the most important part of our practical jurisprudence, has appeared as part of the common law so lately as the time of the Commonwealth. But perhaps the most remarkable instance of the flexibility of the common law, and its capacity of adapting itself to circumstances, is presented by the history of our trial by jury, which may be traced through all its gradations, from a rude kind of trial, in which the jury were merely witnesses called from the neighbourhood in order that they might declare the truth to the judge, to the present artificial system, where the jury themselves decide upon the truth of facts by the testimony of witnesses examined before them. On the other hand, many rules and provisions of the common law have wholly disappeared, having either become obsolete from disuse, or been gradually abrogated by decisions of the judges as they became inapplicable to the altered state of society. So great has been the alteration of the common law which these accessions and abstractions have occasioned, that it can scarcely be termed with propriety the same body of laws that it was 600 years ago, unless it be upon the principle upon which Sir M. Hale maintains its identity, namely, that the changes have been only partial and successive, whilst the general system has been always the same, "as the Argonauts' ship was the same when it returned home as it was when it went out, though in that long voyage it had successive amendments, and scarce came back with any of its former materials." (Hale's 'History of the Common Law;' Blackstone's 'Commentaries,' vol. i.; Reeve's 'History of the Law of England,' vol. i.; Hallam's 'Middle Ages,' vol. ii., on the origin of the Common Law.)

COMMON MEASURE, any magnitude which is contained an exact number of times in two other magnitudes. Thus in the case of numbers, 7 is a common measure of 56 and 700. The method of finding the greatest common measure is precisely the same both in the science of arithmetic and in that of concrete magnitudes. The proof may be briefly stated as follows: let A and B be two magnitudes, of which B is the less. Let A contain B m times, with a remainder R, or $\mathrm{A} = m\,\mathrm{B} + \mathrm{R}$. Then it is easy to show that every magnitude which measures (or is contained exactly a number of times in) A and B both, measures m B and A — m B or R; and also that every magnitude which measures B and R measures m B and m B + R or A. That is, all measures common to dividend and divisor are common to divisor and remainder, and all measures common to divisor and remainder are common to dividend and divisor. Therefore, the greatest of the common measures of either pair is that of the other. Now, carry on the division as follows until there is no remainder, which suppose to happen at the fourth step :—

$$\begin{array}{rlllll}
\text{Let } \mathrm{A} = & m\,\mathrm{B} + \mathrm{R} & \qquad \mathrm{R} & \text{is less than} & \mathrm{B} \\
\mathrm{B} = & n\,\mathrm{R} + \mathrm{R}' & \qquad \mathrm{R}' & ,, & \mathrm{R} \\
\mathrm{R} = & p\,\mathrm{R}' + \mathrm{R}'' & \qquad \mathrm{R}'' & ,, & \mathrm{R}' \\
\mathrm{R}' = & q\,\mathrm{R}'' & & &
\end{array}$$

Then R″ measuring itself, and also R′ or q R″, must be the greatest measure common to both, for nothing greater than itself can measure R″. But the greatest common measure of R″ and R′ has been shown to be that of R′ and R, which has been shown to be that of R and B, which has been shown to be that of B and A.

In the case of two numbers or fractions, a common measure must be found; for two whole numbers it must be a whole number, 1 at least, if not higher; for two fractions it must be a fraction. But in concrete magnitudes the process may continue without end, which indicates that the magnitudes are INCOMMENSURABLES, (which see for proof.) Hence the necessity, in all correct reasoning, of treating concrete magnitudes in the manner laid down in the fifth book of Euclid.

In Algebra the corresponding process does not ascertain the greatest common measure, which depends upon the specific values of the letters; but only the highest common factor, or that which has the highest dimensions. This part of algebra is frequently rendered singularly obscure by the application of the arithmetical word. Thus, though the highest algebraical factor of $a^2 - x^2$ and $a^3 - x^3$ is $a - x$; this last is not the greatest common measure in all cases, as the reader may try by supposing a and x to be 8 and 6.

COMMON PLEAS, COURT OF, one of the superior courts of record, having original jurisdiction over England and Wales in all common pleas or civil actions commenced by subject against subject. It is at present composed of five judges, one of them being chief justice and the other four *puisne* justices.

During the existence of the Aula or Curia Regis, established by the Conqueror in the hall of his usual residence, the palace at Westminster, that tribunal exercised supreme jurisdiction over all temporal causes, which were adjudicated upon by the principal officers of the royal household, often assisted by persons learned in the law, called the king's justiciars. In this state of things, the poorer class of suitors in the common pleas, between man and man, laboured under the heavy inconvenience of either attending the frequent and distant progresses of the court, or of losing their remedies altogether. This evil, as well as the jealousy entertained by the crown of the ascendancy of the chief justiciar, who presided over the whole Aula Regis, occasioned the article in Magna Charta, that common pleas should not follow the king's court, but be held in some certain place. This court of Common Pleas thereupon became gradually detached from the Aula Regis, and assumed its present separate form. It has ever since continued its sittings, without removal from the palace of Westminster or its immediate vicinity, except on a few occasions, in time of plague or contagious disease.

This court has by its constitution, an exclusive jurisdiction in all those actions, which, as they concern the right of freehold or realty, are called real, and on this account it is styled by Coke the "lock and key of the common law." The great mass of real actions have been abolished, and of the only three remaining—dower, right of dower, and quare impedit—this court has still exclusive jurisdiction. The Court of Common Pleas had originally also an exclusive jurisdiction in suits between subject and subject; but in these personal actions the Queen's Bench and Exchequer of Pleas have long exercised concurrent authority.

Before 1830, the appeal from the judgments of this court was by writ of error to the justices of the King's Bench; a vestige of superiority resulting to the latter as constituting the remnant of that Aula Regis from which this court as well as those of Chancery and Exchequer have been gradually carved out. But now by statute 11 Geo. IV. & 1 Will. IV., c. 70, the judgments of this court can only be reviewed by the judges of the other two superior courts of law, forming a court of error in the Exchequer Chamber; the further appeal thence is to the House of Lords.

Besides its ordinary jurisdiction, this court exercises a summary exclusive and final jurisdiction over railway and canal companies, under the statute 17 & 18 Vict. c. 31, and is also a court of appeal from the decision of the revising barristers. [ELECTION.]

The only persons admitted to audience as advocates in the Court of Common Pleas during its sittings in term were, till 1834, serjeants-at-law. [SERJEANT-AT-LAW.] By a royal warrant in April of that year, the right of audience was directed to cease to be exercised exclusively by the serjeants-at-law; and other counsel were to have an equal right with them so to practise there. Doubts having subsequently arisen as to the authority of the crown to abolish the privilege of the serjeants, the act 9 & 10 Vict. c. 57, was obtained to effect that object. (Blackst. 'Comm.,' Mr. Kerr's ed. vol. iii. pp. 29, 44.)

COMMON RECOVERY. [RECOVERY.]

COMMON, RIGHT OF, in law, is the right of taking a *profit* in the land of another in *common* with him, whence the name arises. Such a right enjoyed in exclusion of the owner of the land seems not to be properly common, though belonging to several persons together.

The profits which may be the subjects of common are the natural produce of land (or water, which is included in the legal signification of land); such as grass and herbage, turf, wood, and fish. The commons relating to these subjects are accordingly called common of pasture, turbary, estovers, and piscary. Other things which cannot be called products of land, but rather part of the land itself, as stones and minerals, may also be the subjects of common right. Rights of way and other accommodations in the land of another, though enjoyed in common, do not bear that name, but are called *easements*.

Of all commons, that of pasture is the most frequent. It is the right of taking grass and herbage by the mouths of grazing animals. It differs from that general property, which may exist in the *vesture* or vegetable produce of the land, without any property in the land itself, and which is a corporeal hereditament; whereas all commons are incorporeal, "as appears," says Blackstone, "from their very definition," an incorporeal hereditament being "a right issuing out of a thing corporate, or concerning or annexed to the same." (2 Bl. 'Com.' ch. 3.) The same remark applies to other commons, the subjects of which—as for instance woods and mines—may belong as corporeal hereditaments to one, while the land generally belongs to another.

Common of turbary is the right of taking turf for fuel; and common of estovers is the right of taking *wood* for fuel, and for the repairs of houses, fences, and implements of husbandry. These supplies of wood are called fire bote, house bote (which includes the former), plough bote, and hedge or hay bote. These estovers or botes may also be taken by every tenant for life or years from the land which he himself occupies, but they are not then the subjects of *common* rights.

Common of piscary is the right of *fishery* in rivers not navigable; the right of fishing in the sea and in navigable rivers being common to all the subjects of the realm.

The extent of rights of common depends very much upon the *title* to them. There are four titles on which such rights may be founded; common right (which seems to be nearly the same thing as the common law), prescription, custom, and grant.

The title by common right arose with the creation of manors, when land was granted out in fee to be *held* of the grantor as *lord*. As such grants were forbidden by the statute '*quia emptores*' (18 Edw. I., c. 1), it follows that all commons appendant now existing must have been created before the date of that statute. The law allowed to every such grantee, of course, and of common right, common of pasture, turbary, estovers, and piscary in the *waste* of the lord, or that part of his lands which was neither taken by him into his *demesne* or actual occupation, nor granted out by him to others. These implied rights of common however were allowed no farther than necessity seemed to require, and rights of common thus originating are still confined nearly within their ancient limits. Springing from grants of land, they were considered as inseparably *appendant* to the land, so that they could not be severed from it without extinguishment. The common of pasture was confined to the purpose of maintaining, from seed time to harvest, the cattle of the commoner which were used by him in cultivating his land, and which that land would maintain through the winter, or which were, as the law styled it, *levant* and *couchant* upon it. Horses, oxen, kine, and sheep, used either for tilling or manuring land, were the *commonable* cattle. The land to which the common was appendant must have been originally arable, though the subsequent change of arable into meadow, &c., does not extinguish the right. Common of turbary appendant was confined to the purpose of supplying fuel for the domestic use of the tenant; and so strictly must this right be still confined within its ancient limits, that it must be appendant to an ancient messuage, and no more turves can be taken under it than will be spent in the house. Common of estovers appendant gives, as it gave originally, only the right of taking wood for the repair of ancient fences and houses. Common of piscary appendant was only for supplying the tenant's own table with fish, and it must be still limited to this purpose.

Commons claimed by prescription (which supposes a grant) may be as various as grants may be. A right of common thus founded may be either annexed to land (when it is said to be appurtenant), or altogether independent of any property in land, when it is said to be *in gross*. If common of pasture, it may be for any kind of animals, whether commonable or not, as swine and geese. The number of animals may be fixed, or absolutely unlimited, and they need not be the commoner's own.

Common appurtenant may be severed from the land to which it was originally annexed, and then it becomes common in gross.

The title to common by custom is peculiar to copyholders, and may also give the commoner various modifications of right.

Right of common of pasture may also be claimed because of *vicinage*, or neighbourhood. This is where two wastes belonging to different lords of manors adjoin each other, without being separated by a fence. The cattle lawfully put upon the one common may then stray, or rather are excused for straying, into the other.

The rights of the owner of the soil over which a right of common exists, are all such rights as flow from ownership, and are not inconsistent with the commoner's rights.

Rights of common are conveyed, like all other incorporeal hereditaments, by deed of grant. When they are annexed to land, they will pass with the land by any assurance adapted to transfer the latter.

Rights of common are liable to be extinguished in several ways, and often contrary to the intentions of parties. It is a rule, that if the owner of common appurtenant purchases *any part* of the land over which the right extends, the right of common is *altogether* extinguished; it is the same if he release his right over any part of the land. This unreasonable rule however does not extend to common *appendant*, though that will be extinguished if the commoner becomes the owner of *all* the land in which he has common, and partial extinguishment of the common will follow from acquisition of part of the land. The enfranchisement of a copyhold to which a right of common is annexed extinguishes the right.

The most common mode of extinguishing rights of common in modern times is by inclosure under act of parliament, and these operations have been systematised by the general inclosure acts, under which commissioners have been appointed for the purpose of superintending inclosures, and the process rendered much less difficult and expensive than it formerly was. (See INCLOSURE; also generally on this subject Woolrych, on 'Rights of Common;' Comyn's 'Digest,' tit., Common; and Blackstone's 'Commentaries,' vol. ii. p. 34, Mr. Kerr's edit.)

COMMON, TENANCY IN, is one of the modes in which property may be held by several persons together. It comes the nearest to separate ownership, from which it differs in little else than that the shares held in common are not actually divided or marked out. As to alienation, transmission by descent, and other incidents of property, the law of undivided and of divided shares is the same. From the blending, however, of the shares, there necessarily arises some peculiarity in the mode of their enjoyment. When the profits of the thing held in common are partible (as corn growing in a field), they are generally actually divided among the tenants, and then the property of each most closely resembles separate property. It frequently happens, however, that this cannot be done; in which case the thing held in common must either be used alternately by the tenants (as a horse), or they must join in using it, as tenants in common of an advowson are required by law to concur in presenting to the church.

The shares of tenants in common may be either equal or unequal, and the quantity of their interests may be either equal or unequal. All may be tenants in fee, tenants for a term, &c., or one may be tenant in fee, and another tenant for a term, &c. It is necessary, however, that the possession of all be contemporaneous; successive interests are not a tenancy in common.

A tenancy in common may be created in several ways. If a joint-tenant, or coparcener, aliens his share to a stranger, the latter is a tenant in common with the remaining joint tenant or coparcener. If the sole owner of property aliens an undivided part of it, and retains the rest, the grantor and grantee are tenants in common. As to the words which, in a transfer of property to two or more persons, create a tenancy in common, or a joint-tenancy, many nice distinctions exist in the law. At common law, a conveyance of land to two simply, and without other words, made them joint-tenants, and not tenants in common; except in a few particular cases. (Litt., 283, 284.) This rule of law was founded on the feudal policy, which favoured the mode of holding property in joint-tenancy rather than in tenancy in common, because the former afforded room for the re-union of the property by survivorship (which is the characteristic incident of joint-tenancy) in a single individual, who might more effectually perform the duties belonging to the feudal tenure than several persons among whom the same burden was divided; and it is probable therefore that in the times of feudalism the intentions of grantors were fulfilled by implying joint-tenancy rather than tenancy in common. For a long time past however the courts have endeavoured, whenever they could, to raise by construction tenancies in common rather than joint-tenancies. But a tenancy in common might always be created by express words, and no technical expressions being necessary for the purpose, the courts have been enabled to lay hold of any words in a deed or will which appeared to them sufficiently expressive of a tenancy in common, in order to establish one. The misfortune however is that they have assumed greater latitude in this respect in the construction of wills and uses and trusts, than in the construction of common-law conveyances; so that the same words, as for instance the words "equally to be divided," often have different effects in different instruments.

The Courts of Equity have decided that in certain cases a simple conveyance to two or more makes them in equity tenants in common, and not joint-tenants, unless there is an express declaration to the contrary. This is the rule where a mortgage is made to two or more, and when an estate purchased by two or more is conveyed to them in unequal shares. This doctrine is sometimes in practice found very inconvenient.

A tenancy in common ceases as a matter of course, when the ownership of the several shares exists in a single individual; it can also be destroyed by partition made by the tenants. Any one of the tenants may compel the others, by suit in equity, to make partition of lands or houses held in common, except when the subject is in its nature not partible, as in the case of a living animal for instance.

Notwithstanding its many inconveniences, tenancy in common often occurs, being frequently created by wills and settlements in which property is given by suitable words to classes of persons together, as to children, or to a number of individuals by name. (See Blackst. 'Comm.' vol. 2, p. 186, Mr. Kerr's ed.)

COMMONS are wastes and pastures which have never been exclusively appropriated by any individual, but used in common by the inhabitants of a parish or district. Where extensive common rights exist, the mode of cultivating the inclosed land is greatly affected by it. All the cattle being maintained on the commons for a great part of the year, less land is laid down to grass, and only so much is kept in meadow as will produce hay to feed the cattle in winter weather, and when the commons will not sustain them. The consequence is, that the arable land is not well cultivated, little manure is made in the yards, and the rent is paid by the stock which runs on the commons, and which increases and grows without any expense to the owner. But it is a wasteful disposition of the land. Common pastures are never improved; no one will drain or clear them of weeds, still less manure them. The stock kept upon them is not by any means so numerous as could be kept on the same surface divided and improved. Hence most of the commons and common fields in Great Britain have been divided and inclosed within the last fifty years. Wherever an inclosure has taken place the public has gained, even when the individuals immediately connected with the land may have suffered some loss, by not receiving an equivalent for the profit they had from the cattle which they contrived to keep on the commons.

The soil of commons within a manor belongs to the lord; if there is no manor, it belongs to the king. The herbage belongs in general to the tenants and other inhabitants of the manor or districts, according to fixed rules. Where commons are very extensive there is sometimes no restriction on the number of cattle which may be turned out on them. This is called *common without stint*.

The usual proportion given to the lord for his right in the soil on an inclosure is one-sixteenth. The remainder is divided among those who have a right of common in proportion to the land they possess, and on which their right depends.

Common fields differ from commons, in that they are divided for the purpose of cultivation; but as soon as the crop is off the ground, the cattle of all the proprietors, or of all the parishioners, as the custom may be, have a right of pasture over the whole in common. This system is incompatible with an improved husbandry, and common fields have been very generally divided and inclosed by particular acts of parliament. The General Inclosure Acts of late years have greatly facilitated these inclosures, and the number of common fields is probably not now very great.

COMMONS, HOUSE OF. The object of this article is to present a distinct though compendious view of the history and actual state of the House of Commons as a part of the Imperial Parliament of Great Britain and Ireland. In considering the history of the English borough system, it must be borne in mind that the municipal organisation of the Anglo-Saxons, though not confined to the towns, was best remembered in them; and when after the Norman invasion, the towns became subject to a royal bailiff, who levied taxes almost at his pleasure, of which only a small portion reached the royal exchequer, the oppression was severely felt, and strong efforts were made to relieve themselves from it. Very early the towns, by offering better terms than were obtained from the bailiff, obtained the power of electing their own mayor, or port-reeve. For this purpose charters were granted, and self-governing municipalities were re-formed. It was natural, when the chief object of the assembling of a parliament was taxation, to apply to these municipalities. They represented considerable bodies of people already united for a somewhat similar purpose, and they already raised tolls and imposed several taxes. The original basis of the representation, however, in the time of Edward I., was very different from what we must suppose it would have been made, had the crown and its advisers at that period contemplated in this arrangement any such thing as the composition of a legislative assembly. The very large proportion of the whole number of its members that were sent from the towns, at a period when the population and general importance of the towns, as compared with those of the counties at large, were vastly less than they are now, was manifestly a circumstance repugnant to all the political notions and tendencies of the government of that day. Under Edward I. the town representatives bore so large a proportion to those of the shires as 246 to 74; and under Edward III. as 282 to 74. The reason why, on the first settling of the representative system into regularity and permanency, each constituency was uniformly summoned to elect *two* members, without regard to its known or presumed proportion of wealth or populousness, seems to have been very simple and very natural. So long as the parliamentary voice of the commons was confined to matters of taxation merely, the only thing that appears to have been seriously regarded in fixing the number of delegates was the securing such a delegation from each constituency as at the smallest inconvenience and expense to the latter should have full power to treat of the pecuniary business in question; and *two*, being the smallest number compatible with the important conditions of mutual consultation and joint testimony, was fixed upon as the number that imposed the smallest burden on the constituents, and was also most convenient for avoiding a too crowded assemblage of representatives. And thus it seems to have been that the periodical and frequent shire and borough courts presenting the most natural and convenient modes and occasions of appointing the parliamentary deputies of the several communities, two representatives, and two only, were summoned indifferently from the shire as from the borough, and from the largest shire or borough as from the smallest.

When the power and authority of the commons in parliament had become so firmly consolidated under the first three Edwards as to exercise an effective control over all the great measures of government, the composition of the representative body was an object of constant attention and solicitude to the crown. As the number and names of the counties entitled to send members admitted neither of doubt nor of dispute, the right of the *boroughs* became the first object of attack from that quarter. The parliament having in 1297 (25 Edward I.) procured the passing of the act called "Statutum de tallagio non concedendo," which enacts that "no tallage or aid shall be taken or levied by us or our heirs in our realm without the good will and assent of the archbishops, bishops, earls, barons, knights, burgesses, and other freemen of the land," it became important to influence the borough as the most numerous body.

The great instruments of the crown in influencing the *composition* of the popular representation, especially of the borough portion of it, were, the *sheriffs* of the several counties returning members, of which, in the time of Edward I., there were thirty-seven; Durham and Cheshire having then palatinate parliaments of their own, and Monmouthshire being part of Wales, which was not yet legislatively incorporated with England, nor even effectively subjected to the English crown. It was as the king's *bailiff*, that is, as local superintendent and collector of the crown revenues, that the precepts for election of knights, citizens, and burgesses were addressed to this officer; he was to make returns for every city and borough in his *bailiwick*—another mark of the original purpose for which the popular representatives were convened, that of taxation only. So long as this continued to be the sole object of their convocation, and so long as the delegated burgesses themselves had little voice in fixing the rate of impost to be levied on their constituents, it is not surprising that the smaller boroughs in particular should often have petitioned to be excused from the sending of delegates on these occasions, which added to their share of the public burden, the expense, to them considerable, of the wages which by royal writ they were to pay their representatives during their absence on this parliamentary service, and which were fixed at two shillings each per day, being one half the amount appointed to be paid by the county freeholders on the like occasion to a knight of the shire. As the king's writ addressed to the sheriff specified no particular city or borough, but required him in general terms "to cause to be elected two citizens for each city, and two burgesses for each borough in your bailiwick," a sort of discretionary power seems to have rested with the sheriff of determining what towns were qualified to send representatives. Thus we find the returns made by these officers concluding sometimes with the words "there are no more cities or boroughs in my bailiwick," though there were in fact more boroughs; and sometimes ending with "there are not any other cities or boroughs within the county from which any citizens or burgesses can or are accustomed to be sent to the said parliament, by reason of their decay or poverty." Immaterial as this circumstance in the original framing of the parliamentary writs might appear at the time, its results have been momentous. It must have been remote indeed from the contemplation both of Simon de Montfort and of Edward I., that in convoking so large a number of delegates from towns, in order to tax them with greater facility and uniformity, they were laying the foundation of a separate house of legislature, wherein the representatives of that part of the population most alien to the feudal organisation should vastly preponderate. They evidently looked not so far, nor suspected any latent danger in the generality of the terms in which these precepts were couched. But when the commons came to assert and establish their claim to a full and free *legislative* voice, and it consequently became of the highest importance to the crown to secure to itself any and every means of influencing the composition of that assembly, there was one expedient to which it was too late to resort, that of singling out boroughs for representation, or omitting them at pleasure. The contrary precedent was firmly established—that, through the sheriff, every city and borough was to be summoned; the original terms of the writ were grown into an inviolable constitutional maxim; and in the fifth of Richard II., the Commons were already sufficiently powerful to procure statutory enactments imposing a fine on any sheriff who should not *literally* obey the writ, and subjecting *citizens and burgesses*, as well as others having parliamentary summons, to be "amerced or otherwise punished" for non-attendance. And although notorious inability, from devastation by war or other calamity, to pay the parliamentary wages of representatives, continued long after to be admitted as a valid plea of exemption from electing in the case of individual boroughs, the great principle of the *right* of every municipal town to be summoned, and its *duty* to return members, if capable, was constantly and firmly maintained.

In like manner, statutes were passed in the three following reigns to restrain the corrupt and irregular proceedings of the sheriffs both in county and in borough elections.

Hitherto, however, the parliamentary determinations of the commons, as regarded the constitution of their own house, had constantly tended to maintain the political rights of their constituents against invasion on the part of the crown. But that firm and lasting establishment of their own power as a distinct legislative body, which may be dated from the great revolution that first brought the house of Lancaster to the throne, seems, by that very additional security which it gave them against royal encroachment, to have tended to embolden the house, not, as formerly, to maintain the elective franchise to the utmost with the same zeal with which they upheld their own interest and independence as a legislative chamber, but to commence a sort of reaction against the constituent bodies by narrowing the basis of the suffrage itself. The earliest of these disfranchising enactments, and one of the most remarkable, is that of the 8th Henry VI., restricting the county franchise, formerly possessed by all freeholders, to such only whose freeholds were worth clear forty shillings a year, a sum at least equal to twenty pounds of the present day. The next remarkable instance, though very different in its nature, of legislative enactments respecting the constitution of the commons' house, appears in the parliamentary incorporation of Wales and Cheshire in the reign of Henry VIII., which brought an accession of sixteen county and fifteen borough members.

The *borough* representation in general was still the great object of attention to the Crown in undermining the independence of the House of Commons. The development of that part of its policy was diligently pursued under the later reigns of the Tudors, and carried to the utmost limit by the Stuarts; 1st, by creating or reviving parliamentary boroughs, and at the same time remoulding their municipal constitutions according to the views of the court; 2nd, by proceeding to assimilate the municipal constitutions of the old parliamentary boroughs to those of this newly-created class. The last addition to the English representation previous to the changes made by the Reform Act, was, under Charles II., the enfranchisement by statute of the county and city of Durham, and the creation by charter of the parliamentary borough of Newark. Nor must we forget to mention that James I., by virtue of his royal prerogative, had conferred the right of electing two members upon each of the two universities of Oxford and Cambridge, quite independent of the city and borough representation of those places already existing: thus introducing an anomaly, as well as novelty, into the representative system, a sort of forced alliance between learning and politics, emanating from the peculiar mental constitution and training of that prince.

Those who conducted the revolution of 1688 made much more effectual provision against the return of Roman Catholic ascendancy than they did for the purification of the representative system. The Bill of Rights does, indeed, express, "that the election of members of parliament ought to be free;" but this vague declaration seems to have amounted to nothing more than an indication of the prevailing public opinion on the subject. We find another strong proof that the public attention had now begun to be directed, not merely, as in former times, to upholding the authority of the Commons' House as constituted in parliament, but to the nature of the relations, on the one hand between the house and the constituent body of the nation, on the other between the several members and their individual constituencies, in the enacting of the statute commonly called "the Triennial Act," which deprived the crown of the power of continuing the same House of Commons for a longer period than three years. The Triennial Act of 6 & 7 William and Mary, c. 2, was an enactment wholly on the side of electoral freedom. The discretionary power previously exercised by the crown, not only of dissolving, but of continuing at pleasure, was highly favourable to any such view, on the part of the crown, as that of forming a tacit compact with a corrupt or servile majority of the Commons' House, and was therefore, as had been lately seen under Charles II., exceedingly convenient both to king and commons, when the latter happened to be sufficiently pliant. So strongly, however, was the popular opinion on this point expressed at the period in question, that it compelled the commons to persist in the measure in spite of King William's refusal of assent to the bill after its first passing the two houses, so that on the second occasion his assent was reluctantly yielded. The same activity of the public opinion of that day respecting the composition of the commons, produced the several Acts of that reign which disqualify various classes of placemen for seats in the house.

In this place we must notice the legislative union with Scotland, effected in 1707 by statute 6 Anne, c. 8, only to mention that it brought an accession to the English (which thereby became the British) House of Commons, of thirty members for counties, and exactly half that number for cities and boroughs; exhibiting between the numerical amount of the county and that of the borough representation a proportion quite the reverse, not only of that which existed in England, but of that which had previously appeared in the Scottish parliamentary representation.

The same reign presents us with an enactment of the British House of Commons respecting its own future constitution, totally different in character from those of William III.'s time just referred to. This is the very important Act (9 Anne, c. 5), which established the qualification of landed property for English members, whether for counties or boroughs. In the reign of Henry VI., which gave birth to the enactment disfranchising the smaller county freeholders, was passed an Act, in the same spirit, restricting the choice of those freeholders who still retained the franchise. The very terms of this statute imply, that in the case of the counties, as in that of the boroughs, there was originally no legal distinction between the qualification of the electors and that of the elected, but that the former were simply called upon to return two of their own number according to their own best discretion. The circumstance, too, of the daily expenses uniformly paid under legal obligation by the constituents to each representative while absent on parliamentary duty, may in this place be properly mentioned as a striking evidence of the fact, that the qualification of considerable property, how much soever it might be regarded in the judgment of the constituents, was, originally, not at all contemplated by the law. The statute in question (23 Henry 6, c. 14) declares, that thenceforward the county representatives shall be "notable knights of the same counties, or shall be able to be knights," that is, shall have freehold to the amount of 40*l.* per annum, and that no man shall be eligible "that stands in the degree of a yeoman or under." On this legal footing the county representation remained until the ninth year of Queen Anne, when not only was the landed property qualification reenacted for the counties on a scale nearly proportioned to the decrease in the nominal value of money, but an unprecedented step was taken, by including in the very same clause of the same Act a provision, that while every knight of the shire should possess a freehold or copyhold estate of clear 600*l.* per annum, so also every citizen, burgess, or baron of the Cinque Ports should have the like landed qualification to the amount of 300*l.* per annum. The statute of the 1st Geo. I., commonly called the Septennial Act, which extended the legal duration of parliaments from three years to seven, how cogent soever might be the political motives of the chief promoters of the measure, is another memorable instance of the lengths to which the House of Commons could now venture in dealing in a wholesale manner with the elective rights of its constituents.

One of the most important operations of the British House of Commons during the period above mentioned, was the enacting of the statute, passed in 1800, and taking effect from January 1st, 1801, by which it incorporated the parliamentary representation of Ireland with that of Great Britain. For the previous history of the Anglo-Irish representation, and the degree of alteration made in it by the Act of Union, we refer to Parliament of Ireland. Sixty-four members for counties, thirty-five for cities and boroughs, and one for Dublin university, were thus added to the number of the British House of Commons. In this instance, as in that of the Scottish union, the ancient proportion between the city and borough representation was reversed, and an additional weight consequently thrown into the scale of the county representation of the United Kingdom at large.

It is needless to encumber our pages with a list of the places now returning members of parliament, since these may be seen, with the names of the members, published annually in a variety of shapes; and it is the less necessary, as a bill for reforming the constitution of the House of Commons is promised to be introduced by ministers in 1860, which will, if carried, in all probability considerably modify the existing arrangements.

Elective Franchise. Counties. England and Wales.—Until the Reform Act, the parliamentary franchise in counties had remained without extension or alteration, as limited full three centuries before by the statutes of the 8th and 10th of Henry VI., the former of which confined the right to such "as had freehold land or tenement to the value of 40*s.* by the year at least above all charges;" the latter to "people dwelling and resident within the county, &c., whereof every man shall have freehold to the value of 40*s.* by the year." In order to render a man a freeholder, and complete his qualification for voting, it was necessary, not only that he should have a freehold interest in his lands and tenements, but that he should hold them by freehold tenure: consequently copyholders, holding by what is technically termed *base* tenure, as well as *termors*, having only a chattel interest in their estates, were excluded from voting. Doubts having been raised as to the right of copyholders, it was expressly enacted by the 31 George II. c. 14, that no person holding by copy of court-roll should be thereby entitled to vote. The Reform Act extends the franchise by admitting not only copyholders, but leaseholders, and even occupiers, under certain limitations; and abridges it in some cases of freeholds not of inheritance, as also in all cases of land situate in a city or borough, and which being occupied by the proprietor would give him a parliamentary vote for that city or borough. In establishing the right to the county franchise, questions of tenure and interest have become of comparatively little importance, except as they are connected with value; for now what is commonly, though improperly, called a tenant at will (that is, from year to year) occupying land of the annual rent of 50*l.* has a right to vote for a county, without reference to the tenure by which the lessor holds the land, or the interest that he may have in it. By 18 Geo. II., c. 18, s. 5, it was enacted, that no person should vote for a county unless he had been for twelve calendar months in actual possession of the rents and profits to his own use, except in particular cases. But by the statute of 1832, by s. 26 it is enacted, that no person shall be registered as a freeholder or copyholder, unless he was in actual possession of the rents and profits for six months previous to the last day of July of the year wherein he claims to be registered. Leaseholders and their assignees, and yearly tenants, must have occupied for twelve months before the same period, except in the cases excepted by the abovementioned statute of George II. Value, therefore, has now become the criterion upon which, in many cases, the right of voting wholly depends; and in all cases it is a most material subject of inquiry, in order to determine in what character, whether as freeholder, copyholder, leaseholder, or occupier, an elector should make his claim to be registered.

1. If lands or tenements are held at a yearly rent of 50*l.*, bare occupation, as tenant from year to year, is sufficient to qualify; no further interest in the lands, &c., being necessary, and it being immaterial by what tenure they are held. 2. So also is the occupation of lands, &c., of 50*l.* yearly value, as sub-lessee or assignee of any under-lease created originally for a term of not less than 20 years, how small a portion soever of the original term may remain unexpired. 3. The original lessee of a term created originally for 20 years, of lands of 50*l.* yearly value, or the assignee of such term, is entitled to vote in like manner, whether or not he is the occupier of such lands. 4. The occupier of lands of 10*l.* yearly value, as sub-lessee or assignee of any under-lease of a term of not less than 60 years. 5. So likewise the original lessee, or the assignee of such a term of the lands of 10*l.* yearly value, is entitled, whether occupying or not; nor is the nature of the tenure material in any of the above cases; but twelve months' possession previous to the last day of July is required in all. 6. The being seised of an estate—whether of inheritance or for a life or lives—whether freehold, copyhold, or of any other tenure, to the like yearly value of 10*l.*, entitles.

Freehold lands or tenements of 40*s.* yearly value are still sufficient to give a vote in the four following cases:—

1. If it be an estate of inheritance. 2. If not an estate of inheritance, but only an estate for life or lives, if the elector was seised previously to the 7th of June, 1832 (the day on which the act received the royal assent), and continues so seised at the time of registration and of voting. 3. If acquired subsequently to that day, if the elector be in actual and *bonâ fide* occupation at the time of registration and of voting. 4. Or if acquired subsequently to that day, if it came to the elector by marriage, marriage settlement, devise, or promotion to any benefice or any office.

Of freehold or copyhold estates six months' possession, and of leasehold estates twelve months', is required, previously to the last day of July, in the year of registration, except they come by descent, succession, marriage, marriage settlement, devise, or promotion, &c.

Now, also, it has become material to consider how the lands or tenements are locally situated: for if they are freehold within a city or borough, and in the freeholder's own occupation, so as to confer a right to vote for such city or borough,—or if copyhold or leasehold, and occupied by him or any one else so as to give the right of voting for such city or borough to him or any other person,—they cease to qualify for a county vote.

However, by the 16th section of the act, an express reservation is made of all *existing* rights of suffrage possessed by county freeholders, provided they are duly registered according to the provisions of the act itself.

Scotland.—Under George II. enactments were made which rendered the proving of the old forty-shilling votes yet more difficult, so that many more of them disappeared, and at the close of the last century very few remained. Although the Scottish act of 1681 enacted that the right of voting should be in persons publicly infeoffed in property or superiority of lands of 40*s.* old extent, or of 400*l.* Scots valued rent, thus making a distinction, it should seem, between property and superiority, yet it was constantly interpreted to mean that superiors, that is, tenants-in-chief, or persons holding immediately of the crown, were *alone* entitled to vote. Thus proprietors of estates, of whatever value, holding from a subject, were excluded from the franchise. It is computed that in several counties nearly one-half the lands were held in this manner, and in the whole kingdom one-fifth of the lands were so held. The class of landholders thus excluded comprised not only the middling and smaller gentry, and the industrious yeomen and farmers who had inherited or acquired some portion of landed property, but also some men of estates worth from 500*l.* to 2000*l.* per annum; while many persons, who had not the smallest actual interest in the land, possessed and exercised the elective franchise. When a person of great landed property wished to multiply the votes at his command, his course was, to surrender his charter to the crown, to appoint a number of his confidential friends, to whom the crown parcelled out his estates in lots of 400*l.* Scots valued rent, and then to take charters from those friends for the real property, thus leaving them apparently the immediate tenants of the crown, and consequently all entitled to vote. This operation being open as well to peers as to great commoners, they availed themselves of it accordingly, thus depreciating or extinguishing the franchises of the smaller proprietors. This legal fraud began in the last century, and was chiefly practised subsequently to the accession of George III. Among the various modes by which it was performed, the most common were by life-rent charters, by charters on *wadset* or mortgage, and by charters in fee. The parliamentary representation of the Scottish counties therefore had, according to the expression of a learned lord, "completely slid from its basis." The total number of county voters, as compared with the number of persons directly interested in the property of the soil, was extremely small, and of these the number of real votes scarcely exceeded that of the fictitious ones.

The basis of county suffrage was, by the Reform Act for Scotland, to be assimilated, as closely as the difference between the modes of possessing and occupying lands, &c., in the two countries would permit, to the system established for England and Wales. While the old class of rights to the suffrage was preserved to the individuals in actual possession of them before March 1st, 1831, provision was made against their perpetuation; while the body of electors newly admitted consisted of owners to the value of 10*l.* a year,—of leaseholders for 57 years or for life, whose clear yearly interest was not less than 10*l.*—of leaseholders for 19 years where such yearly interest was worth not less than 50*l.*,—of yearly tenants whose rent was not less than 50*l.* per annum,—and of all tenants whatsoever who had paid for their interest in their holding an amount not less than 300*l.* The same difference was made as in the English act, between the freeholder and the mere occupier, as to the *six* months' proprietorship required in the former case and the *twelve* months' occupancy in the latter; and the like exceptions from this condition as to the length of possession in favour of cases wherein either ownership or lease came to a person by inheritance, marriage, marriage settlement, "*mortis causâ* disposition," or appointment to any place or office.

Ireland. The act of union made no alteration in the parliamentary suffrage of the Irish counties. The qualification of a freeholder remained the same as before, a clear annual forty shilling interest for a life: and as it was customary in Ireland to grant leases on lives, freeholders were thus created whose votes, from their extreme poverty, and consequent inability to discharge their legal obligations to their landlord, were disposable by him as a matter of course. This practice of multiplying freeholds for election purposes merely was carried to an excessive and most mischievous extent, reducing the franchise almost to universal suffrage, among individuals who, by the very instrument by which they were professedly made free, were reduced to the most abject state of political bondage. Thus many of the counties, in choosing their representatives, lay under the absolute dictation of some great territorial proprietor; and there were few in which a coalition of two or three of the principal landowners would not determine the election according to their own wishes. Under these circumstances, the provision of the Roman Catholic Emancipation Act of 1829, which raised the freehold qualification in the counties of Ireland from 40*s.* to 10*l.*, can hardly be regarded as a virtual disfranchisement.

The whole civil organisation of Ireland having been introduced directly from England, and the system of tenures in particular being the same in both countries, the provisions of the Irish Reform Act which have reference to the territorial franchise are more strictly analogous to those of the act for England than those of the Scottish act could well be made, at least in appearance. The existing freehold rights being preserved here, as in the other two divisions of the empire, to their individual possessors, and the 10*l.* freehold franchise being already established by the above-mentioned provision of the act of 1829, the classes of the electors newly created were: 1. The 10*l.* copyholders. 2. Lessees or assignees having a clear yearly interest of 10*l.* in a leasehold created originally for 60 years or upwards, or of 20*l.* in a leasehold of not less than 14 years, whether in their actual occupancy or not. 3. Sub-lessees or assignees of any underlease in either of the two cases just mentioned, actually occupying. 4. The immediate lessees or assignees, and they only, having a 10*l.* yearly interest in a 20*l.* lease, and actually occupying. The like provision is made as in the English act, against any title to the county franchise being derived from any holding whatever that would entitle to vote for a city or borough.

Cities and Boroughs. England and Wales.—The want of any uniform basis of suffrage in the parliamentary boroughs, the endless diversity of the claims to its exercise derived from the various political as well as local influences that had operated upon them in the course of ages,—a diversity which the numerous, various, and often conflicting decisions of election committees of the House of Commons had additionally complicated and confused—was one of the most grievous defects of the old representative system. The generally prevailing custom, too, that the non-residence of borough voters entailed no disqualification, was one of the most serious evils comprised under this head. The Reform Act prepared the way for sweeping off all the claims to the franchise founded on the old and long-abused titles to borough freedom, by establishing a uniform qualification, resting chiefly on the basis of inhabitancy.

It provided, that in every city or borough which shall return members, every male person of full age and not subject to any legal incapacity, who shall occupy, within such city or borough, or within any place sharing in elections with it, as owner or tenant, any house, warehouse, counting-house, shop, or other building, either separately or jointly with any land, of the clear yearly value of not less than 10*l.*, shall, if duly registered, as directed in another part of the Act, be entitled to vote in the election of members for such city or borough; provided always, that no such person shall be so registered in any year, unless he shall have occupied such premises for twelve calendar months previous to the last day of July in that year; nor unless such person, where there shall be a rate for the relief of the poor, shall have been rated to all rates for the relief of the poor made during such his occupation; nor unless such person shall have paid, on or before the 20th of July in the same year, all the poors' rates and assessed taxes due from him previously to the 6th of April preceding; provided also, that no such person shall be so registered unless he shall have resided for six calendar months previous to the last day of July within the city or borough, or within the place sharing in the election, or within seven miles thereof. The premises in respect of the occupation of which any person shall be entitled to be registered as a voter, need not be always the same premises, but may be different premises occupied in immediate succession by such person during the twelve calendar months previous to the last day of July: such person having paid, on or before the 20th of July, all the poors' rates and assessed taxes due before the 6th of April preceding, in respect of all such premises so occupied by him in succession. Furthermore, when any premises in any such city or borough, or place sharing in the election, shall be jointly occupied by more persons than one, each of such joint occupiers shall be entitled to vote, in case the clear yearly value of such premises shall be of an amount which, when divided by the number of such occupiers, shall give a sum of not less than 10*l.* for each occupier. And in every city, borough, or place sharing in the election, it shall be lawful for any person occupying as above specified in any parish or township in which there shall be a rate for the relief of the poor, to claim to be rated; and upon such occupier so claiming, and actually paying or tendering the full amount of the rates, the overseers are to put the name of such occupier upon the rates; and in case such overseers shall neglect or refuse so to do, such occupier shall nevertheless be deemed to have been rated.

The formerly anomalous position of cities and towns which are counties of themselves, as regards the possession of the elective franchise, was rectified by the Act. Such counties of cities and towns are now included, for the purposes of county elections, in the several counties at large, or divisions of counties, in which they are locally situated—with this restriction only as regards freeholds for life; that no person shall be entitled to vote in the election of knights of the shire, or of members for any city or town a county of itself, in respect of any freehold whereof such person may be seised for his own life, or for the life of another, or for any lives, except such person shall be in the actual occupation, or except the same shall have come by marriage, marriage settlement, devise, or promotion to any benefice or to any office, or except the same shall be of the clear yearly value of not less than 10*l.* It was further provided that in every city or town being a county of itself, in the election for which freeholders or burgage tenants, either with or without any superadded qualification, had previously a right to vote, every such freeholder or burgage tenant should be entitled to vote, if duly registered: but no such person to be so registered in respect of any freehold or burgage tenement, unless he shall have been in actual possession thereof, or in receipt of the rents and profits for his own use, for twelve calendar months previous to the last day of July (except where the same shall have come to him, within such twelve months, by descent, succession, marriage, marriage settlement, devise, or promotion to any benefice or office), nor unless he shall have resided for six calendar months previous to the last day of July within such city or town, or within seven miles of it;—the limits of such city or town a county of itself, being, for the purposes of this enactment, those settled by the general parliamentary Boundary Act for England and Wales. Similar provision as to length of occupancy, &c., is made in the case of persons having a previous freehold qualification to vote for any of the boroughs of Aylesbury, Cricklade, East Retford, or New Shoreham.

Such are the provisions which constitute what is popularly called, by reference to their most prominent feature, "the ten-pound householder qualification."

But as in the settling of the places which were thenceforward to elect, and in apportioning the members, the new Act made a large compromise with the old system, so also it made no inconsiderable one, for a season at least, in sparing to a certain extent the rights to the parliamentary franchise grounded on the old titles to borough freedom. In all such cases, however, it imposed the very important condition of residence. It provides that every person who would have been entitled to vote in the election of members for any city or borough as a burgess or freeman, or in the city of London as a freeman and liveryman, shall be entitled to vote if duly registered; and that every other person having, previous to the Act, a right to vote in the election for any city or borough by virtue of any other qualification than those already mentioned, shall retain such right so long as he shall be qualified as an elector according to the usages and customs of such city or borough, or any law in force at the passing of the Act, and shall be entitled to vote if duly registered; but in both of the above cases it is enacted that no such person shall be so registered unless he shall, on the last day of July, be qualified in such manner as would entitle him then to vote if such day were the day of election; nor unless for six calendar months previous to that day he shall have resided within such city or borough, or within seven miles from the place where the poll shall heretofore have been taken, or, in the case of a contributory borough, within seven miles of such borough. As regards the second class of voters last mentioned, it is further enacted that every such person shall for ever cease to enjoy such right of voting if his name shall have been omitted for two successive years from the register of parliamentary voters for such city or borough, unless he shall have been so omitted in consequence of his having received parochial relief within twelve calendar months previous to the last day of July in any year, or of his absence on naval or military service.

The expedient to which, to serve party purposes during the agitation of the Reform measure, many of the governing bodies of corporations had resorted, of admitting unusually large numbers of freemen, occasioned the following limitations of the above reservation of the elective franchise of freemen to be introduced into the Act, namely: That no person who shall have been elected, made, or admitted a burgess or freeman since March 1st, 1831, otherwise than in respect of birth or servitude, or who shall hereafter be so, shall be entitled to vote; that no person shall be entitled as a burgess or freeman in respect of birth, unless his right be originally derived from or through some person who was a burgess or freeman, or was entitled to be admitted as such, before the said 1st of March, 1831, or from some person who since that time shall have become, or shall hereafter become, a burgess or freeman in respect of servitude; and that no person shall be entitled to vote for any city or borough (except it be a county of itself) in respect of any estate or interest in any burgage tenement or freehold which shall have been acquired by such person, since the same 1st of March, 1831, unless it shall have come to such person previously to the passing of this Act, by descent, succession, marriage, marriage-settlement, devise, or promotion to any benefice or office.

It also provided in general, that no person shall be entitled to be registered in any year as a voter for any city or borough who shall, within twelve calendar months previous to the last day of July in that year, have received parochial relief or other alms which, according to the previously existing law of parliament, disqualified from voting.

Scotland.—Owing to the previous absence of all popular suffrage in the Scottish boroughs, the revolution made in their parliamentary constituencies by the Reform Act of 1832 was effected simply, completely, and at once. The franchise was taken from the members of the town councils and their delegates, in whom as such it was before exclusively vested, and a 10*l.* qualification, by ownership or occupancy, substituted in its place, with the like conditions, as in the English Act, of twelve months' previous occupancy, payment of assessed taxes, registration, and non-receipt of parochial relief.

Ireland.—In the Irish cities and boroughs, the change immediately worked by the Parliamentary Reform Act was relatively greater than in England, owing chiefly to the fact that the municipal corporations of the former country existed in a state yet more thoroughly anomalous and corrupt than those of the latter. Here, again, the actually existing and the inchoate titles to the parliamentary suffrage being reserved, as in the English Act, on condition of residence within seven miles, and honorary freemen created since March 30, 1831, being excluded, the 10*l.* ownership or occupancy qualification was established as the new basis of suffrage, on condition of registration with *six* months' previous occupancy and payment of all rates due for more than one half-year. Reservation was also made, as in the English boroughs, of rights by freehold under 10*l.*, when accruing before the passing of the Act, by descent, marriage, &c. The clause of the Catholic Emancipation Act, which raised the freehold qualification in counties at large to 10*l.*, left it at the old amount of 40*s.* in the several counties of cities and towns; but the Reform Act raised it there to the same scale as in the counties at large (only reserving for life the existing 40*s.* rights), and at the same time gave the parliamentary franchise for such corporate counties to the same classes of leaseholders, and on the same conditions, whom it admitted in the counties at large.

Universities.—In the two English universities the parliamentary suffrage is independent of residence, property, or occupancy, being vested in the doctors and masters of arts of Cambridge and Oxford respectively, so long as they keep their names on the boards of their respective colleges. In the University of Dublin, in like manner, it is possessed by the fellows, scholars, and graduates of Trinity College, on the like condition.

The establishment of a general and uniform system of registration of voters, calculated to obviate much of the inconvenience of contested returns, is another very important feature of the Reform Acts; for the various and rather complicated details of which we must refer the reader to the Acts themselves.

Having thus given a view of the qualifications for exercising the parliamentary franchise as now established throughout the British Islands, it remains to notice the principal of those legal disqualifications which are of a personal nature, and operate independently of all proprietorship or occupancy.

Every woman, of whatever age, and however independently situated as to property and social relations, is as much excluded from voting as from being elected. As to age in male persons, the only exception is that which excludes all minors; that is, all who have not completed their twenty-first year. The exception which regards *aliens* is so natural and obvious that the bare mention of it may here suffice, as this is not the place in which to examine the various difficulties that in many cases have arisen, and still arise, in strictly defining who are aliens and who are not. By the ancient "law of parliament," which forms an integral portion of the common law, lunatics are very reasonably incapacitated, as also are paupers in city or borough elections. It was resolved by the House of Commons in 1699 (14th December), that "no peer of parliament" has a right to vote for members of that house. After the Union with Ireland, this resolution, which was usually repeated at the beginning of every session, was altered into the following form: "That no peer of this realm, except such peer of that part of the United Kingdom called Ireland as shall for the time being be actually elected, and shall not have declined to serve, for any county, city, or borough of Great Britain, hath any right to give his vote in the election of any member to serve in parliament." The vast increase, since the commencement of the last century, owing to the establishment of so many new branches of revenue, in the number of persons employed immediately by the crown as revenue-collectors, occasioned the enactment of several statutes of exclusion from the parliamentary franchise. Thus the 22nd George III. c. 41, excludes every class of officers concerned in the collection or management of the excise, customs, stamp duties, salt duties, window and house duties, or in any department of the business of the post-office. By 3 George IV. c. 56, s. 14, it was first enacted that no justice, receiver, surveyor, or constable, appointed by that Act at any one of the eight police-offices of the English metropolis, shall be capable of voting for Middlesex, Surrey, Westminster, or Southwark; and by 10 George IV. c. 44, which established the new system of police in certain districts of the metropolis (the operation of which has since been extended to meet the local extension of the police system), it was enacted that no justice, receiver, or person belonging to the police force appointed by virtue of that Act, shall be capable of voting for Middlesex, Surrey, Hertfordshire, Essex, or Kent, or for any city or borough within the metropolitan district. Persons legally convicted of perjury or subornation of perjury, or of taking or asking any bribe, are thereby for ever incapacitated from voting.

As regards religious grounds of disqualification in general, it should be observed, that as no oaths are now required to be taken, nor declarations to be made, as a preliminary either to registration or to voting, all such disabilities as might have arisen from refusal to take or make them are of course removed.

Qualifications of Candidates and Members.

Of the close relation so long subsisting between the grounds of the elective franchise and of eligibility to be elected, and which had sprung from their original identity, we find distinct traces in the similarity between the heads of disqualification in either case. Women, minors, aliens, and lunatics are, of course, excluded in the latter case as well as the former. It would be needless to remark, that peers of *parliament*—that is, actual members of the House of Lords—are ineligible to the House of Commons, except in order to point out this distinction: that any Irish peer, not being among the twenty-eight sitting in the House of Lords for the time being as representatives of the Irish peerage, and being, therefore, though a peer of the realm, not a peer of parliament, is eligible to represent any constituency in the United Kingdom, although such is not the case with Scotch peers who are not representative peers. No person concerned in the management of any duties or taxes created since 1692 (except commissioners of the Treasury), nor any officer of the excise, customs, stamps, &c., nor any person holding any office under the crown created since 1705, is eligible. In like manner, pensioners under the crown during pleasure, or for a term of years, are wholly excluded. Any member, however, who accepts an office of profit under the crown existing prior to 1705, though he thereby vacates his seat, is capable of being re-elected. Contractors with government are ineligible; and it is enacted, that if any person so disqualified shall sit in the House, he shall forfeit 500*l.* per day for so doing; and that if any person having a contract of this nature admits a member of the House to share in it, he shall forfeit 500*l.* to the prosecutor. Again, by 3 Geo. IV. c. 55, no police justice of the metropolis can sit in parliament.

The twelve judges for the time being are disqualified, though, as judges, they are occasionally summoned to, and sit in the House of Lords, but have merely a *consultative* voice there. The vice-chancellor, and the master of the rolls, the judges of the Admiralty, Probate, and Matrimonial Causes courts, and those of the County courts, are also excluded. The exclusion of ecclesiastics from seats in the Commons' house, seems not only to have been a natural result of the presumed urgency of their pastoral duties, but to have reference to the period when their share of those general contributions to the extraordinary exigencies of the state, the business of settling which, as we have already seen, first gave form and consistency to the parliamentary representation in general, was yielded by them as a distinct body. Sheriffs of counties, and mayors and bailiffs of boroughs, as being themselves returning-officers in parliamentary elections, are ineligible for the several districts respectively for which it is their duty to make returns.

The repeal of the Corporation and Test Acts in 1828, and the passing of the Catholic Emancipation Act in 1829, have worked one very important alteration in the constitution of the Commons' House, by removing nearly altogether the widely-operating religious disqualifications which previously existed. The engagement, "on the true faith of a Christian," which the latter act substituted for the oath and declaration formerly required, had no effective operation, except against individuals of the Jewish race and creed. This may now be dispensed with in consequence of the passing of the act, 21 & 22 Vict., c. 49, by a resolution of the house of commons, and Jews now sit in the house.

The property qualification for an English, Welsh, or Irish member was continued by the Reform Acts, namely, for a county member an estate of 600*l.* a year, and for a city or borough member, of 300*l.* The only personal exceptions from this condition were in favour of the eldest sons of peers or of bishops having seats in the House of Lords, and the eldest sons of persons legally qualified to be county members. As regards the Scottish part of the representation, it is worthy of especial remark, that the property qualifications enacted for England within a very few years after the union with Scotland, had never been extended to the latter portion of the kingdom; and that consequently the conditions of suffrage and of eligibility have remained there according to the original constitution of the representative system in both countries, one and the same, excepting only the anciently essential condition of *residence*, which has long been done away with throughout the United Kingdom without any reservation or limitation whatever; and excepting also that the Scottish reform act of 1832 rendered unnecessary for county members the qualification of an elector formerly required. By the act 21 Vict., c. 26, passed on the 28th of June, 1858, all the acts requiring any property qualification in members of parliament were altogether repealed.

Issuing of Writs for a General Election; Election Proceedings and Returns.

An essential and very important part of the representative machinery is that which regards the due transmission from the central to the local authority of the summons to elect, the superintendence of the election proceedings, and the due return from the local to the central authority of the names of the individuals chosen. When the Lord Chancellor, the highest officer of state, has received the written command of the sovereign in council for the summoning of a new parliament, he thereupon sends his warrant or order to the highest ministerial officer acting under him, the clerk of the crown in chancery, to prepare and issue the *writs*, or written authorities for that purpose, to the several sheriffs, whether of counties at large or of counties corporate.

In the early periods of our history, when the shire-motes, or county courts, were held regularly once a month, and the borough courts once a week or once a fortnight, there was no need to incur the trouble and inconvenience of a special meeting of the members of those courts, that is, of the freeholders in the former case and the burgesses in the latter to elect the parliamentary representatives; and accordingly the sheriff was simply required to cause the election of the county members at the next county court, held in the regular course, or at an adjourned meeting of that court, in case such adjournment were necessary in order to allow time for giving due notice of the election. It was not until the importance of the county courts declined, that a different arrangement became necessary; nor was it until the 25th of George III., that it was enacted that the sheriff, on receipt of the writ, should call a *special* county court for the purpose of the election.

The writ, thus addressed under the great seal to the sheriff of a county at large, requires him not only to cause the election of the county representatives, but also of those of each city and borough within his jurisdiction. And accordingly, on receiving this command, he issues a *precept* under his own seal to the head of each municipality enjoying the elective franchise, which precept is to be returned to him within a limited time, together with the name of the person or persons chosen;* in like manner as he himself is bound to return, before a certain day previous to that on which the parliament is summoned to assemble, to the clerk of the crown, from whom he received it, the writ, with the names of the persons chosen, whether as county or as borough members. Such, in brief, as regards the returning-officers and responsible conductors of elections, has been the system from the commencement of the general representation.

In the parliamentary boroughs which had already a municipal or other chief civil officer or officers in whom this function could be appropriately vested, it is so entrusted by the Reform Act. As regards the others, it is provided, that the sheriff of the respective counties shall, in the month of March in each year, by writing under his hand, to be delivered to the clerk of the peace for that county, within a week from its date, and be by him filed with the records of his office, appoint for each of such boroughs a fit person resident therein to be the returning-officer until the nomination to be made in the March following. In case of such person's death or incapacity from sickness or any other sufficient impediment, the sheriff, on notice thereof, is forthwith to appoint in his stead a fit person, resident as aforesaid, to be the returning-office for the remainder of the year. No person so nominated as returning-officer shall, after the expiration of his office, be compellable thereafter to serve again in the same office. Neither shall any person in holy orders, nor any churchwarden or overseer of the poor, be so appointed; nor shall any person so nominated be appointed a churchwarden or overseer during the time he shall be such returning-officer. Any person qualified to serve in parliament is exempted from such nomination as a returning-officer, if within one week after his receiving notice of such appointment he make oath of his qualification before any justice, and forthwith notify the same to the sheriff. In accordance, however, with all previous usage, it is provided that "in case his majesty shall be pleased to grant his royal charter of incorporation to any of the said boroughs named in the schedules of the Reform Act, which are not incorporated, and shall by such charter give power to elect a mayor or other chief municipal officer for any such borough, then and in every such case such mayor or other chief municipal officer for the time being shall be the only returning-officer for such borough; and the provisions hereinbefore contained with regard to the nomination and appointment of a returning-officer for such borough shall thenceforth cease and determine."

The division of both counties and boroughs into convenient polling-districts,—the shortening of the time of polling in contested elections, from the old period of fifteen days to one day in England, Wales, and Scotland, and to five in Ireland,—the restriction of inquiry at the poll into the elector's right to the ascertaining the identity of name and qualification with those contained in the register of voters (thus abolishing the old tediously litigious practice of election scrutinies),—and the limitation of the necessary expense of election proceedings, borne by the candidates or their proposers,—are among the more important of the recent improvements.

Having thus given, we believe, a tolerably just though succinct view of the history and present state of the representative system of the British empire, so far as it can be distinctly shown without continual reference to the other branches of the legislature, we refer for an account of the organisation and operation of the Commons, "in parliament assembled," to a subsequent volume of this work. [PARLIAMENT, IMPERIAL.] There too may be the fit occasion for offering some indications of the future changes in the relative position of the House of Commons as a branch of the legislature, to which the alterations in its internal constitution commenced in 1832 must eventually lead. A word as to the progress of this internal revolution itself must conclude the present notice.

We have seen how the popular representation arose, first as a convenient, then as a necessary appendage to the feudal parliament of the Anglo-Normans. We have seen how, as early at least as the parliamentary settlement of the crown upon the house of Lancaster, that popular representation, under the title of the House of Commons, had become an effective, integral, independent, and solemnly recognised branch of the legislature. We have traced, from that period downwards, the twofold operation, of the crown in undermining this equal and sometimes preponderating independence of the Commons' House, and of that House itself in contracting the limits and abridging the rights of the constituent bodies, until the original constitution of the representative body itself was absolutely subverted. And last of all we have seen that which, in the present day, it is most interesting to consider,—the re-action of an enlarged and enlightened public opinion on the legal constitution of the house. In an historical view it is far less important to examine the merits of the measures of representative amelioration in detail, than to mark the maturity of a new political element which they indicate, and the new line of constitutional progression which they commenced. No matter that the Reform Acts, as they are called, made but a compromise with the exceeding corruptions and anomalies of the old system, and left some of them untouched; no matter that the Commons' House, which in the days of its pristine vigour was democratic in the fullest sense of the term, is still, though somewhat popularised by the recent changes, a highly aristocratic body: we do not the less find in these changes a successful effort of the national intelligence and will, not so much to replace the legislative representation on the basis on which it stood at the close of the 14th century, and which, from the causes we have previously stated, was fixed without any scientific or symmetrical proportioning even of the number of representatives to that of constituents, but to mould it into some shape more accordant with the present advanced state of general information in the great body of the people; to render it, in short, a popular representation in fact as well as in name.

COMMONS, IRISH HOUSE OF. [PARLIAMENT OF IRELAND.]

COMMONS, DOCTORS'. [DOCTORS' COMMONS.]

COMMUNION (the Latin *communio*, the Greek *κοινωνία, koinónia*) is used to designate the uniformity of belief by which a number of persons are united in one denomination or church, as the Roman Catholic, Anglican, or Lutheran communion. *Communio* is employed repeatedly in this sense in the canons of the Council of Elvira (Illiberitanum) A.D. 313. For the examination and comparison of scriptural passages, containing the words *κοινωνία* and *κοινωνεῖν*, the Greek Concordances of the New Testament may be consulted.

Communion is used more especially for the common or public act of sharing or participating in the sacrament, eucharist, or Lord's Supper. Of the origin and use of the word communion in this sense an account is given by Casaubon, 'Exercitat.' 16, § 30. During the first three centuries the communion was celebrated every Sunday. (Bingham's 'Origines Ecclesiasticæ,' vol. v. c. 9.) It was subsequently administered only three times in the year, namely, at Easter, Whitsuntide, and Christmas. By the general council of Lateran, in 1215, it was decreed, in order to check the apparent inclination in many to neglect it entirely, that every one should at least communicate at Easter, that is, once a year. This injunction was afterwards renewed by the council of Trent. For an ample account of the ancient communion service, 'Missa Fidelium,' as well as of the ante-communion service 'Missa Catechumenorum,' we refer to Bingham, vol. v. cc. 1 to 9. There was one form for the clergy, a second for the laity (vol. vi. cc. 2 and 3), and a third and lowest form for strangers or foreigners. Degradation of the clergy to the lay form of communicating in one kind, that is, with bread and no wine, appears to have been an ancient mode of canonical punishment. ('Apost. Can.' c. 14.) The bread appears never to have been omitted: the difference between communicating under one or two species or kinds, as it is termed, being solely in the omission or inclusion of the wine. The communion in two kinds seems to have continued in the Latin church until the end of the 11th century; for in 1099 Pope Paschal II. decreed that little children only should omit the wine, and that the wine alone should be given to those who, from extreme illness, could not swallow the bread. After this period the custom began to prevail of taking the wine by sopping it into the bread instead of drinking it out of the chalice. A letter by Ernulphus, bishop of Rochester, who died in 1124, commends this expedient for several reasons, one of the quaintest of which is, to avoid the profanation of wasting the consecrated wine by the dipping of bushy beards into the chalice. The communion under one species, that is, with bread alone, was authorised in 1415 by a decree of the council of Constance, and was confirmed by the council of Trent in 1562: but, with the exception of the Latin church, all the various sects of Christians have retained the communion under two species. During the first seven centuries the mixing of water with the wine was very generally considered as indispensable to the proper and efficient performance of the eucharistic rite. Justin Martyr, in his 'Apology,' written probably about the end of the 1st or beginning of the 2nd century, observes that the mode of communicating was with a chalice of wine and *water*. It is unnecessary to quote passages from the subsequent fathers in confirmation of this fact. They all appear to have believed the water to be an essential ingredient; and several (Cyprian, 'Epist.' 63, and Athanas. 'in Psal.' 74) assign as the reason of it, that the pure wine of the mystic chalice represents the unmixed nature of God; the pure water represents the nature of faithful Christians; and the commixture of the wine and water represents the union of God and the faithful. A decree of the Œcumenic council, A.D. 691, denounces the Armenians as heretics for celebrating the communion with wine unmixed with water; and the 32nd canon of the council of Trullo decrees the deposition of every bishop or priest who shall omit the water. From the writings of Germain, patriarch of Constantinople; of Cabasilas; of Simeon of Thessalonica; of Balsamon, patriarch of Antioch; of Goar, in his Euchologia; and from the Greek Ritual, it appears to have been a long-established custom in the Greek church to dilute the eucharistic wine with *hot* water, and to administer the mixture hot. To these remarks on the matter of the eucharist, we may add that Epiphanius ('Hæres.' c. 49) and Augustin ('Hæres.' c. 28) speak of an ancient sect of Christians in Phrygia, followers of Montanus, who were called Artotyrites (ἄρτος, τυρὸς), because in the communion, they used not bread and wine, but bread and cheese. (Pluquet. 'Dict. des Hérésies.') Others, the followers of Tatian, in the second century, made use of bread and water without wine, and hence were called Aquarians, and Hydroparastai. (Epiphan. 'de Hæres.' 47; Augustin 'de Hæres.' c. 25; Cyprian, 'Epist.' 63.) This sect is also spoken of by Clemens Alexandrinus, and Chrysostom, and in the 5th century it was revived, with a declaration of motives of sobriety. There appears to have been a custom of communicating with consecrated bread and milk, for it is condemned by the council of Braga, in Spain, A.D. 675. The prevalent report in the first centuries, that the Christians celebrated the communion with flour which was kneaded in or with bread which was dipped in the blood of infants, slain or punctured for this purpose, appears to be applicable only to the Christian sects included under the denomination of Gnostics and Montanists; at least several of the Catholic fathers, in repelling the accusation from the orthodox, distinctly fix it upon these heretical sects. (Epiphan. 'Hæres.' 26 and 48; Philastrius, 'Hæres. Bib. Patr.' tom. 4, p. 13; Cyril, 'Catech.' 16, p. 178; Augustin, 'Hæres.' c. 26; Tertull. l. 2, 'ad Uxor.' c. 5; Baronius, 'Annales,' 120-129.) Until the 7th century the communion bread was that commonly used for food; a particular kind began then to be prepared exclusively for the purpose, of a circular form, and impressed with the sign of the cross. The Greek church adopts a leavened bread, but the Roman church has it unleavened; and this difference has been the cause of much controversy, though it seems easy to decide which kind was used by Jesus, the last supper having been on one of the "days of unleavened bread," when no other kind could be eaten in the land of Judæa. It has been a subject of still greater contention whether the proper posture of communicants is that of sitting, reclining, kneeling, or standing. In the 3rd century standing appears to have been the usual posture. See Euseb. 'Hist.' l. vii. c. 9; Tertull. 'De Orat.' c. ult.; Chrysost. tom. i. 'Hom.' 22, p. 260, παραστῆναι τῇ ἱερᾷ τραπέζῃ. It is also a subject of dispute whether the ancient Agapæ (αἱ ἀγαπαὶ), which some modern sects continue under the name of love-feasts, were identical with the celebration of the eucharist. Probably these friendly repasts, so zealously continued throughout the four first centuries, were commenced or terminated by the act of communion; for they often took place in the churches until A.D. 360, when they were excluded from the churches by the council of Laodicea, on account of their having become scenes of indecorous conviviality. Tertullian, in his 'Apol.' c. 39, minutely describes the proceedings of one which was conducted with propriety. The fathers frequently speak of the consecrated elements being carried home by the communicants, who gave them to the sick, or kept them deposited in their coffers as a charm against evil spirits, or bore them as a viaticum about their persons in travelling, and in voyages by sea. (Cyprian, 'de Caps.' p. 176; Basil. 'Epis.' 289; Ambrose, 'de Obit. Satyri,' t. iv. p. 315; Cyprian, 'de Spectac.' p. 292; Justin. Mart. 'Apol. 1; Baronius, 'Annales,' 57, n. 151.) Among the many purposes to which the sacramental symbols have been applied, we may notice an instance related by St. Augustin ('Contr. Julian.' l. iii. c. 164) of a child born blind who was perfectly enabled to see, after his mother had put upon his eyes a poultice made of the eucharistic bread and wine. In the first centuries it was customary to bury the eucharist with the dead; and though, by the council of Carthage, A.D. 419, and the Œcumenic council in 691, the custom was condemned, it still continued to prevail; and St. Cuthbert and many others were entombed with the consecrated bread on their breasts, as a safeguard against the molestation of demons. To heighten the intensity of a solemn asseveration, a few drops of "the vivifying blood" were sometimes put into the ink with which the signature was written. Thus, in the eighth council of Constantinople, all the bishops signed the deposition of Photius with a pen "dipped in the blood of the Saviour." Thus Pope Theodore signed depositions; and thus Charles the Bold signed treaties of peace. (Baronius, 'Annales,' 648.) It appears to have been always required that, after the serving of all the communicants, any portion of the consecrated elements which might be left should be immediately eaten by the officiating priests; and by the council of Toledo, in 693, the consecration of a prudent and moderate quantity is enjoined, in order to prevent repletion from eating all that remained. Hesychius (in 'Levitic.' l. 2, c. 8) says, that, in the church of Jerusalem these remnants were burned; and Evagrius ('Hist.' l. iv. c. 35) informs us that, in the churches of Constantinople, the priests sent for a school of children to eat up any large quantity of fragments. To the work entitled 'An Inquiry concerning Infant Communion in the first Ages of Christianity,' we must refer for information on that point of the subject (vol. ii. p. 75); and also to the 'Essays on the Eucharist,' by Pierce and Waterland. In the 5th century the communion was sometimes administered by women, and they continued to officiate at the altar in Italy and France until after the 10th century. (Pope Gelasius, 'Epis. 9 to Bishops of Lucania;' 'Epis. Ratherius, Bishop of Verona.') In the 2nd century the eucharist began to be celebrated in the churches with closed doors, with the exclusion of all but the initiated, on which the Pagan philosophers accused the Christians of having adopted the Eleusinian mysteries of Ceres and Bacthus, bread and wine. (Augustin. 'Contr. Faustum,' l. xx. c. 13.) "The fathers," says the Rev. Mr. Abthorp ('Letters on Christianity,' p. 365), "adopted the language of the Eleusinian mysteries, and most incautiously applied it to the Christian worship; especially to baptism and the eucharist." Many learned writers have noticed some remarkable points of resemblance in the Eleusinian mysteries and the Eucharistic rites, such as their being commemorative, and designed to effect a moral regeneration (παλιγγενεσία), or new birth. See Abthorp *ubi supra*; and Casaubon 'in Baronii Ann. exercit.' xvi. p. 478. On the different sorts of communion, see Albaspinæus; Du Pin; Anton. Dominicus; and the very elaborate 'Histoire de l'Eucharistie,' by Arroque.

* In the universities, the vice-chancellor, as returning officer, receives and returns the sheriff's precept of election.

COMPANIES, JOINT-STOCK. [JOINT-STOCK COMPANIES.]

COMPANIES, or GUILDS. It is necessary to recollect the nature of the relation subsisting between the English boroughs and the Norman kings in the period during which they successively purchased their civil redemption, in order to be convinced that the local comfort and welfare of the burgesses were objects of little solicitude to those monarchs—that their primary aim was the securing of the regular, punctual, and willing payment of the stipulated rent, and the ensuring in each locality of so much internal peace and order, at least as to them might seem requisite for enabling the community to perform this stipulation with exactness. Further than this they concerned themselves not at all about the internal regulations of the municipality. Its whole community, now rising again from one and the same level of civil nullity, were at liberty to adopt either the ancient customs and usages of the place as existing before the Conquest, or such others as they might think proper to establish in accordance with the common law of the land. The charters were constantly addressed to "the citizens," "the burgesses," or "the men" of such a city or borough; and the sum of the description of a burgess, townsman, or member of the community of the borough, as Madox, in his 'Firma Burgi,' observes, was this: "They were deemed townsmen who had a settled dwelling in the town, who merchandised there, who were of the hans or guild, who were in lot and scot with the townsmen, and who used and enjoyed the liberties and free customs of the town." The municipal body, in short, consisted of the resident and trading inhabitants, sharing in the payment of the local taxes and the performance of the local duties. This formed substantially a household franchise. Strangers residing temporarily in the town for purposes of trade had no voice in the affairs of the borough nor any liability to its burdens, which, at common law, could not be imposed upon them without admission to the local franchise. The titles to borough freedom by birth, apprenticeship, and marriage, all known to be of very remote antiquity, seem to have been only so many modes of ascertaining the general condition of established residence. The title by purchase was a necessary condition for the admission of an individual previously unconnected with that particular community, in those days when such admission conferred peculiar advantages of trading; and the right of bestowing the freedom on any individual by free gift, for any reason to them sufficient, was one necessarily inherent in the community, for the exercise of which they were not responsible to any authority whatever. The freemen's right of exclusive trading too had some ground of justice when they who enjoyed it exclusively supported the local burdens. Edward III.'s laws of the staple authorised the residence of non-freemen in the staple towns, but at the same time empowered the community of the borough to compel them to contribute to the public burdens; and under these regulations it is that the residence of non-freemen appears first to have become frequent.

The progress of wealth, population, and the useful arts, produced, in many of the greater towns, the subdivision of the general community into *guilds* of particular trades, called, in many instances since the Norman era, *companies*, which thus became avenues for admission to the general franchise of the municipality. In their greatest prosperity these fraternities, more especially in the metropolis, became important bodies, in which the whole community was enrolled; each had its distinct common-hall, made bye-laws for the regulation of its particular trade, and had its common property; while the rights of the individuals composing them, as members of the great general community, remained the same.

Nearly thirty years after the express recognition by charter, of the 15 Edward III., of the power in the citizens of London to make bye-laws, it was, by consent of all the commons of the city ordained that each of the *mysteries*, that is, each of the trading companies, should choose certain persons to assent to and ordain, with the lord mayor and aldermen, whatever they should deem advisable; to elect the mayor and sheriffs; and to give counsel in all cases where it was formerly sought of the commons. This was in the 43 or 44 Edw. III., and was confirmed in the 50th of the same reign: but the common-hall or court of hustings of the whole community still retained the right of re-modelling the municipal legislature; and in the 7 Richard II., the common-council was placed on its present footing by an act of common-hall, passed in the presence of the "immense community," to the effect that, as in such large assemblies things had been done more by clamour than by reason, the aldermen, when, on St. Gregory's day in each year, they were appointed for the year ensuing, should be firmly charged, fifteen days after the said day, to assemble their respective wards, and, by good deliberation, charge them to choose four of the most sufficient persons in their ward, to be of the common-council for the year ensuing, &c., provided that of the whole number no more than eight should be of one *mystery*. Except as to the prescribed numbers, which were not strictly adhered to, this act of common-hall took full effect; the whole administrative powers of the community were transferred to the legislative body, composed of mayor, aldermen, and common-councilmen, all subject to annual election; and the ancient hustings-court fell into comparative desuetude; although, on one subsequent occasion, in the 23 Henry VII., we find the mayor, aldermen, common-council, and commons, acting together as one great common-hall, in accordance with the original constitution.

Such was the natural origin of the courts of aldermen and common-council in the city of London; and how closely analogous was their rise in other communities, is abundantly testified by existing documents.

In those instances where the whole of the citizens or burgesses were numbered in the several trading companies, these, for convenience' sake, sometimes formed the basis of the internal polity of the community, and the election of borough officers and members of the common council became vested in them. London itself presents at this day a remarkable instance of incomplete progression from the household franchise to the adoption of that of the guilds; the inhabitant freemen elect the aldermen and common-councilmen; while the *liverymen*, or members of the several companies (so denominated from the distinguishing peculiarities of costume adopted by each fraternity), resident or non-resident, elect the mayor, sheriffs, chamberlain, and other officers. But, in many boroughs, this basis of the guilds wholly superseded the original scot-and-lot franchise, and in the changes of society which have gradually reduced the guilds from their original position, that thorough substitution has been one constantly growing cause of unfair exclusion. The richest and most influential persons, too, being generally chosen by the inhabitants at large to the highest places in the municipal councils, were often tempted to seek the perpetuation of their authority without the necessity of frequent appeals to the popular voice, and even to usurp powers which it had not delegated at all. Such usurpations however were often vigorously resisted by the community at large; and the contests were sometimes so violent and obstinate as to lead to bloodshed. But in course of time, the Crown itself, so long indifferent to the details of municipal arrangements, found sufficient motives for encouraging these endeavours of internal parties to form close ruling bodies, irresponsible to the general community.

In many towns, as still in London, it was necessary, in order to complete his title, that the party should be first admitted a member of certain guilds or trading companies of ancient institution within the borough, and still preserving various degrees of connection with, and subordination to the municipal corporation; a practice which seems to have been formerly still more prevalent. The derivative title conferring a right of admission to these guilds was usually of the same kind as that by which the municipal corporation itself was entered. These guilds were also accustomed to admit by purchase; but such purchasers neither acquired nor could convey any absolute right to admission into the municipal corporation. Occasionally, an incorporated guild has continued to exist after its connection with the municipal corporation has been almost or wholly dissolved.

The titles from birth, marriage, and apprenticeship, were very various in different places. In some, the right by birth was enjoyed only by the children of freemen born within the borough; in others, by children of freemen wherever born; in some, the father's admission at any time conferred the inchoate right on all his children wherever born; in others, only on those born after, and in many, only on the first son born after his admission. Less variety is found in the nature of the title which a freeman's daughter or widow must possess, to enable her to convey the privilege. The right by apprenticeship has usually accrued by service under indentures for seven years to a freeman within the borough: service at sea has generally been considered in the light of service within the borough where the vessel belonged to its port: in some boroughs having trading companies, the binding and service must be to one of the company in the trade peculiar to that company.

COMPANY, in military affairs, is the body of men which constitutes one of the principal divisions of a battalion of infantry, and which corresponds to the troop in a regiment of cavalry. The strength of a company in the regiment of artillery is 120 men, in the guards and line 80 men. In each battalion there is one which is called the grenadier company, and another the light company; and these are called flank companies from their stations, which, when the battalion is drawn up in line, are at its extremities. The grenadiers acquired that denomination from the grenades, or small shells, which they were trained to throw by hand into an enemy's works; and the light companies were so called from their being required to act as the skirmishers of the battalion. Every company of the line and militia is commanded by a captain, under whom are a lieutenant and an ensign, besides the non-commissioned officers; formerly in the regiment of Artillery, the Rifle Brigade, the corps of Royal Engineers and Marines, and the Fusilier regiments, each company had, instead of an ensign, a second lieutenant. The rank of second lieutenant has now, however, been done away with, being changed to that of ensign in the case of the Rifle Brigade and Fusilier Regiments; and to that of lieutenant in the Royal Artillery, Royal Engineers, and Marines. The rank, however, does not carry the pay of lieutenant with it to any besides the established number; those who would under the former regulations have received the pay of second lieutenant, still only receive it.

In France, the first formation of bodies of men under the denomination of companies, may be said to have taken place in 1373. [CAVALRY.] But the institution in that country of what approaches nearer to the present signification of the word, occurred in 1557, when Henry II. divided a French legion into fifteen bodies of 400 men; each of which, except the two first divisions or companies, was commanded by a captain, a lieutenant, and an ensign, besides two serjeants and eight corporals. Those two companies were considered as being immediately under the command of the colonel himself, and therefore had no officer of higher rank than lieutenant. This regulation seems to have been followed in the British service, since formerly in each regiment there were two, called the colonel's companies, which were commanded by lieutenants only, who, however, were by courtesy entitled captains.

It is observed by Grose, that probably from the time of the Conquest the English infantry was divided into corps, consisting of 1000 men, which were subdivided into hundreds and tens. And he remarks that in the list of the army engaged at the siege and battle of St. Quentin, in 1557, each company is stated to consist of 100 men, and to be commanded by a captain, a lieutenant, and an ensign, as at present, besides a serjeant, a harbinger or quartermaster, and a drummer.

COMPASS, HISTORY OF THE. The knowledge of the directive power of the magnet was unknown to the Greeks, the Romans, and to European nations generally till late in the 12th century; and does not appear even then to have been brought into common use for nautical purposes. It has however been so known and so used in China, Japan, India, and Arabia from periods of high antiquity. Doubts, indeed, have been often expressed of the validity of the claims of the Chinese, and of the authenticity of the dates attributed to the notices of it in the grand annals of their empire; but the most careful examination of the Chinese claims does not warrant our scepticism on one point or the other. The Jesuit missionaries who went to China in the beginning of the 17th century, were of course little likely to admit the high antiquity claimed by those annals without rigorous inquiry; nor, without evidence of great force, to give up in any degree, even implicitly, the chronological authority of the Vulgate Scriptures: yet this was not only the case, but upon their return they unanimously agreed in the conviction that those records were authentic, and several of them published that conviction to the world, at no small degree of risk to their reputation for orthodoxy. No exact translation into any European language of the passages from which they drew their accounts of the directive properties of the magnet, had, however, been given till the year when Klaproth published his 'Lettre à M. H. Humboldt sur l'Invention de la Boussole,' at Paris; and a translation of the passage in question has been again given in English by Mr. Davies in his 'Early History of the Mariner's Compass,' published in the 'British Annual for 1837.' The circumstance, from its incidental mention, seems to give greater authority to the passage. It relates to the date 2634 years before our era.

"Houang-ti punishes Tchi-yeou at Tchou-lou.

"The Waï-ki said: Tchi-yeou bore the name of Khiang; he was related to the Emperor Yan-ti. He delighted in war and turmoil. He made swords, lances, and large cross-bows to oppress and devastate the empire. He called and brought together the chiefs of provinces: his grasping disposition and avarice exceeded all bounds. Yan-ti-yuwang, unable any longer to keep him in check, ordered him to withdraw himself to Chao-hao, in order that he might thus detain him in the west. Tchi-yeou nevertheless persisted more and more in his perverse conduct. He crossed the river Yang-choui, ascended the Kieou-nao, and gave battle to the Emperor Yan-ti at Khoung-sang. Yan-ti was obliged to retire and seek an asylum in the plain of Tchou-lou. Hiuan-yuan (the proper name of the Emperor Houang-ti) then collected the forces of the vassals of the empire, and attacked Tchi-yeou in the plains of Tchou-lou. The latter raised a thick fog, in order that by means of the darkness he might spread confusion in the enemy's army. But Hiuan-yuan constructed a *chariot for indicating the south, in order to distinguish the four cardinal points;* by means of which he pursued Tchi-yeou and took him prisoner. He caused him to be ignominiously put to death at Tchoung-ki. The spot received, from this circumstance, the name of the plain of the broken curb."

Other Chinese accounts vary as to language and as to circumstances relating to the personal character of Tchi-yeou; but they all agree in the statement respecting the *Tchi-nan* (or chariot of the south) being constructed by the emperor on that occasion; and it is remarkable that the very name by which the instrument is denoted, like every thing else Chinese, is retained almost unvaried from the earliest period of their history down to the present times.

Though numerous other passages of various dates speak with equal explicitness of the use of the compass for land purposes, yet no mention of the use of the magnet for *navigation* occurs in any of their books that have come to the knowledge of Europeans, till the dynasty of Tsin, which lasted from the year A.D. 265 to 419. It is in the great dictionary Poi-wen-yeu-fou; and it is there stated that "there were then ships directed to the south by the needle." Mr. Davies contends that this passage rather refers to the magnitude of their ships and the extent of the voyages which they performed, than to the introduction of the needle into marine affairs. In the 9th century two Mohammedan travellers travelled into Arabia, an account of whose journey was published from an Arabic manuscript (which bears internal marks of being written as early as the close of the 11th century) by Eusebius Renaudot, at Paris, in 1718. In this it is stated, that the Chinese at that period (the 9th century) traded in ships to the Persian Gulf and the Red Sea; and though the compass is not mentioned, it is utterly improbable that the Chinese should have known the directive property of the magnet, and have *used* it on land for thirty centuries, and yet not have employed it at sea. It was known on the Syrian coast before it had come into general use in Europe, as is obvious from the following passage from a manuscript witten in 1242, by Bailak Kibdjaki, which is very explicit in its description of the nautical compass: "We have to notice, amongst other properties of the magnet, that the captains who navigate the Syrian Sea, when the night is so dark as to conceal from view the stars which might direct their course according to the position of the four cardinal points, take a basin full of water, which they shelter from wind by placing it in the interior of the vessel; they then drive a needle into a wooden peg or a corn-stalk, so as to form the shape of a cross, and throw it into the basin of water prepared for the purpose, on the surface of which it floats. They afterwards take a loadstone of sufficient size to fill the palm of the hand, or even smaller; bring it to the surface of the water, give to their hands a rotatory motion towards the right, so that the needle turns on the water's surface; they then suddenly and quickly withdraw their hands, when the two points of the needle face north and south. They have given me ocular demonstration of this process during our sea-voyage from Syria to Alexandria in the year 640" (of the Hegira). An older passage than this might have been quoted, did the limits of our article allow of amplification; but this has been chosen on account of the distinctness of the description. When we consider the jealousy with which all knowledge was guarded by its possessors, especially that of *commercial* value, we cannot but admit that the use of the compass must have been very common at a period when a passenger was initiated into the complete knowledge of the mode of magnetising the steel needle, as well as the mode of using it.

In 1260, when Marco Polo returned from his travels in Cathaï, he is believed to have brought a knowledge of the compass, as well as other Chinese inventions, back to Europe with him; but there is no known authority for this opinion that can lay claim to authenticity. It is certain, however, that before the close of the 15th century, when Vasco de Gama found his way round the Cape of Good Hope, the pilots of the Indian Seas were expert in the use of sea-charts, the astrolabe, and the compass.

A passage extracted from the 'Landnamabok' of Are Frode, who lived about the close of the 11th century, has been brought forward by Professor Hansteen to prove the use of the magnetic needle for purposes of navigation at least as early as that date, in Norway; "*for in those times seamen had no loadstone in the northern countries.*" But this passage is most probably an interpolation by the continuator of the chronicle, which view is supported both by the remark of the editor, Finseus, of the chronicle itself, as well as by the circumstance of the whole passage not being found in three different manuscripts. Its authentic origin cannot reach higher than the 14th century. ('Brit. Ann.,' p. 296.)

The mariner's compass is, however, minutely described by Guyot de Provins, who wrote his satire entitled 'La Bible,' about the year 1190. This has usually been assumed to contain no indication that the mariner's compass was a recent discovery or only little known in France at the time of the composition of the satire; but Mr. Davies considers that the minuteness of the description itself, as well as other collateral evidence, proves clearly that it was an instrument at that time not only not much known, but a total novelty. Guyot, a minstrel by profession, had probably seen it in use during the Crusades, to one of which most likely he had previously attached himself. At all events, Cardinal de Vitry and Vincent de Beauvais, both Frenchmen, and both Crusaders, writing at a later period by a quarter or half a century than Guyot, speak of it as a great curiosity which they saw in the East, and as a thing perfectly new in Europe would be spoken of. There is not hence the slightest foundation for the belief that it was used by European seamen at so early a period, though there can be but little doubt that by the middle of the 13th century it had come into partial use and into general knowledge; since, in one of the songs of Gauthier d'Epinois is an *allusion*, which no one would have made had not his auditors been familiar with the magnetic needle.

It was long contended, that the inventor of the compass, as a *nautical* instrument, was Flavio Gioja, a native of Amalfi, near Naples, and the date given by the Italians is from 1300 to 1320. It will be obvious, from what we have already said, that there is no foundation for this opinion; and independently of this, the authority of the statements themselves is invalidated by an appeal to the facts which are affirmed in proof of it, as may be seen either in Klaproth's letter or in the 'British Annual.' Before this assigned period, even the 'Trésor' of Brunetto Latini (the master of the Divine Dante) bears evidence that the compass was not a rarity. It is, however, highly probable that Gioja greatly improved the compass, either by its mode of suspension, or by the attachment of the card to the needle itself, or in some other important particular.

The French have laid claim to the discovery of the compass, or at least to the attachment of the card to the needle, from the circumstance of the north point being marked with the *fleur-de-lis;* but in the absence of all distinct evidence on this point, it is much more probable that the view taken by Mr. Davies is correct,—that the figure is an *ornamented cross,* and originated in devotion to the mere symbol; though, as he observes, as the compass undoubtedly came into Europe from the Arabs, the *fleur-de-lis* might possibly be a modification of the *mouasala* or dart, the name by which the Arabs called the needle.

The discovery of the variation of the needle was generally (before the appearance of Cavallo's 'Treatise on Magnetism') attributed to Columbus, but since that time it has been assumed as being very early known. [DECLINATION OF THE NEEDLE.]

The dip of the needle, or its *inclination,* was the undoubted discovery of an Englishman, Robert Norman, a nautical instrument maker at Wapping, who published an interesting account of the course of his experiments in 1594, under the title of the 'New Attractive.' [DIPPING NEEDLE; MAGNETIC INTENSITY.]

The *variation of declination* is also an English discovery, having been made, as is well authenticated, by Stephen Burrowes, of Limehouse, and fully determined by Gillebrand, professor of geometry in Gresham College; and the diurnal variation of the declination also unquestionably belongs to another Englishman, Mr. Graham, about 1719.

England, in the person of an intrepid and accomplished navigator and marine surveyor, Capt. Flinders, claims another discovery of great and enduring importance. In his memorable but unfortunate voyage in the "Investigator," he first detected the cause of errors in the variation of the magnetic needle as depending on the direction in azimuth of the ship's head. The value of this has been extensively felt among nautical men, and considering that the announcement of his discovery was made ('Philosophical Transactions' for 1805) during the six years he was unjustly imprisoned and detained at the Mauritius by the French governor, De Caen, and that on his release, with greatly impaired health and pecuniary resources, the numerous experiments made under his directions at Sheerness, Plymouth, and Portsmouth, fully confirmed his original views, the name of Flinders will stand forth prominently in nautical history as one of the most persevering (though unrequited), as he was one of the most accurate, among modern surveyors, and scarcely second to Cook among modern navigators.

COMPASS, AZIMUTH, is a compass with plain sights, and with vertical wires attached to it in such a manner as to be moveable round a vertical axis independently of the compass-card. A pointer shows angle which the position of the telescope, or sights, marks out on the card, that is, the bearing of the object towards which the sights are directed. This angle is the azimuth of the object, when the correction for magnetic variation is made. But when the bearings of two objects are measured, the correction need not be applied in merely determining the difference of bearings, since the error affects both equally.

When observations in azimuth requiring greater accuracy are taken, an instrument called a Theodolite is used. [AZIMUTH; THEODOLITE; CIRCLE.]

COMPASS, THE MARINER'S. A magnetic needle balanced on a pivot will, subject to corrections for the variation of the magnet on account of terrestrial influence, point out the true direction of north and south. A card bearing the points of the compass, and unalterably attached to any apparatus, such as a globe, will therefore afford the means of adjusting it north and south, if the centre of the card be made the pivot of a magnetic needle. In the mariner's compass, however, it is usual to affix the needle to the card, pointing towards its north and south point, so that the card travels with the needle; and if a pointer (fixed with respect to the ship) mark out the point on the edge of the card which lies in the line drawn through the pivot parallel to the plane which symmetrically bisects the ship, the bearing of the ship's head is shown by the part of the card to which the pointer directs for the time being. Instead, however, of a pointer being used on board ship, it is usual for a mark to be drawn upon the inner surface of the compass-bowl, a line between which and the centre of the compass being always parallel to the ship's keel. To ensure the horizontality of the compass-card, the cylindrical box or bowl in which it is enclosed, is supported in a hoop at opposite points, by pins projecting from it, so as to allow the box to revolve inside the hoop. This hoop is supported in the same manner on pivots, the line of which is at right angles to the first pivots; so that between the rotation of the compass-box in the hoop, and the hoop itself, the former can always find its position of equilibrium, which is the horizontal position. The small oscillations of the apparatus are immediately destroyed by the friction. The apparatus is then said to be supported on gimbles, or gimbals.

By whom the suspension now generally used was invented, is altogether unknown from any document or other evidence. The suspension of the whole machine itself on two circles, whose suspending diameters are at right angles to each other, is, however, on all hands admitted to have been English, though we are still ignorant both of the person who invented it or the period of the invention. It appears to be traditional evidence on which the opinion rests; but a tradition in which rival nations agree, bearing on an invention which would be honourable to any one to have a power to claim, can hardly be supposed an erroneous one. Voltaire, in his essay on 'Universal History,' seems to confirm the English claim, when he admits that "the first who certainly made use of the compass were the English, in the reign of Edward III." He speaks of a Carmelite friar of Oxford named Linna, an able astronomer of those days, having sailed as far as Iceland, when he drew charts of the North Seas, which were afterwards made use of in the reign of Henry VI. But Voltaire should have applied his assertion to an improved form of it, rather than to the circumstance of its use for the first time. Still, even in England, in the time of Queen Elizabeth, the construction was very rude in its execution.

The mechanism of the compass is a subject affecting so largely the commercial interests of Great Britain, that not only does the safe transit of the goods of the merchant depend on its proper adaptation to the principles on which magnetism can be available to the sailor, but much of the safety of ships of war, in particular, will be involved in the accuracy of working shown by these instruments. Our unnautical readers will easily understand the importance of a correct manufacture of the compass when the following case is assumed in illustration: Let two ships of war, of equal size, shape, and fittings, and commanded respectively by pilots of equal skill, attempt, in hazy weather, to enter the Thames or some other estuary difficult of approach. Let their compasses be from the same maker and alike, and of ordinary construction, as now used in H.M. navy. It is quite possible that one ship may reach her port in safety, while the other may suffer total wreck; for the secret of the safety or loss of the ships may even have depended on the following simple circumstance: In the one case, the wary old quarter-master at the "con binnacle" shall have attached a piece of packthread to the compass-rim, by lightly jerking which occasionally the compass-card will have been kept more "alive" on its needle point, or have moved more freely on its pin; while the quarter-master in the other ship may have thought such precaution uncalled for, and the sluggishness of the compass have caused an erroneous impression as to her courses. Some remarks, therefore, as to form and manufacture are called for, having for their object the development of a compass system calculated to avert not only existing inconveniences, but those calamities which the introduction of iron into ship-building in the merchant service, and the increased armament with heavy ordnance (and especially the adoption of Armstrong's steel gun) into her Majesty's service afloat, would, if unheeded, entail upon the navies of the maritime kingdoms of the world.

So much has been written and said upon the compass of late years, so many of our ablest philosophers have devoted their attention to the improvement of the mariner's compass, that, seeing the results of their labours in the complexity and variety of form which have still further complicated the question in the eyes of the unscientific, it will be well to review slightly the past, taking, however, the present condition of the compass as the best and most profitable subject for our consideration. A slight glance at the history of the compass will assist us in our conclusions, inasmuch as the experience of centuries will have its bearing upon and considerably influence them.

The most simple and primitive form of the compass appears to have been either the magnetised needle thrust transversely through a cornstalk, and left floating in a screened basin of water [COMPASS, HISTORY OF THE], as used on the Syrian shore; or the small Chinese needle, resting, just below its centre of gravity, upon a needle-point fixed on a wooden stand. The greatest amount of steadiness on the one part, and activity of the needle on the other, seem to have been obtained, so far as regards mere form. (We, for the present, leave intensity out of the question.) But it must be remembered, that steadiness might amount to sluggishness, and activity might merge into inconvenient oscillation. A modified form, therefore,—one combining both qualifications,—has, through many centuries, been the navigator's *desideratum*. It is curious to notice how varied have been the attempts to produce a good and unobjectionable compass. Still more are we astonished and humbled to see in the most recent (so-called) "improvement" the very principle of the floating compasses, as described in 1242 by Bailak Kibdjaki!

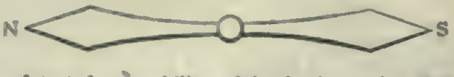
Scarcely any modification of form had occurred, certainly for the three centuries previous to the time of Richard Norman of Limehouse, in 1590. Norman appears to have introduced some change, in what, however, one would imagine his only *improvement* to have been, the adding of a counterpoise to the ancient Chinese form of needle, rendering it, by means of a weight sliding on the needle or bar, susceptible of adjustment in removing it from one part of the earth's surface to another. [DIP.] Probably few successful attempts had, till very recently, been made to examine the magnetic conditions and changes to which the needle was subject, or the advantages of one form of the needle itself over another. The only improvements seem to have been those which insured greater nicety of construction. Our countryman Michell subsequently increased the efficacy of the needle by his invention of what was called the double touch, which symmetrically diffused the magnetic influence in the two arms of the needle; and early in the present century, Captain Kater directed his attention to the imparting of the greatest amount of directive intensity by experimenting largely on the form and temper of the metal of the bar. Several men of science, and among them Professors Barlow, Lloyd, Arago, Faraday, Wheatstone, Airy, &c., and also Messrs. Biot, Hauy, Coulombe, Dr. Gowan Knight, Dr. Scoresby, Sir Wm. Snow Harris, and others, from the delicacy, beauty, and success of their experiments, created an interest in the matter never before felt; but these researches were, with some exceptions, rather confined to the properties of the bar or needle than to the precise form of compass to be used on shipboard. It is however proposed to limit our considerations in this article rather to the mechanical form of compass than to abstract principles, which will be referred to in their proper place under the word MAGNETISM.

While it is admitted by many (and among them by Sir Wm. Snow Harris) that the sensibility and delicacy of the primitive *small* needle of the Chinese are quite surprising, and while Michell and many others approve of the *very light* steel bars of the Chinese to be used as compass-needles (because magnetic power increases in a less degree than the friction arising from increase of weight), it is singular that those now in use are quite of opposite construction. As many as, or more than, four or five bars being now attached to the same card, and resting on the same needle-point, their weight, as might be expected, increasing friction to such a degree that even agate caps soon *wear out* and become useless. Mr. Stebbing, an eminent optician at Southampton, partially obviates the inconvenience of this by substituting the ruby. Few individuals gave more attention to magnetism and to the accuracy of form in the needle than the late Dr. Scoresby; but it appears that no improvement in shape resulted from his long continued labours. Dr. Gowan Knight, the first appointed principal librarian of the British Museum, a man of persevering research in science, who wrote a century since, described the form of compass-needle used in his day by the merchant service as formed of two steel plates bent at their centres and meeting at their ends, and forming the two poles, in this manner:—

Fig. 1.

But he found that when the temper of the metal in each piece differed, the directive intensity was not in the axial-line of the mass, nor did polarity at all times exist precisely *at the ends* of the needle. At the same period he describes the form of bar as used in H.M. navy to have been as under:—

Fig. 2.



In this he detected a capability of its having no less than six poles, while the greatest available directive force can only exist when there are two. His investigations of the question established the still admitted fact, that the form of needle best adapted to the mariner's compass was the regular parallelopiped, being a straight bar with its narrow dimension placed vertically. Dr. Knight also found that the mode of suspension adopted by the Chinese,—namely, the suspension of the needle at a point a little below its centre of gravity,—was the best, as conducive to sensibility. He moreover recommended the use of such a needle *without central perforation*. Dr. Knight's form of needle was for a long time adopted in H.M. ships; and, as Sir Wm. Snow Harris, with undoubted propriety, in his excellent 'Manual of Rudimentary Magnetism,' suggests, "it is still worthy of serious attention." Perhaps in no one branch of science has more valuable time been bestowed in the construction of an instrument than in the attempt to perfect the needle and mariner's compass. Sir William Snow Harris has, in a form of compass which bears his name, adopted the suggestions of Norman in 1590, as regards the compensating slides on the bar, and also the opinions of Dr. Knight in 1750, with reference to the form of needle; but its chief excellence is in the amount of directive force imparted to it. He also adopts the *light* form of needle, but not to the extent found in a Chinese instrument.

Enough has been said to show that the precise form and arrangement of the mariner's compass has long been a question of public anxiety; and still more must its consideration press upon us when to the new armament of ships and the increased use of iron afloat (as already noticed), must be added the increased amount of iron carried as cargo, and the circumstance of increased speed of ships which brings them more suddenly into danger; these beset navigation with difficulties only to be surmounted by a well-founded confidence in the form, and *simplicity in the mode of using* a well-made compass, and this can only be attained by careful investigations and unfettered and disinterested conclusions.

It is worthy of remark here that to such an extent has the public mind at times become embarrassed with this consideration, that in 1854 a panic on the Liverpool 'Change nearly excluded for several days the iron ships of the port from freight engagements. It arose from the following circumstance: The late Rev. Dr. Scoresby, with that honesty of purpose and plainness of elucidation for which he was remarkable, informed the merchants of Liverpool of various discoveries as to the causes of local disturbance in iron ships, such discoveries having however a tendency to cast doubt and distrust around that on which hitherto the sailor had relied as his faithful conductor through the pathless oceans of the globe. [LOCAL ATTRACTION.] The insidious workings of the magnetic influence, then for the first time made known to the commercial world, and this too under the sanction of a meeting of the British Association, naturally alarmed the ship-owner, appalled the merchant-captain, and lent its aid towards general confusion. Although the discoveries of Dr. Scoresby are of absorbing interest to the philosopher, and have assisted others in their laboratories, yet to the mariner or the ship-owner these subtle workings of the magnetic current ought to have presented very little *real* difficulty, as was promptly shown in a published address by Mr. Saxby to the ship-owners of Liverpool, and also by the judicious and timely appeals to them by Mr. Grantham, a very eminent marine engineer of that town. The effect of this on the compass question was, the almost immediate production of such a variety of forms of the instrument as were calculated, it was supposed, to pacify the ship-owners; but it actually left the ship-captain burdened and bewildered with novelties and perplexities which even now, in a great measure, render the correction and use of the compass, notwithstanding its importance, the least satisfactory, the most anxious, and the most tiresome of all his work at sea. This competition, however painful in its early operation, had, in a national point of view, a salutary effect. It loudly evoked the hidden talent of officers in the mercantile marine. It aroused their energies, and demanded of them something beyond attention to the mere routine in which they had been trained. Ship-captains soon found among their numbers many men of sufficient talent to grapple with the compass question, and that large and respectable body, relying on themselves rather than on men of reputed science, began to judge for themselves as to the merits of the various toys placed into their binnacles by credulous owners; and many an absurd, though presumptuous and specious form of compass has already been by them consigned to oblivion; many ingeniously contrived instruments, good in themselves but totally unfit *for sailors' use*, have gradually sunk or are yet gliding visibly into disrepute. With that promptitude, however, which characterises Liverpool merchants, soon after the announcement made by Dr. Scoresby, a Compass Committee, seconded by the authorities at the Board of Trade, was formed, and a vast collection of facts speedily poured in from those who were interested, and measures were taken to assist navigators, which will be clearly and more properly detailed under the head of LOCAL ATTRACTION in this work. But nothing resulted from their really praiseworthy and indefatigable investigations, calculated to modify the generally existing form of mariner's compass: *nothing new* appears to have been suggested by that body indicative of real improvement in the instrument.

Although we must not in this article enter far into the question of local attraction, yet as its causes have led to some modifications in the form of compasses to facilitate corrections for deviation, &c., it is necessary to notice that the Astronomer Royal, having long turned his powerful mind to the question, announced to the world a theory of local attraction which involves the necessity for soft iron as a part of the compass-correcting arrangement. No greater proof of the difficulties which surround the mariner's compass as a nautical instrument can be adduced than the fact, that, although now some few years have passed since Professor Airy first gave to the world his really simple and elegant theory for correcting by magnets and soft iron, his opinion remains unseconded and *unadopted* by the Admiralty, by whom correcting magnets are rejected altogether, from extreme and irreprehensible, but possibly overstrained, prudence. It is not improbable that a number of the fallacious methods of correction of the compass produced of late, have so deluged the authorities at the Admiralty with suggestions thereupon, as to somewhat blunt the intelligence, and thereby obscure the truth, *even when offered by the Astronomer-Royal himself*. It must also be remembered, and indeed it is a fact well-known to the writer, that many merchant-captains who have had their compasses corrected in port by the use of fixed magnets, have found such error and inconvenience arising therefrom (on account of subsequent changes in the magnetic condition of the ship), that rather than endure the annoying discrepancies and perplexities consequent on their use, they have pitched their correcting magnets overboard altogether; preferring to encounter the magnetic dangers of the voyage with a single well-made compass which they *did* understand, to tampering with changeable and vacillating agents and appliances which were above their comprehension. Such may account for the authorities at the Admiralty rejecting the use of correcting magnets altogether.

Taking even Professor Airy's theory of moveable adjusting magnets and soft iron as an instance, how few merchant-captains, unaided by a mechanically convenient correcting apparatus, could follow a learned discussion on so intricate a science as that of magnetism (however valuable in itself); much less could they use the mathematical formulæ necessary for its application to the mariner's compass. It remains to state that a practised compass-maker, a Mr. John Gray, of Liverpool, an optician of talent well known in all the principal ports of Europe, after study and experiment on an extended scale in which he believed he could corroborate physically the theoretical assumptions of Professor Airy, contrived a compass arrangement which, apart from all invidious selection, and from a sense of public duty, finds an illustration in this article. Several other forms for correction of the compass-needle exist, and each has its advocates, but the following sketches of Gray's compass arrangement give an idea of the form in which the Astronomer-Royal's suggestions are being carried out.

Fig. 1.

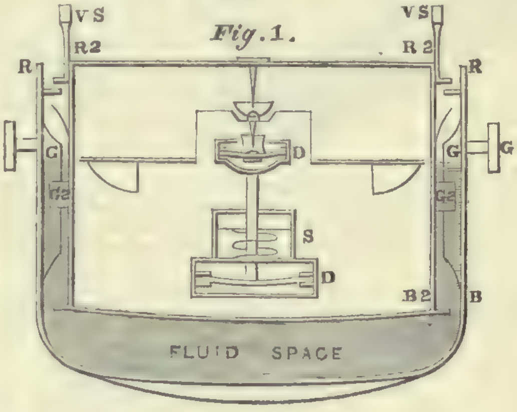


Fig. 2.

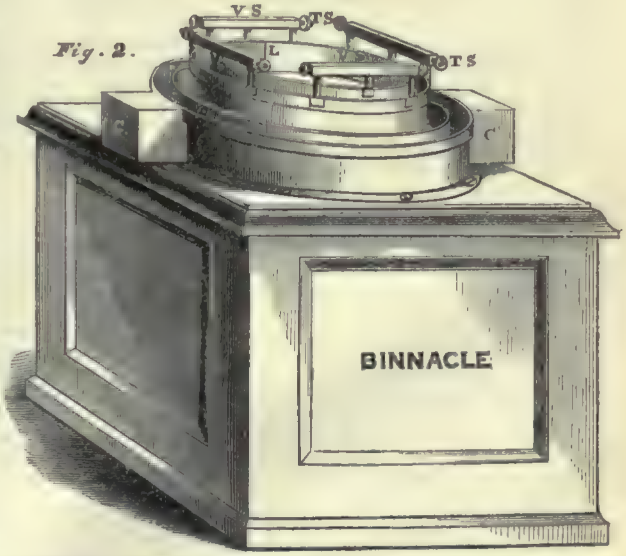

B, Outer bowl, containing fluid, in which, B 2, inner bowl is floated; R and R 2, Rims of outer and inner bowls; V S, Springs to keep the bowls in central position with each other; T S, Tangential screws to adjust the bowls to their centres; G and G 2, Guides to prevent rotatory motion; L, Lubber's point; D, Elastic discs; S, Spiral spring; C, Chain boxes for soft iron; G 3, Gimble.

The above has, moreover, an interest from being the form of apparatus used on board Her Majesty's yachts; and without compromising that independence of thought and rigid impartiality which ought to characterise this work, we may remark that it is said by the Astronomer-Royal publicly to be "perfectly correct," as to the principles under which it is constructed, and "entirely satisfactory" to him. The one property which (while there might seem to be some complexity in the mode of suspension) distinguishes this apparatus from others, is the facility with which the adjusting magnet can, under very simple printed instructions from the maker, be altered in position, so as to compensate the changes produced from alteration in the magnetic condition of the ship.

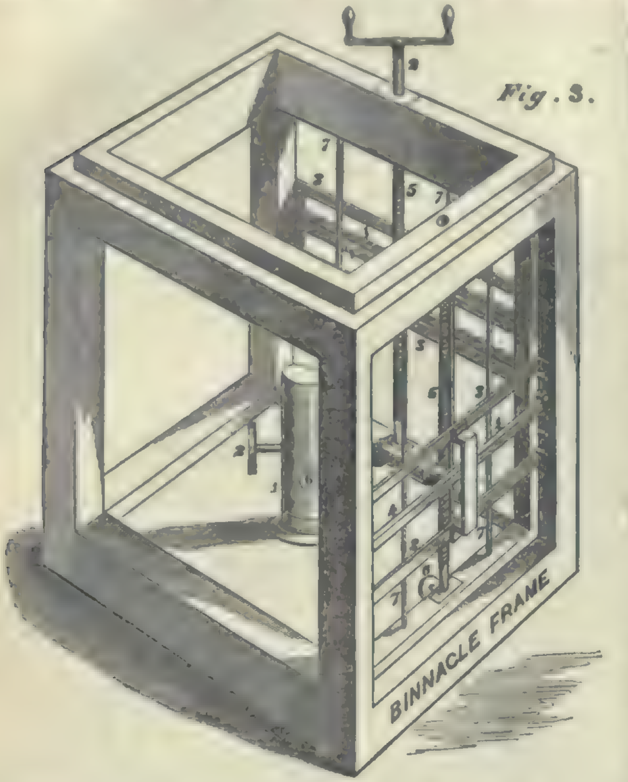

Fig. 3.

1, Cylinder containing vertical magnet; 2, Keys to raise and lower the magnets; 3, Frame in which the magnets are placed; 4, Magnets; 5, Vertical screws for raising and lowering the magnet frame; 6, Screws to prevent the vertical screws altering their position; 7, Guides to the magnet frame.

Nothing is intended herein to disparage the beautifully constructed and excellent compasses made by those whose names have been mentioned as some of the principal makers of this country. A very elegant form of compass, in which the magnet is attached to a vertical metallic zone, and the whole inclosed in a glass globe, has been invented recently by a Mr. Gowland, of Liverpool. It is for practical men to satisfy themselves thoroughly if the three grand *desiderata* of the compass be fulfilled in any one instrument; these are:—

1. Steadiness, without sluggishness.
2. Activity and sensibility, without oscillation.
3. Facility for correction under local attraction, without complication.

COMPASS CORRECTION. Under the word Bearing, some notice has been taken of the most recent improvements in the method of using the compass for nautical purposes.

It is ordinarily supposed by landsmen, that with a well-made compass, and a knowledge of the variation thereof, as depending on terrestrial changes [Variation], and this to be applied on either hand of any given point, according as the magnetic needle deflects towards the east or west from the true pole of the world, or the meridian, a navigator might find his way to distant parts of the earth; but the need of correction from other causes, daily or hourly in some ships, gave rise to and constitutes what has been so long called and agitated as the compass question.

The navigator's desire at sea is simply to know on *what angle from a meridian*, or true north and south line, *his ship is sailing*. But before he can arrive at a satisfactory conclusion as to his correct course, the various channels through which local attraction affects his compass have to be estimated; in other words, he must free his compass bearing from all casual local magnetic influences; and this constitutes the work of *compass correction*. If such were easily performed, on merely knowing the deviation [Deviation], an ordinary additive or subtractive operation would suffice; but it unfortunately happens that the quantity of iron used about a ship, and especially in a steamer, presents a combination of disturbing forces so intricate in their relations, that *no man of experience should rely on any mere system of instrumental correction, independent of actual observation of a heavenly body*, much less will he rely *solely* on a correcting card, or correcting magnets. It may here be well to explain so clearly the present state of things, that the difficulties which have hitherto clouded the brow of the master mariner, plunged him into uncertainties and unnecessary labour, depriving many a weather-beaten and storm-tossed mariner of his nightly rest, may, in those whose intelligence really befits them for their duties, be *totally set aside;* and that ships may henceforth be navigated with a confidence and security profitable alike to their owners, their crews, and the public.

The system of correction at present adopted in Her Majesty's navy is the following: A line-of-battle ship, having on board nearly 500 tons weight of iron guns, shot, and shell, being moreover a screw steamer, with all her massive machinery, an immense iron funnel, iron water tanks, iron anchors, iron cables, &c., is fitting for sea, off one of Her Majesty's dockyards, say for example, Sheerness, either before or after the usual trial trip (generally before), and it is thought necessary to swing her for compass correction. Where no distant and conspicuous object is in sight, this is done by sending a trusty officer on shore at an assumed station, say at the Isle of Grain, with an azimuth compass. The ship is then turned about, so as to bring her head to every point of the compass, and by comparing simultaneous observations (made during the time of swinging) between the ship and the station, and the station and the ship, some notion can be formed of the local attraction on board: thus, if the officer on board at a certain moment sees (for example) his assistant at the station on shore bearing due west by ship's compass, and the assistant on shore at the same time sees the officer on board bearing, not east, the opposite point, but E.S.E., there must be, in one or both instruments, a total deviation of two points, or 22° 30′; but as the compass on shore is carefully placed, so as to be beyond the influence of any local attraction, the deviation is always attributed to some magnetic disturbance on board. These deviations, as found on each point, are carefully noted and collected, and form what is generally called a correcting card. Various methods have been proposed for the registering of these deviations; perhaps nothing more simple and ingenious has been offered than the one by Sir Archibald Smith, in the form issued by the Admiralty to each of Her Majesty's ships. The swinging of a ship, then, is nothing more than a mode of finding the error of her compass at a certain moment; but as there are other methods of ascertaining this so important a fact, it is necessary to consider *which of the many is the most accurate, simple, and convenient* in application and practice.

The swinging of a line-of-battle ship is a work of labour, time, and expense; it often occupies three or four days, the employment of about 300 men, the wear and tear of two, three, or four hawsers, the letting go and weighing two or three heavy kedge anchors;—all this is necessary in swinging a ship of the line. But the advantage of ascertaining precisely the state of such ship is paramount, and we should spare no time, labour, or money, if a permanent result could thus be obtained. It unfortunately happens, however, that any change which may occur in the magnetic condition, or even position of the iron on board, such as the training of a gun, the firing of a broadside, lighting the fires of the engine, moving the ponderous funnel up or down, and various other unavoidable operations on shipboard, may so affect the compass as to render a correcting-card, obtained at *one time* with so much labour, totally useless at *another*. It is true that some ships have been found to undergo very little changes during long periods; but, on the other hand, it is equally well known that steamers which have preserved a remarkably equable state of magnetic condition for years, have suddenly shown disastrous changes. To mention only one case out of hundreds, in support of this assertion—an iron steamer, belonging to one of the principal companies of Liverpool, which had shown great uniformity as to local attraction for several years, was, in 1857, proceeding down Channel, under the command of a distinguished officer, who was on his 73rd voyage past that coast. It was a pleasant, calm, hazy evening, and the commander supposed, from her standard compass, that the ship was heading fairly for the Longship's light. But just after sunset a cry suddenly arose from the look-out man, of "Rocks ahead!" and to his amazement the experienced commander found himself running stem-on to the Stones in St. Ive's Bay. It was afterwards found by the writer of this, that the local attraction on board must have varied 16 degrees after leaving Liverpool. The ship and crew were barely saved from destruction; an instance of the high importance of the subject now under our consideration; for we have *no means of ascertaining the amount of liability in any particular ship to vary her condition, hence the doubtful value of any correcting-cards* whatever. The subtle disturbing element may at any moment, from unforeseen causes, accumulate in this gun, or that range of shot, or in some particular iron knee, or chain, or iron stanchion; so that the wary master or commander may suddenly, and at any time, be deprived of that in his so-called correcting-card, the loss of which would necessarily entail much anxiety, until opportunity presented itself of checking the state of the compass by a celestial observation.

As an important public question is deeply involved in this scrutiny of the practice of swinging a ship, an operation shown to be not only expensive and troublesome, but *absolutely dangerous if too much reliance be placed upon it*, it may reasonably be asked why we permit fallacies to exist in our system. In such a cause, it behoves every man of science who would assist the navigator to cast aside all prejudices and mere "customs," and, taking the simple *facts* of the case, attempt a total revision of the subject of compass correction.

But what of the check referred to, as deduced from celestial observation? The question of correction must be viewed under two aspects, namely, the *accuracy* and *labour* in the means employed. As a question of spherical trigonometry, its accuracy is mathematically sufficient; and, as regards labour, there are two ways of working, namely, by logarithmic *calculation* and by *construction*. The calculation of an azimuth is the resolution of a spheric triangle, in which certain things are given to find others: as in the following example, in which it was possible to use the horizon.

Suppose a ship to be in latitude 51° 30′ N., when the altitude of the sun's centre was 40° 25′, the sun's declination at the same moment being 20° 2′ N.: required the sun's true bearing and the error of the compass, the bearing of the sun by compass being S. 79° 39′ W.:—

Sun's declination . . .	20° 2′		
	90 0		
Sun's Polar distance . . .	69 58		
Latitude	51 30	Log secant .	0·20585
Sun's altitude	40 25	" secant . .	0·11842
Sum	161 53		
½ Sum	80 56½	" cosine .	9·19711
Diff. between ½ Sum and P. dist.	10 58½	" cosine . .	9·99198
The true azimuth .	S. 69° 39′ W. =	Log sine square	9·51336
By compass . . .	S. 79 39 W.		
Error of compass . .	10 0 West.		

Or supposing the horizon obscured, and an altitude impracticable, take the following example:—

A ship in latitude 10° 20′ N.; sun's declination, 22° 14′ S.; the time of day, 1h. 44m. 17s.; the sun's bearing, N. 162° 3′ West: required the true azimuth and compass error?

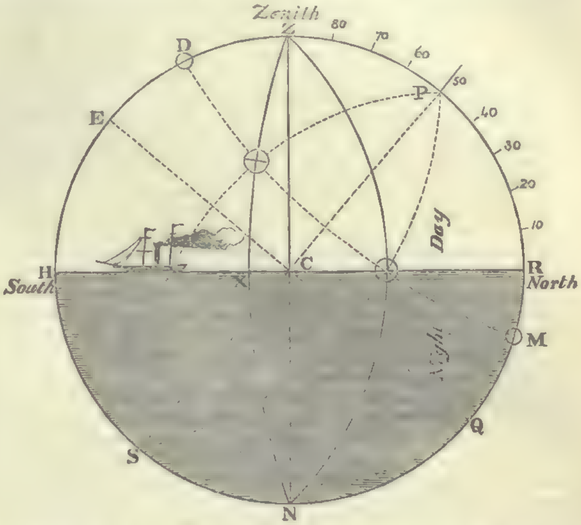
	H. M. S.				
Time . .	1 44 17				
Half . . .	52 8	cotangent	0·63548	cot.	3·63548
	90° 0′				
Sun's declination	22 14				
Polar distance .	112 14				
90° 0′					
Co. Lat. 10 20	79 40				
Sum . . .	191 54				
Difference . .	32 34				
½ Sum . .	95 57	secant	0·98439	co. sec.	0·00235
½ Diff. . . .	16 17	cos. .	0·98222	sine .	9·44776
	88° 34′	tan. .	1·60209	tan. 50° 37′	0·08559
	180 00				
Supplement .	91 26				
	50 37				
Sum, N. . .	142 3 W. = True azimuth.				
N. . .	162 3 W. = Sun's bearing by compass.				
	20 0 W. Error of compass.				

Such are the calculations in each case, and they are shortened when altitude and time are both known. Better even would it be to use in this manner a few extra logarithms daily, than to depend on a correcting-card. But there is another and more simple method, not generally known, of solving a spheric triangle with sufficient accuracy for an azimuth, where the nearest degree is enough, because one cannot steer a ship to within less than a degree or two: it is by *construction* of the spheric triangle. This process, however, would have its inconveniences, although it requires only a plane scale and a pair of dividers or compasses. But these inconveniences have of late been totally obviated by the invention of the spherograph [SPHEROGRAPH], in which, having any three elements of a spheric triangle, the others are found without any calculation, and in a very few seconds; indeed, the Astronomer Royal has given his written opinion that "*for the special purpose of determining azimuths to correct a compass, he thinks the spherograph is excellent.*"

In anticipation of the word SPHEROGRAPH, a sketch of the instrument as it appears when finding an azimuth will in this place be sufficiently illustrative.

In the annexed figure the sun is represented as being just on the horizon, the dark lines of the drawing represent the upper sphere, and the dotted ones those of the under sphere as *seen through* the upper transparent one, both spheres being moveable on the centre C.

Suppose the latitude, say 50° N., to be represented by P R (equal to the height of the north pole of the heavens above the north part of the horizon), and the oblique circle P O S to represent the hour circle for 7 P.M., and the small circle D ⊕ O M to represent the sun in its distance from the equator (E Q), or, as it is called, the declination. For all nautical purposes the line D ⊕ O M may be called the sun's path in the heavens for that day. Now, the part of the circle R must have been moved on its centre C so as to place it 50° (the required latitude) from P: on the under sphere *no other movement is required:* but we see at a glance that the sun would be at M at midnight, at O when rising or setting, and at D when on its meridian. Hence, the degrees being all printed on the spherograph so as to enable all distances to be *read off*, no further *measure* or construction could be required, and we should in this instance find that C O on the horizon would measure the rising amplitude and O R the rising azimuth; and C being the east and R the north part of the horizon of the instrument, the sun would rise at about N.E. by E. Suppose it were required to correct the compass at any time of the day, say at 9 A.M., I should select the 9 A.M. hour circle P ⊕ S, as drawn on the under sphere of the spherograph, and notice where it crosses the parallel of declination D M at ⊕; and any vertical circle (suppose Z ⊕ N) which, passing through the intersection, cuts the horizon (as at X), would show the bearing in azimuth as measured at H X; and as H is at the south part of the horizon and C is at the east, C X would be very nearly east by south: if the compass showed by it that the sun was at the same time (for instance) E.S.E., the compass would have an error of one point.



It seems then that a possibility exists of totally avoiding accidents dependent on compass errors, and by a means sanctioned and approved by the Astronomer Royal; and although changes in magnetic condition cannot be foreseen and prevented, we in reality seem to be able, *by merely turning a transparent card on its centre*, and at any time, or at any part of the world, and by a process which occupies about ten seconds of time, when any heavenly body is visible, *and without requiring any observation for altitude*, to place an effectual check upon a compass.

In order therefore to put the question in a plain and available form for mariners, the following is proposed as a system applicable at all times to any compass, and on board any ship, be her magnetic condition whatsoever it may: and as this method of ascertaining a true azimuth from celestial observation is *totally independent of the horizon*, it is available in a few seconds whenever any heavenly body is visible, even in hazy weather, and is therefore much more convenient and expeditious, as it must be more accurate, than any swinging of a ship:—

1. As a mariner always knows his latitude and declination to the nearest degree, and his apparent time to the nearest minute or two, let him, when desirous of merely checking his compass, find at once the sun's true azimuth [BEARING] by the spherograph (or by construction or calculation, at pleasure), and compare the result with his compass bearing of the sun's centre.

   If his ship be at anchor, and he wishes to examine into her general local attraction, let him, *while she is swinging with the tide*, take the bearings of the ship's head as she comes to the several points of the compass, noting against each observation the apparent time at which it was taken: then let him seek against each of those times in the spherograph the corresponding true azimuth of the sun (the whole is done by one movement of the upper card of the spherograph on its centre), and by comparison the whole condition of the ship *for that day or period* is shown, and that too without the usual labour and expense and detention of the vessel during compass correction. As many as 300 bearings have been taken by the late secretary of the Compass Committee at Liverpool, while a ship has been swinging with the tide even in so quick and strong a river as the Mersey.

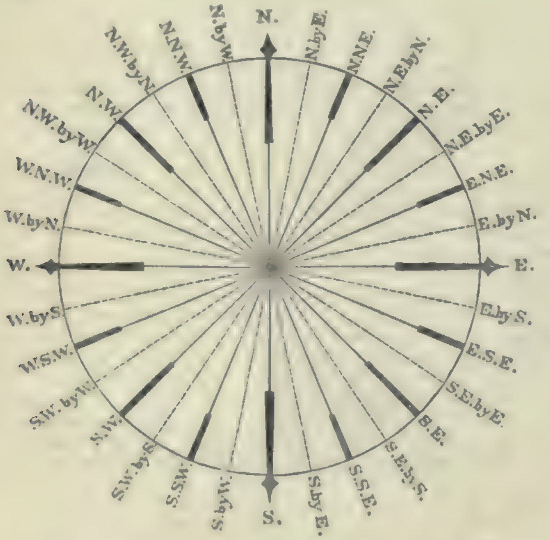
2. Either register the error so found in one of the admiralty forms of graphic delineation (Sir A. Smith's), or adjust the shifting magnets and soft iron by the astronomer royal's method, by the assistance of Gray's or any other apparatus for effecting this object. [Compass, The Mariner's.]
3. Let the ship occasionally yaw a few points from her course at least once a day, using the spherograph, and in case of suspected bad weather, up to the last moment at which a heavenly body is visible.

By following the above plan the compass need no longer be a source of anxiety to an officer of a ship; for instead of his having, as at present, to depend on an erroneous system of adjustment made in port perhaps many months before, or by the working of an azimuth, for which he cannot always get an altitude, he can dispense with both these methods, and avoid all calculations or complexities whatsoever, whenever any heavenly body is visible. If by night, he would use the star's distance in time from the meridian of the place as if it were in the spherograph apparent time.

From the extreme simplicity, infallibility, and rapidity of the above method, it may be suggested that, in passenger over sea steamers, the compass ought to be checked *once in every watch;* for this purpose a common compass, fitted with Captain Robertson's patent "deviation detector" [Bearing], would, with the spherograph, be all-sufficient.

COMPASS, NOTATION OF. The notation of the mariner's compass is very simple. If we divide a circle into four equal parts, each of the points which separate those parts may be called cardinal. Pliny called one of these the *cardo mundi*, or the pole of the world, meaning the north pole. Another ancient author speaks of the *cardo cœli*, or the pole of the heavens, meaning also the north pole; while Quintilian speaks of the *four* as the *quatuor cardines mundi.* Hence, by common consent, the north, east, south, and west are called "cardinal points."

The formation of the compass card will be easily understood by the following:—



Let N.E.S.W. represent the cardinal points. The point midway between them is formed by combining the letters; thus, taking the quadrant or quarter of a circle which lies between N. and E., the intermediate point will be called N.E. If we halve this distance, N. and N.E., we call the middle point N.N.E. If we halve now the distance, N. and N.N E., we call it N. b. E. (or north by east, or north *towards* east, for any further combining of letters would be inconvenient). In like manner we divide N.E. and E., and the intermediate point will of course be E.N.E. (the nearest cardinal point always stands first when we combine the letters); and again, halfway between E.N.E. and E. would be E. b. N. (or east towards north). It need only to be remembered that the cardinal points, *and* the midway points between them, such as N.E., S.E., N.W., S.W., always have the word "by" or "b." in the points next to them. The other three quadrants are formed in precisely a similar manner. We thus find the circle divided into 32 parts or points; and as the whole circumference of a circle is divided into 360 degrees, 360 divided by 32 will give 11° 15′, or 11¼ *degrees*, as the angle which each point makes at the centre of the compass.

When using a compass card, the observer should always consider himself as *at the centre of it*, and not outside the circle; for the centre of the compass card represents the point of the earth on which he is standing, and the visible horizon may be considered to be represented by the outer rim of the card, on which the degrees are generally marked.

The direction in which an object lies is called its bearing. [Bearing.]

COMPASSES. This term we suppose to be synonymous with *compassers*, instruments by which we compass or go round a space. We shall here only give such a general notion of different kinds of constructions as will perhaps suggest the most convenient for any particular purpose.

1. *Common Compasses*, or *Dividers.*—These are simply two pointed legs on a common pivot, for transferring distances. For drawing a circle the lower end of one of the legs is removed, and its place supplied by a holder for a pencil, or by a steel pen.

2. *Hair Compasses.*—One of the legs has a part attached to the upper part by a spring, so that by means of a screw a very small motion may be given to the lower end. It is convenient for very accurate dividing, but must be used with care.

3. *Triangular Compasses.*—These have three legs and two pivots, so that the three points of a triangle can be at once transferred. This is useful only in rough work, as the instrument is difficult to handle.

4. *Proportional Compasses.*—These consist of two dividing compasses with a common pivot, which, when open, present vertically opposite angles; consequently, the intervals between the points of one and the other are in the same proportion as the legs of one to the legs of the other. The pivot is a clamping screw, which can be transferred along the interval between the pairs of points, and a scale points out how to adjust the instrument so as to alter any line, or surface, or solid, in a given proportion. These compasses sometimes have an apparatus for slight adjustment; but on the whole we consider it as an instrument for rough work.

5. *Beam Compasses.*—This instrument is a cylindrical bar, perpendicular to which, with clamping screws, slide a point and a pencil. The use of it is to describe large circles, or to measure large distances, the common compasses being very liable to slip when opened very wide. It is a safe and sure construction.

6. There is a method of describing a small arc of a very large circle, as follows: An elastic rod of metal is furnished with a rigid bar, on which it can be drawn up by screws, so that the rod shall form an arc, the chord of which is a part of the bar. This may be adjusted so as to pass through three given points nearly in the same straight line, and though the curve then described by guiding the point of a pencil along the rod be not exactly an arc of a circle, yet, for all small flexures, it will come sufficiently near for practical purposes.

7. *Caliper Compasses*, or callipers, are compasses intended to measure the calibre or diameter of round bodies, and are formed with curved legs, knobbed instead of pointed. Being opened until the body to be measured can only just pass through them, the distance between the two internal extremities of the knobs is of course the diameter of the body.

Many other species of compasses have been constructed, but the above are the principal ones in common use. [Elliptic Compasses.]

COMPLEMENT, that magnitude which, with another, makes up a given magnitude. This is the general meaning of the term; but the most usual specific uses are as follows: Complements of the parallelograms about the diagonal of a parallelogram: through a point in the diagonal draw parallels to the sides; the whole is then divided into two parallelograms on the diagonal, and two which only touch the diagonal at one angle. The latter pair are called by Euclid complements to the former.

The complement of an arc or angle is the arc or angle by which it falls short of a quadrant or a right angle.

The complement of a logarithm is the number by which a logarithm falls short of 10: thus comp. log. 2 is 10 — ·30103 or 9·69897.

The arithmetical complement of a number is the number by which it falls short of the next higher decimal denomination. Thus, ar. co. 936 is 1000 – 936, or 64; arith. comp. of 83 is 100 – 83, or 17. Beginning from the left, subtract every figure from 9, up to the last significant figure, which subtract from 10.

For the complement of life, see De Moivre's Hypothesis.

COMPLEMENTARY COLOURS. [Light.]

COMPLUTENSIAN POLYGLOTT. [Bible.]

COMPOS, or NON COMPOS, MENTIS. [Insanity.]

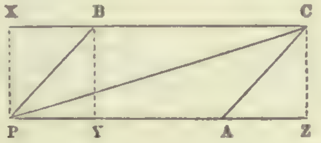
COMPOSITE ORDER. [Column.]

COMPOSITION. In the gradual progress of mathematical language, this word has acquired a general meaning, as follows: Any one magnitude is said to be compounded of two others, when it produces the same effect as the other two put together. For instance, if we increase a length in the proportion of 3 to 7, and then increase the result in the proportion of 2 to 5, the original line is increased in the proportion of 3 × 2 to 7 × 5, or of 6 to 35. Hence the proportion of 6 to 35 is said to be the proportion compounded of (out of) the proportions of 3 to 7 and 2 to 5.

The effects of which it is in our power to form a distinct conception are of two kinds: 1. Those in which there are only two kinds imaginable, and those two diametrically opposite, with one neutral intermediate state. 2. Those in which the diametrically opposites have an infinite number of intermediate gradations. Loss or gain of money is an instance of the first; change of direction of the second. If, at the rate of an inch to a shilling, gains were measured northward from a given point, and losses southward, we could immediately make it a necessary consequence that the balance, if any, is represented by a line northward or southward, according as it is for or against. But draw a line eastward, and it will readily be admitted that such line will not present itself in any necessary connection with a sum lost or gained, or neither lost nor gained. For if the latter, why should a line eastward be preferred to a line westward, or in any other direction?

An immense number of modes of composition will readily suggest themselves, in which addition and subtraction are the processes by which composition takes place. If I go three miles northward, and then two miles farther, I go in all 3 + 2, or 5 miles northward. Other modes, as in the instance first given, will suggest themselves, in which multiplication and division are the compounding processes, and so on ad infinitum. These are all cases in which magnitude only is concerned; but whenever we have both magnitude and direction, it is plain that we have now both magnitude and direction to consider in the effect. If I go a mile northward and then a mile eastward, the whole effect, as to direction, will be, that I go to the north-east; as to magnitude, that I go not two miles, but only $\sqrt{2}$ miles, or 1·414 miles very nearly. Here is an instance in which the components are represented in magnitude and direction by two sides of a triangle, while the total effect is similarly represented by the third side. In the article Centre will be found various instances in which the meaning of that term implies the point at which a single action must take place, which will produce the same effect as a number of different actions produced on a number of points.

In mechanics, we have to consider the combined effects of different velocities, pressures, momenta, rotations, &c., communicated at the same moment of time to the same body. In all, the law of composition is found to be as follows:—



In what sense soever the actions at P can be represented in magnitude and direction by PA and PB, in that same sense can the joint effect be represented by PC, the diagonal of the parallelogram, in both magnitude and direction: or PA and AC being the actions (AC being equal to PB in magnitude and direction), PC, the third side of the triangle, is the united action. Thus, if at the same instant we communicate motion to P in the directions PA and PB, with velocities PA and PB per second, we thereby merely communicate to P a velocity PC per second, in the direction PC. The same holds of momenta and pressures; and even if we give P two separate rotations, which would separately carry it round the axes PA and PB in angles per second which are in the same proportion as PA and PB, the joint effect is a rotation round the axis PC with an angle per second which is to the angle of PA (or PB) as PC is to PA (or PB).

We have here not to prove these things, but only to illustrate the word composition. But this we must remark, that our preconceived notions will never allow us to say that A is the effect of P and Q, and B of R and S, unless the application of P, Q, R, and S together will be the same in effect as that of A and B together. We shall show that this necessary condition of our notions of cause and effect is preserved in the method of composition just described. Let PX, BY, and CZ be parallel to each other; then, if our law of composition be general, PB is the effect of PX and PY. Therefore PX, PY, and PA should be together equivalent to PC. But AZ is equal to PY, and PZ is therefore equivalent to PA and PY. Therefore AC should be the effect of PZ and PX, which we immediately see it is, being as much the diagonal of PXCZ as it is of PBCA.

As another, and a very curious instance of composition, we shall notice the following: Suppose x and y are to be measured, and both are subject to error, every error entailing loss in proportion to its magnitude, and causing equal loss, whether it be an error of excess or an error of defect. Suppose also that the errors are of such a kind that the average of any number of measurement is more probably right than any other. Let a and b be the sums which it would be equitable to pay for insuring x and y, that is, which should be given to any one who would agree to bear the loss on x and y separately. The sum which should then be given to one who would bear the total loss arising from the possible error in $x + y$ is not $a + b$, as might at first appear, but $\sqrt{a^2+b^2}$, or the hypothenuse of a right-angled triangle of which a and b are as the sides.

Our limits will not allow us to enlarge on this subject; we shall add the two following remarks.

1. The fact of the law of composition being the same both for velocities and pressures, has caused many writers on mechanics to confound the two, as if the one proved the other, which is neither true, nor even *very* probable. And other writers on mechanics, while proving this general law, that actions which can be represented by the two sides of a triangle produce an action which can be represented by the third side, have restricted the proposition, and seem to imagine that what they prove is true of *forces* only. This, with great deference to such a writer, we conceive M. Poisson to have done in the well-known proof at the beginning of his mechanics, a work which we may take this opportunity of saying, we hold in higher estimation than any other elementary mathematico-physical work whatsoever.

2. The difficulties of negative quantities in algebra arose from a want of generality, which gave rise to the attempt to express composition by addition only or by subtraction only, where either addition or subtraction might be requisite; and the difficulties of impossible quantities arose out of a similar deficiency, bearing the most complete analogy to trying to compound in magnitude only, in cases where both diversity of magnitude and of direction should have been considered.

COMPOST. [Manure.]

COMPOUND, that which results from composition. [Composition.]

COMPOUND ADDITION. [Addition.]

COMPOUND INTEREST. [Interest.]

COMPOUND QUANTITIES [Arithmetic], quantities in which more than one unit is employed, as in 2 pounds, 3 shillings, and 6 pence: 2 miles, 3 yards, and 4 inches.

COMPOUND RADICALS. A term applied in chemistry to those combinations of elements which act towards oxygen, hydrogen, and acids, as simple elements. [Organic Radicals.]

COMPOUND RATIO. [Composition; Ratio.]

COMPOUNDING OF A FELONY. [Felony.]

COMPRESSIBILITY OF WATER. [Elasticity.]

COMPURGATOR. In the middle ages a practice prevailed, derived from the canon law, of permitting persons accused of certain crimes to clear themselves by purgation. In these cases the accused party formally swore to his innocence, and, in corroboration of his oath, twelve other persons, who knew him, swore that they believed in their consciences that he stated the truth. These twelve persons were called compurgators. (Ducange, 'Juramentum.') This proceeding appears to have existed among the Saxons, and, in process of time, it came into use in England in civil cases of simple contract debts. [Wager of Law.] The ceremony of canonical purgation of clerks-convict, which was nothing more than the formal oath of the party accused, and the oaths of his twelve compurgators, continued in England until it was abolished by the stat. 18 Eliz. c. 7. [Benefit of Clergy.] (Blackst. 'Comm.,' Dr. Kerr's edit., vol. iii., 364; iv., 434.)

COMPUTATION. We need not tell those who are acquainted with the existing treatises on arithmetic, that in no one instance do they pretend to give any mode of forming good habits of computation. The beginner, after receiving instructions as to what is to be done in the several great rules of arithmetic, is allowed to manage the details as he can.

The mere mechanical art of computation, apart from arithmetical reasoning or application to subjects of interest, is no very lofty exercise of the mind. A wonderful degree of proficiency in it can be attained by many who find connected reasoning almost an impossibility; and on the other hand, some of the first among mathematical discoverers have hardly arrived at more than the expertness of an ordinary schoolboy. It is one of those arts among many which are accessible to all who begin with a determination to conquer difficulties, and a power of arriving at methodical habits: no person who, after beginning in the right way, is obliged to confess a total failure, has any ground to suppose that he could master a common manual art: he may be a genius, but nothing could make him a weaver. That we may not frighten any one of the thousands who are miserable computers after going through years of school discipline, and whose minds are too well made to allow them to flatter themselves that they were above it, it is but fair to say that very few are allowed to begin in the right way. Every merely mechanical business must be learned by a sufficient repetition of the most purely elementary steps. A discipline of the mind may be taken up at the wrong place, and still be a discipline, though not so perfect as it might have been. But in what is merely art, nothing can compensate for the want of habit of operation duly learned at the proper time. Now computation is only an art: its elements are a small number of acts of memory: its details consist in a still smaller number of operations, each of which, by itself, is of the utmost simplicity.

Many readers will suppose us, in speaking of the elementary rules of arithmetic, to mean addition, subtraction, multiplication, and division, as given in the books: but we should as soon think of saying that the elementary operations of a journeyman tailor's business are the making of coats, waistcoats, and trowsers. The rules just named are the perfection of computation, not its commencement: he who can do them all with ease and accuracy is a calculator. The fundamental operations of which we speak are to those elaborate processes just what threading a needle and drawing a stitch are to the making of a coat. We can carry the comparison still further: and its justice is not accidental, but the necessary consequence of the resemblance of all mechanical operations. We do not say that a workman who is capable of joining two pieces of cloth together with strength and neatness is a finished tailor: he cannot therefore choose cloth, cut out cloth, imitate fashions, but he can follow directions, and he is the man who actually makes the coat. Nor do we mean that the person who can merely perform the four rules is a complete arithmetician: he cannot know how to apply those rules, he has not learned how to think of their uses. But, under directions, he can really manage the last and executive process of any mathematical inquiry. Until he is something better, he is but a tool in the hands of others, but no one thinks the less of tools because they cannot work of themselves.

Is this then, we shall be asked, all that you propose, namely, to describe addition, subtraction, multiplication, and division? We answer, yes, and on these simple grounds, that nothing more is wanted, and that in what we have to say upon them, we shall touch the reason why so many persons are incapable of and disgusted with arithmetical process. There are but few who find much difficulty in comprehending what is to be done in a question of arithmetic: but there are many who find that, however clearly they may see the way, there is a heavy and broken ascent between them and the answer. The figures will not come right, there is nothing but mistake after mistake: and though everything else is gained, the result is not. Few of those who are thus perplexed are aware that nothing is wanting but attention to the elementary processes with a better method than a beginner invents for himself: every one knows that books and teachers give no method at all.

The following system of exercises constitutes the whole of what is necessary. The degree of attention with which each is to be practised must depend upon the circumstances of the learner's case. Each one contains a difficulty which most persons will suppose they could avoid, some in one manner, some in another. Their several suppositions are true; and it is just as true that the trouble and risk with which an infant learns to walk upon its feet could be avoided; some could continue to crawl, others could contrive to walk on their knees; all would get on in a certain manner. Any person who is determined to succeed, and who has reason to know that his method has not answered as yet, should try our plan with the faith of a learner. But we can promise him no success unless he will make up his mind, from the outset, entirely and at once to abandon every habit which we condemn, and to adopt every mode which we prescribe: and this, though it should seem to him that what he has to take up is more difficult than what he is to leave off. He may take any time, and must not be discouraged by finding that the new operations are at first longer than the old ones. He must continually attempt more and more rapidity, remembering that quickness of operation will never come of itself by practising with deliberate caution. Slow and sure is better than quick and wrong, no doubt, if one or the other must be the end of it; but *quick and sure* must be the motto of an arithmetician. All very correct computers that we have seen have been rather rapid workers: we believe the reason to be that those who cannot acquire rapidity give it up in disgust.

1. Presuming that the learner can count one, two, three, &c., as fast as he can speak the words, he must then try if he can do the same backwards, as fifty, forty-nine, forty-eight, forty-seven, &c. He must then practise counting forward—by two at a time, as in 2, 4, 6, &c., 1, 3, 5, &c.—by three at a time, as in 1, 4, 7, &c., 2, 5, 8, &c., 3, 6, 9, &c.—by four at a time, as in 1, 5, 9, &c., 2, 6, 10, &c.—and so on up to 11 or 12 at a time. The same should be done backwards, as in the following by sevens, 90, 83, 76, 69, &c. In doing this he must not use any description, either vocal or mental: it must not be 22 and 6 are 28, 28 and 6 are 34, &c.; but 22, 28, 34, &c. These various processes should be carried to or from 100 at least.

2. Proceed to form with rapidity the number which must be added to a given number to make up the next number which ends with a given digit. Thus, one of the questions asked, at its fullest length, is "Given 38 and 4, how much must be added to 38 to give the next number that ends with 4." But all that must be repeated, orally or mentally, is "38 and six are forty-*four*." Write down a row of numbers, as in

7 2 9 6 3 2 8 4 1

and practise thus:—72 and 7 are 79, 29 and 7 are 36, 96 and 7 are 103, 63 and 9 are 72, &c.; taking 72, 29, 96, &c., for the successive lesser numbers, and 9, 6, 3, &c., for the successive unit figures of the greater numbers.

3. Endeavour occasionally, in the exercise immediately preceding, and in those which follow, to fix the thoughts particularly upon the *tens* of the result. It will generally happen that the units are immediately to be written down and discarded, while the tens are to be retained in memory. Practise repeating a number, so as while repeating it to write down the units and think of the tens: thus, in 76, at the moment of writing down 6, think of 7.

4. Learn the multiplication table up to 12 times 12, but not with the usual practice of wording all the results, as in "7 times 8 make 56," "4 times 5 are 20," &c. The table must be so learnt that the two factors suggest the product instantaneously. Thus, 8 and 9 must give 72 the instant they come together in the mind; and so on. Take a row of numbers as before, and looking at the successive pairs, repeat the products. Thus, 2 9 8 7 4 3 5, &c., is to suggest 18, 72, 56, 28, 12, 15, &c., as fast as the words can be spoken. Those who have been accustomed to learn the multiplication table from the half of it, always putting either the greater factor first, or else the lesser, must now accustom themselves to the whole: 5 and 9, or 9 and 5, must suggest 45 with equal ease.

5. Augment the last exercise as follows:—Having three digits learn to pass in thought immediately to the product of the first two augmented by the third; thus 7, 9, and 8 must lead to 7 times 9 increased by 8, or 71. Take a row of figures, as before, say, 2497163, &c., which must be made the means of suggesting immediately 17, 43, 64, 13, 9, &c. The usual repetition, "twice 4 are 8 and 9 are 17," &c., must not be tolerated for one moment.

6. Acquire the power of combining the fifth and second exercises as follows:—Having four digits, learn to add the third to the product of the first and second, and to pass on to the next number which has the fourth in its unit's place. Thus, with 7, 8, 5, and 0, think of 61 (7 times 8 and 5), as in the last exercise, and as in the second, get "61 and 9 are 70." Repeat only as much as is in the last phrase, dealing with the first three numbers by the habit acquired in the last exercise. Thus, with the row of numbers 19728663, &c., should be rapidly suggested—16 and 6 are 22, 65 and 3 are 68, 22 and 4 are 26, 54 and 9 are 63, &c.

7. Having four numbers, deal with the first three as in the fifth exercise, and then repeating the result, add the fourth. Thus, from 2, 7, 5, 8, get 19 and 8 are 27. Thus, the row of figures 7984361, &c., must give—71 and 4 are 75, 76 and 3 are 79, 35 and 6 are 41, 18 and 1 are 19.

8. Having a digit and a number of two places, learn to arrive speedily, and with few words at the number of times which the second contains the first (when not more than 9), and at the remainder. Thus, "7 in 53, 7 times and 4," "8 in 29, 3 times and 5," &c.

A person who really desires to become a good computer *must* arrive at the power of performing these exercises easily, quickly, and accurately. It is possible to dispense with them, and it is possible to dispense with rules and numerals altogether and to use pebbles. But we are very confident that when these exercises are once made very rapid and safe, the computer has gone through nine parts out of ten of his training: he can walk, and will soon learn to find his way. The common error lies in imagining that learning to find the way is learning to walk.

We now take the four rules, insisting on the details of the mode of performing each of them, and presuming the usual process to be known.

Numeration.—Learn to distinguish tens, hundreds, &c., not by the places in which their digits come, but by the numbers of places which come after those places. Instead of connecting thousands in the mind with the *fourth* place, connect them with *three places cut off*. Thus 176493 has 1764 hundreds, 176 thousands, &c.

Addition.—Add as in exercise 1; thus, if the figures were to be 7 2 3 4, &c., it should not be 7 and 2 are 9 and 3 are 12 and 4 are 16, &c., but 7, 9, 12, 16, &c. Dwell upon the tens to be carried, in writing down the units. In the following question, every word that should be repeated, orally or mentally, is written down, and each figure that is to be written down is marked with an accent; each ten that is to be dwelt on for a moment is in italics:—

27649	8, 17, 22, 30, 36,	*forty*-five′
9276	10, 19, 20, 27,	*thirty*-one′
808	11, 18, 24, 27, 29,	*thirty*-five′
44615	8, 5, 9, 18,	*twenty*-five′
2799	8, 7,	nine′
10868		
95515		

Let the method of verification be simply taking the columns in the opposite order, or downwards, as 9, 15, 23, 28, 37, *forty*-five′, &c.

Subtraction.—Let the several subtractions be made by mental recovery of additions as in exercise 2: not "7 from 16 leaves 9," but "7 and 9," not repeating 16, which is unnecessary, inasmuch as when 9 is found, 16 is done with, and the carriage of one is all that is to be remembered. The following detail has every word of the process:—

274631807	8 and 9′; 5 and 5′; 10 and 8′; 9 and 2′; 2 and 1′;
95318948	3 and 3′; 5 and 9′; 10 and 7′; 1 and 1′.
179312859	

According to even recent books the computer should say, "8 from 7 I cannot, but 8 from 17 and there remains 9, set down 9 and carry one," &c. It would be shorter than this to say, "8 from the next higher number that ends with 7 leaves 9." Our plan is the abbreviation of "8 and 9 make up the next number that ends with 7" repeating only the first three words.

Multiplication.—Apply the exercises 4 and 5 to the usual process. Here, as before, the detail given has every word which need be repeated. The figures to be written down are accented; all others are carried.

7296	54′, 86′, 26′, 6′5′; 30′, 48′, 14′, 3′6′; 48′, 76,′ 23′, 5′8 ;
859	4′; 6′; 8, 16, 22′; 8, 12, 17′; 4, 10, 16′; 9, 12′; ′6.

6267264	

The usual process of *casting out the nines*, as it is called, though not an absolute verification, is a useful one. Without entering upon its demonstration, we describe it.

Casting out the nines, means adding together the digits of a number and throwing out 9 as fast as it arises. Thus in 26647895 we have—2 and 6 are 8 and 6 are 14, throw out 9 and 5 remains; take in the next figure 4, giving 9, throw out 9 and 0 remains; then 7 and 8 are 15, throw out 9 and 6 remains; pass over the 9 and take in 5 which gives 11, on which two remains. All that is necessary to be repeated is 2, 8, 14, 5, 9, 7, 15, 6, 11, 2. Cast the nines out of both factors, multiply the results, and cast out nines; the answer should give the same figure as the reputed product gives when the nines are cast out. Thus 7296 and 859 give 6 and 4, the product of which is 24, giving 6: and the reputed product 6267264 also gives 6. This is a high presumption that the result is correct: the error, if any, lies in this, that the figures of 6267264 which are too great are exactly compensated by others which are too small. Now it is very unlikely that this exact compensation of errors should exist; and in this unlikelihood consists the strong presumption of verification which the rule of casting out the nines affords.

It may be observed that this rule applies to all operations, thus:—Do with the result of casting out the nines the same as was done with the numbers from which the nines were cast out; the answer, with its nines cast out, should give the same result as arises from casting out the nines of the reputed answer. Thus in the previous example of addition, the nines cast out from the several numbers to be added give 1, 6, 2, 2, 0, 5, the sum of which, with nines cast out, is 7, the same as from the reputed answer 95515. In subtraction, it may be necessary to *take in* a nine before subtracting.

Division.—This rule is considerably shortened, and (in our opinion, though we think many would differ from us) increased in safety, by performing each subtraction without setting down the multiplication. As a preliminary, suppose it required to subtract 7 times 29398 from 410843. Beginning with 7 × 8 instead of putting it down as 56, look at 3 and pass from 56 to 63, writing down the 7 and carrying the 6 tens just used. Take these 6 tens and 7 times 9, giving 69, and make them up to 74, putting down the 5, and carrying 7. All that need be repeated is as follows, dwelling on the tens carried:—

From 410843	56 and 7′ make 63; 69 and 5′ make 74;
Take 29398 × 7	28 and 0′ make 28; 65 and 5′ make 70;
205057	21 and 0′ make 21; 2 and 2′ make 4.

Suppose 3293614829 is to be divided by 47698. Instead of the usual plan, write the divisor on the left, or the quotient on the right: at any rate, the divisor and the quotient should be near one another.

Divisor 47698)3293614829
Quotient 69051 431734
245282
67929
20231 remainder.

The work is as follows:—The first quotient figure being 6, subtract 6 times 47698 from 329361, thus: 48 and 3′ are 51, 59 and 7′ are 66, 42 and 1′ are 43, 46 and 3′ are 49, 28 and 4′ are 32. The 4 being brought down, and 9 ascertained to be the next quotient figure, we have 72 and 2′ are 74, 88 and 5′ are 93, 63 and 4′ are 67, 69 and 2′ are 71, 43 and 0 (unnecessary) are 43. Then 8 and 2 are brought down, 0 and 5 written as quotient figures, and 40 and 2′ are 42, 49 and 9′ are 58, 35 and 7′ are 42, 39 and 6′ are 45, 24 and 0 are 24. The last quotient figure is 1, and 8 and 1 are 9, 9 and 3′ are 12; 7 and 2′ are 9, 7 and 0′ are 7, 4 and 2′ are 6.

Casting out the nines, the products obtained from the divisor and quotient, increased by the result of the remainder, ought, after casting out nines, to agree with the dividend. Here the divisor gives 7, the quotient 3, and the remainder 8: 7 times 3 and 8 is 29, giving 2; the dividend also gives 2.

We have put down every step of the work in all the rules. The very basis of this method is the acquisition of such expertness in the previous exercises as will enable the computer to dispense with a large quantity of the ordinary halting-places. We need not enter upon the rules for the extraction of the square and cube root [SQUARE], or of the solution of equations [INVOLUTION AND EVOLUTION], at length; but we shall annex an example of each, leaving the reader to apply the seventh exercise in its proper place. In the contracted part of Horner's method, we add to the method of the last article cited, a provision for making the first figure on the right of the vertical line of contraction as correct as the process will allow it to be. This last process (Horner's method) is the best exercise of computation. It involves all rules in a form of considerable detail and dispersion.

First, we put down the process for the extraction of the square root of 157.

In both these examples the result is carried to about three times as many figures as are usually wanted. But this is what should be done in computing for exercise. No one does his very highest with ease or with certainty; and a person who can safely and rapidly knock off the seven or eight figures which are generally requisite must be one to whom a much larger amount of correctness is, or has been, familiar.

It is necessary to insist particularly upon acquiring the habit of rapid computation by attempts at rapidity. Taking any exercises which verify one another, as a multiplication and a division, or a raising of a square and extraction of the square root, the learner who has acquired a little familiarity with the rules should try them at the top of his speed. If the verification be attained; if the division, for instance, reproduce the multiplier for a quotient, without remainder, it is thousands to one that the whole process is correct. But if there should be a failure, as may, and almost certainly will at first, happen several times running, there is no occasion to examine closely into the reason of the failure. The whole question should be thrown aside, and another should be taken. In this course it will soon appear that the attempts become more and more nearly correct, until at last failure is the exception, and not the rule. There must be no fear of error, whether there be cause for it or not. The young calculator should proceed as boldly as if he were infallible; for he may depend upon it, that it is not inaccuracy which is to be avoided by precaution, but accuracy which is to be obtained by habit.

With regard to minor points, every one must decide for himself whether actual vocal repetition of the words and numerals necessary to the process does or does not tend to accurate working. Some persons cannot compute without repeating to themselves; but it is worth while to give silence a fair trial. It would also be of assistance to some persons to invent a habit of signifying the multiplier, which is in actual use, by some arbitrary position of the left hand. Thus, 1, 2, 3, and 4 might be signified by placing the corresponding number of fingers of the left hand on the paper, 5 by placing the thumb only, and 6, 7, 8, and 9 by the thumb, with a corresponding number of fingers.

In all those parts of computation which relate peculiarly to fractions, common or decimal, we know of no guide but reason. The ultimate process, the actual step for the time being, must be either addition, subtraction, multiplication, or division; and accuracy may be acquired mechanically. However desirable it may be that the learner should demonstrate these processes, his power of performing them does not depend upon his being able to do so. It is otherwise with regard to the new and distinct processes introduced in questions which require fractions; and which are in fact, not themselves processes, but directions for selection of processes.

The general run of commercial calculations hardly needs any distinct preliminary exercise. There is one great improvement of which ordinary methods are susceptible, namely, the expression of the parts of a pound decimally, instead of by shillings, pence, and farthings. Until a decimal coinage is obtained [STANDARD], any person with a moderate knowledge of decimal fractions may procure for himself most of its advantages, by the rules which are given in INTEREST, together with what we here subjoin. The demonstration will be easy enough to those who consider the fraction which one farthing is of a pound, ·00104166666 . . . . , or ·00104⅙.

To write down any fraction of a pound decimally, proceed as follows :—

Fill up the *first place* of decimals with 1 for every pair of shillings; and the *second and third places* with 50 for the odd shilling, if any, and 1 for every farthing in the pence and farthings, with an additional 1 if these amount to sixpence. Thus, as far as three places of decimals, 8*s*. is ·4*l*., and 9*s*. is ·450*l*.; 9*s*. 3*d*. is ·462*l*., 9*s*. 5½*d*. is ·472*l*., 9*s*. 6*d*. is ·475*l*., 9*s*. 8¾*d*. is ·486*l*.

Fill up the *fourth and fifth places* with 4 for every farthing above the last sixpence, and an additional 1 for every three halfpence. Thus, as far as five places of decimals, 9*s*. 3*d*. is ·46250*l*., 9*s*. 5½*d*. is ·47291*l*., 9*s*. 8¾*d*. is ·48645*l*., 9*s*. 10¼*d*. is ·49270*l*.

Fill up *all the remaining places* with the decimal fraction derived from the number of farthings above the last three halfpence for a numerator, and 6 for a denominator. Thus, 9*s*. 3*d*. is completely expressed in ·4625*l*., 9*s*. 5½*d*. is ·472916666 . . . *l*., 9*s*. 8¾*d*. is ·4864583333 . . . *l*., 9*s*. 10¼*d*. is ·492708333 . . . *l*., 10*s*. 0¾*d*. is ·503125*l*., 3*s*. 3½*d*. is ·164583333 . . . *l*.

For the most part three places are sufficient; and it is rarely that more than five are wanted. The inverse rule, namely, that for reading off a fraction of a pound into shillings, pence, and farthings, is done from the first three places, within a farthing, by allowing a pair of shillings for each unit in the first place, another shilling for 50 (if there be so much) in the second and third places, and a farthing for each 1 that is left in the second and third places, deducting 1 if 25 or more be left. Thus ·12345*l*. is 2*s*. 5¾*d*., ·29933*l*. is 5*s*. 12*d*.* or 6*s*., ·267*l*. is 5*s*. 4¼*d*.

These rules look repulsive at first. None but those who have practised them until the transformation is easily made, can have any idea of the amount of labour which they save. They are in fact as good as a decimal coinage to those who have mastered them. Those who doubt of it may try the following question in the usual way, and compare it with the decimal mode.

When the government, for ease of calculation, proposed seven pence in the pound instead of 3 per cent., as an income tax, how much tax, to a farthing, did they give up on 100 millions of income? On one pound 3 per cent. is ·03, and seven pence is ·0291666666 . . . . , which falls short of the former by ·0008333333 . . . : and this, taken 100 million of times, is 83333·333*l*., or 83333*l*. 6*s*. 8*d*.

Some development of the reasons for the plan which forms the main part of this article will be found in the 'Companion to the Almanac' for 1844.

CONCAVE and CONVEX—CONCAVITY and CONVEXITY. A curve or surface is concave on the side on which straight lines drawn from point to point in it fall between the curve or surface and the spectator; that side is convex on which the curve or surface falls between such lines and the spectator. A surface may be either entirely concave, as the inside of a sphere, or entirely convex, as the outside; or concave in some directions and convex in others, as the surface of a dice-box, or that made by the revolution of an hyperbola about its minor axis.

CONCAVE LENSES. [LENS.]

CONCAVE MIRRORS. [MIRROR.]

CONCEALMENT OF BIRTH. [INFANTICIDE.]

CONCENTRIC, having the same centre; thus, concentric circles are those described about the same point.

CONCERT, in music, a performance of several pieces of either vocal or instrumental music, but commonly of both, by different voices, and on various instruments. The earliest concert of which we find any record is that of the *Filarmonici*, at Vicenza, which must have been founded previously to 1565; for in that year another society, the *Incatenati*, was joined to it. But to England is due the credit of having instituted the first regular series of concerts, under the title of *The Academy of Antient Music*, which had its birth in 1710, and continued to exist upwards of eighty years. The *Concert Spirituel* of Paris was indebted for its origin to an elder brother of Philidor, the well-known composer and renowned chess-player, who in 1725 obtained a licence for the performance of sacred music during Lent. This proceeded without interruption till the French Revolution. The year 1776 is distinguished in musical history by the institution of the *Concert of Antient Music*, which became the asylum of classical compositions at a time when fashion threatened their extinction, and has ever since proved a school of music of inestimable value, by keeping alive a taste for the finest productions of the old masters. In 1791, Salomon, the celebrated violinist, commenced a series of subscription concerts at the Hanover Square Rooms, for which he engaged Haydn, not only to write those twelve grand symphonies which are among the glories of the art, but to come to London to conduct their performance. These concerts continued to be given until 1796, when they ceased; and with them seemed to die away all relish for grand instrumental compositions. But in 1813, a party of eminent professors, with a view to rescue orchestral music of the highest class from the neglect into which it had fallen, formed themselves into a body under the title of the *Philharmonic Society*, and during that season they gave eight subscription concerts, the success of which, both as regards the main design and the support they received, was without any parallel. They constitute an era in the art, and by their continuance act powerfully in promoting the advance of music.

Our space will only allow us to name some few other concerts which have risen up in the British metropolis, flourished for a time, then fallen to decay. Bach (John Christian) and Abel, in 1763, established subscription concerts, which flourished for twenty years. These were succeeded by *The Professional Concert*, which, after a struggle, yielded to the enterprise and ability of Salomon. The *Vocal Concerts* of Harrison and Knyvett began in 1792 at Willis's Rooms, and were discontinued at the end of the season of 1794. They were revived in 1801 by Messrs. Bartleman, Harrison, Knyvett, and Greatorex, and were conducted on a much larger scale. Their success at first was great, but they gradually fell off, and in 1821 were finally abandoned. In 1808, and two following years, Mrs. Billington, Mr. Braham, and Signor Naldi had subscription concerts at Willis's Rooms, and were opposed by Madame Catalani at the Hanover Square Rooms. In 1828, a weak and futile attempt was made to establish *British Concerts*, for the performance of music by native composers. For the same purpose a society was founded in 1834, under the name of the *Society of British Musicians*, but it has entirely failed in accomplishing its object. In 1833, a *Vocal Society* of thirty professional members sprang up at the Hanover Square Rooms, and gave six concerts, consisting almost entirely of vocal music, ancient and modern, of every school. They were conducted on a principle so laudable that every lover of the art felt an interest in their success.

Among the more permanent concerts are those given by the pupils of the Royal Academy of Music, at the Hanover Square concert rooms, to which the public are admitted. Exeter Hall, Strand, is much used for performances of various kinds of music, chiefly sacred. The *Sacred Harmonic* society, established in 1832, holds its meetings in this hall, as does also the *London Sacred Harmonic* society, an offshoot of the former. The oldest society in London for the practice and performance of sacred music is the *Cecilian* society, established in 1785. There is also the *Choral* society, established in 1791. The *Royal Society of Musicians* was established in 1738, Handel being one of its earliest members and benefactors. It was incorporated in 1790, and its object is to relieve decayed musicians, their widows and orphans, which it does by means of a fund raised at various times by donations and bequests, and also by the proceeds of concerts and an annual festival given by the society. In 1839, the *Society of Female Musicians* was established for the relief of its decayed members, and the first concert for the benefit of the charity was given in June, 1840. We may also mention the *Madrigal Society* (1741), which has an annual festival in January in the Freemasons' Hall, with monthly meetings during the season for the performance of madrigals, motetts, &c. There is also the *Western Madrigal Society* (1840); the *Nobleman and Gentleman's Catch Club* (1761); the *Glee Club* (1787); the *Melodists' Club* (1825); the *Purcell Club* (1837); the *Round, Catch, and Canon Club* (1843); the *Abbey Glee Club*, founded in 1841, by some gentlemen who had received their musical education in the choir of Westminster Abbey; the *Adelphi Glee Club*, so named from having been founded in 1833 by two brothers. There is also the *Choral Harmonists' Society* (1834); the *Amateur Musical Society* (1846); the *Musical Union* (1845). Concerts are also given at the Crystal Palace, St. Martin's Hall, St. James's Hall, and other places in the metropolis; while there is scarcely a town in the kingdom that has not its musical societies, which occasionally give concerts. Birmingham, Liverpool, Bradford, Leeds, and Manchester, have their music halls, their organs, their resident performers, and choruses. Even so remote a town as Aberdeen has a new hall, an organ, and 500 chorus-singers. This success is in great measure due to the foreign method of training singers in large masses which was introduced into this country about twenty years ago, under government patronage, and ably carried out by Mr. John Hullah. In this method, not only is a rudimental musical education given, but vocal part music is taught in large classes. Teachers of the method have been scattered all over the land, so that, aided by the publication of cheap music, a wide-spread taste for good music has been diffused among the working-classes, and the teaching of music is permanently established in charity schools.

---

* When 49 is left in the second and third places, this mode gives the same as when 50 is left. The direct rule gives the exact truth or a little less, the inverse rule gives the exact truth or a little more; about one farthing more in the case here before us.

CONCERT PITCH, in Music, is the *pitch*—the degree of acuteness or gravity—generally adopted for some one given note, and by which every other note is of course, governed. *Concert-pitch* has frequently much varied, and musicians have hitherto (with one exception) made little if any effort to obtain a fixed standard, though so desirable, and so easily established. Many years ago, Fischer, of Berlin, ascertained that the number of vibrations per second in the pitch note A, in four celebrated Continental orchestras was as follows; *Berlin Theatre*, 437-$\frac{32}{100}$, the *Grand Opéra Français* at Paris 431-$\frac{34}{100}$, *Opéra Comique*, 427-$\frac{61}{100}$, and *Opera Italien*, 424-$\frac{17}{100}$, which would give for the pitch note C adopted in this country, 524-$\frac{78}{100}$, 517-$\frac{61}{100}$, 513-$\frac{18}{100}$, and 509 vibrations per second respectively. The Philharmonic C used in this country, is equal to about 500 vibrations per second. Some years ago, when Mr. Hullah introduced the Wilhelm method into this country under the patronage of government, he applied to Mr. Charles Tomlinson to adjust a standard tuning-fork, for the regulation of his classes. It was recommended that the natural C represented by 512 vibrations per second be adopted as the standard, that number being preferred from its being the power of 2, and, moreover a good mean between the 524 vibrations of Berlin, and the 500 of the Philharmonic Society. This recommendation was adopted, and during the last eighteen years many thousand tuning forks have been issued, all of which have passed through Mr. Tomlinson's hands. Hence it may be safely asserted that a uniformity of pitch has been attained throughout the country in the numerous classes taught on Mr. Hullah's method, such as has never before been approached or attempted. At the time we are writing, the Society of Arts, London, apparently quite unaware of what Mr. Hullah had been practising for eighteen years, have formed a committee of distinguished individuals, to consider the whole subject of concert pitch and to report thereon. The result of their deliberations, if any, will be given under the article TUNING.

CONCERTI'NA, a musical instrument invented by Professor Wheatstone, the principle of which is explained under ACCORDION. The concertina, in its simple form, claims priority of the accordion in point of date, though the former, in its highly improved state, and as now generally in use, was more lately introduced.

This instrument is composed of a bellows, with two hexagonal faces or ends, and on these are placed the various stops or studs, by the action of which air is admitted to the laminæ (or tongues, or steel bars) producing the sounds; and hereon are also fixed the thumb-straps and finger-rests. The finger-stops are in four rows, the two middle ones confined to the notes of the natural scale, the two external rows to the flats and sharps. Each sharp and flat is placed by the side of its corresponding natural note, and the instrument has, in addition to a complete chromatic scale, two other notes in each octave, whereby the chords in different keys are rendered more perfect than on the organ or piano-forte, and by which also the fingering of the various scales is rendered equally easy.

The concertina, when the bellows is extended, is twelve inches in length, and the sides are about six inches wide. Its compass is three octaves and three notes, commencing at G, the fourth space in the base, and thence ascending. Some instruments, however, are made with a higher, some a lower, scale. That which we here describe is called the *double-action concertina*, because two springs, or tongues, are given to each note, in order that the same sound may be produced, whether the bellows be pressed in or drawn out. The *single-action concertina* has but one spring, or tongue for each note, and it yields a sound only when the bellows is moved inwards; that is, pressed. But it is provided with a self-acting valve, in order that the bellows may collapse instantaneously, which closes while the latter is pressed, and opens to admit air when it is expanded.

There are also tenor and base concertinas: the compass of the first from C, the second space in the base, to C the second additional line above the treble: of the last, from the second additional line below the base, to the third space in the treble. [HARMONIUM.]

CONCERTO, in Music (an Italian word adopted in our language), a composition in which many performers play in concert, that is, in unison, but in which some one or two instruments take rather a more prominent part than the others. Such are the concertos of Corelli, Handel, Geminiani, Avison, &c. But from the latter part of last century the term has been applied to the species of composition written for one principal instrument, with accompaniments for a full orchestra. Of this description are the piano-forte concertos of Mozart, Dussek, Cramer, Beethoven, &c.; and the violin concertos of Viotti, Rode, &c. It must be observed, however, that in the concertos of Mozart and Beethoven the orchestral parts are so full and so essential, that those compositions may, if the expression is allowable, be designated as symphonies with a piano-forte part *obbligato*.

CONCHIOLIN. An azotised organic substance little examined, found in some species of shells.

CONCHOID (κογχοειδής, resembling a shell). This name was given by Nicomedes (in the 2nd century) to a curve, by which he proposed the finding of two mean proportionals, and the duplication of the cube. It is found in the commentary of Eutocius on the sphere and cylinder of Archimedes, and in the fourth book of Pappus.

This curve is described by a revolving line, which passes through a fixed point, and is always produced to meet a certain fixed line. On the revolving line, from the point at which it meets the fixed line, set off a given line both ways. The two points thus laid down trace out the upper and lower conchoid, two branches of the same curve. The lower conchoid has two points of contrary flexure, a cusp, or a loop, according as the given line is less than, equal to, or greater than the perpendicular from the pivot of revolution to the fixed line. Taking the pivot of revolution as the origin, and the perpendicular just named as the axis of x, the equation of the conchoid is,

$$(x^2 + y)(x - b)^2 = a^2 x^2,$$

where a is the given line, and b the distance of the pivot from the fixed line.

CONCINNOUS INTERVALS, in Music, are the various concords. [CONCORD.]

CONCLAVE (a Latin word, which signifies a private room) is the name given to the assembly of cardinals when they meet for the purpose of electing a pope. [CARDINAL.] The day following the last of the funeral of the late pope, the cardinals, after hearing a solemn mass de Spiritu Sancto, proceed to one of the pontifical palaces, generally the Vatican, where rooms have been prepared for each of them, and where they remain shut up till the election has taken place. The keys of the palace are left in the care of a prelate, chosen previously by the cardinals, and who is styled governor of the conclave. Each cardinal has with him a secretary, called conclavista, and two domestics. They meet once a day in the chapel of the palace, where a scrutiny is made of their votes, which are written and placed in an urn: this is repeated every day till two-thirds at least of the votes are in favour of one candidate for the pontifical chair, who is then considered as duly elected. Each cardinal in giving his written vote accompanies it by his name, written in a separate sealed paper, which is not opened till the pope is elected, when the names of the voters are made known. When the election is strongly contested, and the cardinals grow weary of being shut up in conclave, negotiations in writing are carried on between the leaders, and a compromise is entered into by which two or more parties, not being able singly to carry the election of their respective candidates, join in favour of a third person, who is acceptable to them all, or at least not obnoxious to any of them. This often gives an unexpected turn to the election. During the conclave the ambassadors of Austria, France, and Spain, have a right to put their veto each upon one particular cardinal, whose election would not be acceptable to their respective courts. The new pope being elected, and his assent being given, he proceeds to dress himself in his pontifical robes; after which he gives his blessing to the cardinals, who give him the osculum pacis (kiss of peace). After this the name of the new pontiff is proclaimed to the people, from the great balcony of the palace, and the castle Sant' Angelo fires a salute, and all the bells of the city of Rome ring a merry peal for one hour. (Calindri, 'Saggio Geografico Statistico dello Stato Pontificio,' 1832.)

Regulations for the conclave, and the mode of election, have been issued by several popes, beginning from Nicholas II., in the council of Lateran, in 1059, down to Gregory XV., by his bull of 1621, and Urban VIII. in 1625. In times of war or civil disturbance the conclave has been held in other places besides Rome; that in which Pius VII. was elected was held at Venice. Accounts of particular conclaves have been given by numerous writers who have treated of the history of the popes. (Meuschen, 'Cæremoniale Electionis et Coronationis Pontificum Romanorum,' Frankfort, 1732.)

CONCORD, in Music, two combined sounds which are universally agreeable to the ear. It is commonly held, that the more frequently the vibrations of two strings coincide, and—which amounts to the same thing—the lower the terms in which the proportions of vibrations are expressed, the more pleasing the concord; but the 4th, an interval much less agreeable than either the 3rd or 6th, is a formidable exception to those rules, proving their fallibility by the test of experience. Rousseau is of opinion—and we agree with him—that the pleasure afforded by concords is attributable to their source, namely, the perfect chord [CHORD], which is itself the product, or combination, of nature. This, and its inversions, furnish us with all the concords.

Concords are the 8th (or octave), 5th, 3rd, and 6th. Their ratios are, 2 : 1, 3 : 2, 5 : 4, 5 : 3. The two first are called *perfect*, because, as concords, not liable to any alteration by sharps or flats. The two last are called *imperfect*, because alterable.

The 4th has always proved a stumbling-block to writers on harmony, for the reason above alluded to; but as a component part of an inversion of the perfect chord, it has some claim to be admitted among the concords. A great and recognised authority of the modern French school, says, that it is treated as a discord in relation to the bass, as a concord in relation to the middle and upper parts. M. Catel, however, has not in this instance proved as correct as usual: except in the chords of $^{4}_{3}$ and $^{6}_{4}$, the 4th, as an inner part, is, and can only be, treated as a discord.

CONCORDANCE, "a book which shows in how many texts of Scripture any word occurs." (Dr. Johnson). More particularly, it is a dictionary or index of all the important words in the Bible, alphabetically arranged for the purpose of finding passages and of comparing the various significations of words. To critical interpreters this class of books is justly considered of the greatest utility, as furnishing an instrument by which the determination of the meaning of obscure expressions may be greatly facilitated by reference to all the parallel passages. "A good concordance," says Dr. Geddes ('Prospectus,' p. 71), "is undoubtedly the best means of understanding the Hebrew Scriptures." While the Bible remained in manuscript, and was not divided into chapters and verses, indices of the words and phrases could neither be formed nor used; but as soon as these divisions began to be made, the great importance of concordances, or alphabetical indices, was at once perceived, and several learned men employed much time and labour in constructing them. The compiler of the first concordance in any language was Hugo de St. Caro, or Cardinal Hugo, who died in 1262. The earliest concordance of the Hebrew text is by Rabbi Mordecai Nathan, printed at Venice in 1523. Its Hebrew title is, 'The Light of the Way.' It contains all the Hebrew roots, branched into their various significations, and is said to be the produce of ten years of incessant labour. A more correct edition was published at Basil in 1581, and a Latin translation by Reuchlin in 1556; but both the Latin and the Hebrew editions are extremely inaccurate. The errors are, for the most part, corrected in the work by Calasius, which combines the labours of Nathan and Reuchlin. It is entitled 'Concordantiæ Sacr. Bibliorum Hebr. et Lat.,' 4 tom. fol. 1621. The additions by Calasius consist of very learned and laborious etymological remarks. The reprint of this ponderous work in London in 1747-9 contains among its subscribers all the crowned heads of Europe, including the Pope. The work by the elder Buxtorf, 'Concordantiæ Bibliorum Ebraicæ nova et artificiosa methodo dispositæ,' &c., fol. 1632, is more correct than Nathan's; but the references are made by Hebrew letters, and to the Rabbinical divisions of the Old Testament. An abridgment of it, by Ravius, is entitled, 'Fons Zionis, sive Concordantiæ Hebr et Chald.,' 8vo. 1677. Dr. John Taylor, under the patronage of the English and Irish bishops, published, in 2 vols. fol. 1754, 'A Hebrew Concordance, after the manner of Buxtorf, adapted to the English Bible.' It is a complete and useful book for the English scholar. The 'Concordantiæ Particularum Ebræo-Chaldaicarum,' fol. 1675, and 4to, 1679, by Noldius, Theological Professor at Copenhagen, is very valuable for the explication of passages dependent on the Hebrew particles, a comparison of which is made with the Greek. The best edition is that of Jena, in 4to, 1734, with a Lexicon of Particles, by Michaelis, extremely useful to the Hebrew critic. There is also the 'Concordantiæ Librorum Veteris Testamenti Hebraicæ atque Chaldaicæ' of J. Fuerstio, fol., Lips. 1840.

With respect to concordances of the Greek Septuagint, we may notice especially, Kircheri 'Concord. Vet. Test. Græcæ, Ebræis vocibus respondentes,' 2 tom. 4to, 1607; but the Hebrew being placed first, it is more useful for consulting the Hebrew than the Greek text. The most complete and accurate work of this description is Trommii 'Concord. Græcis Versionis dictæ LXX,' 2 tom. fol. 1718. "I wish," says Michaelis, "this Concordance were in the hands of every theologian." It contains Heb. et Chald. Indices; but the book of Daniel is omitted, the Septuagint version of it being at that time unknown.

The most important concordances of the Greek New Testament are, Betuleii 'Concord. Græcæ Nov. Test.,' fol. 1546. This is the first which appeared: it is now extremely scarce. 'Concord. Græco-Latinæ Nov. Test. ab Hen. Stephano Concinnatæ,' fol. 1594, 2nd ed. 1624, is a work unworthy of so distinguished a man, on account of its great inaccuracy. Schmidii 'Nov. Test. Græci ταμιεῖον,' fol. 1638, revised ed. 1717 at Gotha, was beautifully reprinted in 2 vols. 8vo, at Glasgow, 1819. It is much more correct and valuable than that by Stephens. The 'Lexicon Anglo-Græco-Lat. Nov. Test.,' by Andrew Symson, fol. 1658, is a work of prodigious labour, but rendered almost useless by its bad arrangement. The 'Concordance to the Greek New Testament,' with the English to each word, by Dr. Williams, 4to, 1767, is sufficiently complete for ordinary purposes. A very valuable work is C. H. Bruder's 'Omnium Vacum Novi Testamenti Græci,' 4to, Lips. 1843. The first concordance to the Latin Vulgate is that by Cardinal Hugo, entitled, 'Concord. Bibliorum et Canonum,' fol. 1479. After the revision of the Vulgate by Pope Sixtus V., a new and amended edition of Hugo's work appeared at Antwerp in 1617, and subsequently at Geneva in 1625, and at Paris in 1683. There have since been a great number of reprints. The best is that of Avignon, 2 vols fol. 1786. In compiling the original MS. it is said that the cardinal engaged the services of 500 Dominican monks.

The first Concordance to the English New Testament was "imprinted by Thomas Gybson" previous to the year 1540. The first to the entire Bible is by "Jhon Marbeck," London, in folio, 1550. Subsequent to these there have been several, the principal of which are, Knight's 'Concordance Axiomatical,' fol. 1610; Cotton's Concordance, fol. 1618; Newman's large and complete Concordance, fol. 1643; Bernard's 'Thesaurus Biblicus,' fol. 1644; Wilkins's Concordance, 4to. 1647; Powell's, 8vo. 1671; the 'Cambridge Concordance,' fol. 1689; Butterworth's, 8vo, 1767. But by far the most complete and valuable is the one by Alexander Cruden, the merits of which are too well known to require any remark. The first edition was in 4to, 1737; but the most correct is that of 1810. An 8vo. edition, beautifully printed, appeared in 1824. We must notice finally the 'Concordance of Parallels,' by the Rev C. Crutwell, 4to, 1790. It is a work of great value, compiled with immense labour from a multitude of Bibles and Commentaries in the Hebrew, Latin, French, Spanish, and other languages. For further details respecting the Concordances here mentioned, and several others, see Watt's 'Bibliotheca Britannica;' Orme's 'Bibliotheca Biblica,' and Darling's 'Cyclopædia Bibliographica.'

The word has come to be used in a similar sense as applied to other works. Twiss and Ayscough each published a Concordance to Shakspere, but they have been completely superseded by the excellent one compiled by Mrs. M. Cowden Clarke in 1847.

CONCORDAT is the name given to a formal agreement between the see of Rome and any foreign government, by which the ecclesiastical discipline of the Roman Catholic clergy and the management of the churches and benefices within the territory of that government are regulated. It is, in fact, a diplomatic negotiation and treaty concerning ecclesiastical affairs, including also temporalities belonging to the Church. The frequent disputes between the popes and the various states of Europe touching the right of appointing to vacant sees and benefices [BENEFICES], and also about the claims of the see of Rome to part, or in some cases the whole, of the revenues of vacant sees and livings, and of the first fruits and tenths of those which it had filled, as well as the immunities claimed in various times and countries by the clergy and supported by Rome, such as exemption from taxation, and from the jurisdiction of the secular courts, the right of asylum for criminals in the churches, and other similar claims, the particulars of which are found in the history of every country in Europe;—all these have given occasion to concordats between the popes and particular states, in order to define the rights of each party, to draw a line between the secular and ecclesiastical jurisdictions, and thus put an end to controversy and scandal. By the concordat of 1516 between Leo X. and Francis I., the king abolished the right exercised by the chapters of electing the respective bishops, a right assured to them by St. Louis and by the states of the kingdom under Charles VII. in 1438. The parliament refused for two years to register this concordat, as contrary to the spirit of the general councils and the liberties of the Gallican Church; it registered it at last, March 19, 1518, "by express and repeated commands of the king." (Gregoire, 'Essai Historique sur les Libertés de l'Eglise Gallicane.') Concordats became most frequent from about the middle of the 18th century, an epoch from which the European governments have made themselves more independent of the ecclesiastical power, and the popes have been for the most part men of an enlightened and conciliatory spirit. Benedict XIV., by a concordat with the King of Sardinia, in 1741, gave up to the latter the right of nomination to benefices in various provinces of the Sardinian monarchy, which the see of Rome had claimed till then, as well as the temporalities of the same during a vacancy. A concordat was made between the pope and Charles, king of Naples, about the same time, by which the property of the clergy became subject to taxation, and the episcopal jurisdiction in temporal matters was greatly limited. By another concordat between Clement XIV. and the King of Sardinia, the right of asylum to criminals in the churches was much restricted, and full power was given to the respective bishops to expel and give up to the secular power those guilty of heinous offences. But the most celebrated concordat is that agreed upon between Cardinal Consalvi, in the name of Pius VII., and the first consul Bonaparte, in July, 1801. By it the head of the state had the nomination to the vacant sees, but the pope was to confer canonical institution, and the bishops had the appointment to the parishes and their respective dioceses, subject however to the approbation of the government. The clergy became subject in temporal matters to the civil power, just like laymen. All immunities, ecclesiastical courts, and jurisdictions were abolished; and even the regulations of the public worship and religious ceremonies, and the pastoral addresses of the clergy, were placed under the control of the secular authorities. Most of these provisions remain in force in France to the present day. Other concordats have been made with some of the Italian states. By that of 1818 with Naples, the king proposes the bishops, subject to the pope's scrutiny, and the pope consecrates them; the bishops have the right of censorship over the press; and the ecclesiastical courts are re-established for matters of discipline and for ecclesiastical causes as defined by the council of Trent. Appeals to Rome are allowed. It appears from the above facts, that the ecclesiastical authority and influence in Roman Catholic countries vary considerably according to the concordats, if there be any, entered into with Rome, or according to the civil regulations adopted and enforced by the respective governments towards the clergy as towards laymen. The most recent concordat is that with Austria in 1855, by which the papal power was widely extended over all the Austrian dominions, and a large amount of jurisdiction was granted to it over all institutions for purposes of education, and over works issued from the press. In Sept. 1859, however, an imperial patent relieved the Protestants, both Lutheran and Calvinistic, of Hungary, Croatia, Servia, and Transylvania, from all subjection to Roman Catholic authorities, and provided for the ecclesiastical and educational regulation of their communities by consistories of their own choosing.

CONCRETE, *concrétum*, in philology and metaphysics, is an epithet applied to the conception or expression of a quality which refers to or implies some particular subject in which the quality exists. It is used to denote a term having a naturally implied union with a subject; in other words, it signifies a quality accompanied with its particular subject, without any mental separation or abstraction, as learned, long, wise, round. It is therefore directly opposed to *abstract*, which denotes a quality conceived generally and separately, without reference to any object to which it belongs, as learning, length, wisdom, roundness. Thus the names of classes are abstract, and the names of individuals concrete; and from concrete adjectives are made abstract substantives. Concrete numbers are subject to the same explanation, being such as indicate or directly imply a subject, as two men, five shillings, in contradistinction to abstract numbers, which denote a conception of the aggregate of two or five units. Concrete terms, in the scholastic phraseology, are called *paronyma*. The following remark is from Locke's 'Essay' (b. 3, c. 8, § 1): "This distinction of names shows us the difference of our ideas; for if we observe them, we shall find that our simple ideas have all abstract as well as concrete names, the one a substantive, the other an adjective, as whiteness, white, sweetness, sweet."

CONCRETE, an artificial conglomerate used by builders, principally in foundation works, when the subsoil is of a damp, or of a compressible nature; it is usually made of lime, sand, and gravel or broken stone, and its useful action in the cases above cited consists in the perfection with which this conglomerate forms a solid, homogeneous mass—a species of monolith, in fact, able to distribute the superincumbent weight over the whole surface it covers. Sometimes concrete is used as a backing to quay or retaining walls, and then its successful application depends on the degree of hardness or solidity it may attain, and to its powers of resistance to the transmission of water. Occasionally, also, concrete is used as a walling material by ramming it into moulds, which have, as matrices, the forms the concrete itself is intended subsequently to represent in relief. According to the purposes the material is thus required to fulfil, it is necessary to adopt more or less care and skill in its fabrication; and indeed, in some cases, the differences in the style of manipulation adopted are so great as almost to render necessary the introduction of the French word *beton*, to express a mode of making concrete which is essentially unlike the one usually adopted in the greater part of England.

The habitual mode of making concrete adopted in the south-east of England, is to mix the *groundstone lime* obtained from the calcination of the chalk marl (a species of argillo-calcareous stone, in which the silicate of alumina is present in proportions varying from 8 to 14 per cent. in the best varieties) with *screened ballast*, or shingle, in the proportion of one of ground-lime to 7 or 9 of ballast, measured in bulk; and to perform the operation of slaking, or of supplying the quantity of water required for the subsequent crystallisation of the lime, simultaneously with the intermixture of the above ingredients. The lime and ballast are then, after being frequently turned over, thrown into the place they are intended to occupy, and in well-executed works they are rammed carefully into all the corners of the foundations. In those parts of England where the more decidedly argillaceous limestones are used for the purpose of obtaining lime, greater precautions are however used, and are required; for that class of materials absorbs water under such very different conditions from the gray-stone lime, that the slaking would not take place satisfactorily, if a longer time and a more intimate contact between the lime and the water, than is admissible in the case of the stone lime, were not allowed in the cases of the use of the blue lias, or of the other limes possessing similar properties to it. The precise nature of these properties will be discussed under Lime; but it is advisable here to state, that the philosophy of the action of that material is, simply, that it should form a binding or cementitious substance, which should in its turn form the *gangue* of the other materials it is intended to connect. This is effected by presenting to the caustic lime (deprived of its water of crystallisation and of its natural dose of carbonic acid by calcination) the quantity of water requisite to enable it again to resume a solid form around any given object; but it is found that the purer varieties of lime do not solidify with sufficient rapidity, or in a sufficiently permanent manner, to allow of their being used in building operations; whilst the varieties which contain certain proportions of clay (silicate of alumina) yield limes which are able to set with rapidity, and even to resist the action of water after a short time. It is on account of this power of resisting the action of water, that some limes are called *hydraulic*, and the others which do not possess it are called *non-hydraulic*; but the hydraulic limes also have these characteristic differences from the non-hydraulic ones, namely, that they absorb the dose of water requisite for their crystallisation very slowly; that they do not sensibly evolve much heat in fixing the water; and that they do not increase much in volume: whereas the non-hydraulic limes absorb water rapidly, and begin at once to decrepitate with a marked increase of volume, and a copious evolution of heat and vapour.

Now, the differences to be observed in the modes of making concrete depend on these respective properties of limes. When the moderately hydraulic limes are used, the operation of slaking takes place so rapidly, that it may often be desirable to hurry the operations connected with its mixture with the materials it is intended to unite; and at any rate there seems to be little danger of a subsequent slaking, when *ground* stone lime is used, and a fair quantity of water is at once presented to it. But in the use of hydraulic limes, this careless mode of treatment would be fatal to the successful result, for with them it is essential that every particle of the lime should take up its dose of water, and that the whole of the mechanical changes in the lime should be completed before the conglomerate itself is placed in its definitive position. It follows, therefore—and herein practice and theory agree—that the more decidedly hydraulic a lime is, the more perfectly must the operation of hydration be performed; and consequently, in all cases where the hydraulic limes are used, it is customary to mix them with the quantity of sand which would be used to make ordinary mortar, under edge-rollers, and then to mix the mortar so prepared with the screened ballast. This process is, in fact, neither more nor less than the execution of rubble masonry with very small materials; and the resulting material is the one to which it appears to be desirable to apply the term *beton*, by way of contradistinction to the more imperfect and less valuable substance called ordinarily *concrete*. The proportions of lime, sand, and ballast to be used in the formation of beton must depend on the quality of the lime; it being always understood, that the more hydraulic a lime is the less sand will it carry, but that, at the same time, this very same quality renders its use more advisable for foundations to be executed in water, or in damp situations.

A very objectionable practice is sometimes adopted by the London builders, when they use concrete in damp situations, of mixing ground stone lime and ballast without slaking the lime at all, and of leaving it to absorb the requisite quantity of water from the ground, or other position in which the concrete is to be placed. Now, in such cases the slaking must take place irregularly and unequally, and the changes of volume thus produced must tend to disintegrate the mass. In fact, whatever be the description of lime used, it is essential that the hydration should be completed before the concrete or beton is put in place.

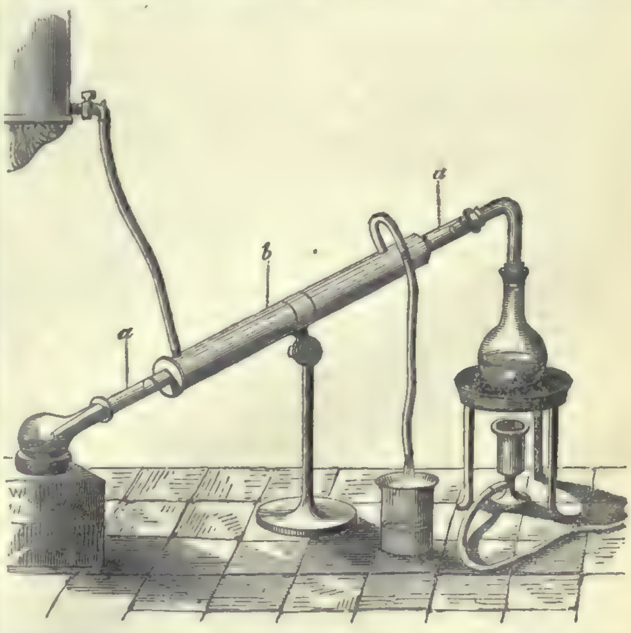
CONCUBINAGE is the cohabitation of a man with a woman, to whom he is not united by marriage. Among the Romans, concubinage was in use before the time of the Emperor Augustus, yet without being formally permitted by law. Augustus, with the view of preventing celibacy and encouraging marriage, A.D. 10, caused the famous law called Lex Julia and Papia Poppæa to be passed, which may be considered as much an ordinance of moral police as a measure in favour of population. This law contained several conditions advantageous for those who had the greatest number of children. By the same law, concubinage was legally allowed to unmarried men, with the restriction that not more than one concubine could be taken, and she must be a woman with whom marriage was not permitted, as women of mean descent, freedwomen, &c. The concubine did not enjoy the same rights as a wife, and the children begotten in concubinage were not considered as legitimate, but were called natural (naturales), a distinction which was of importance as to the right of succession.

Concubinage being inconsistent with the principles of Christianity, the Emperor Constantine the Great enacted laws against the institution, and it is now in all Christian countries considered unlawful. Yet in Germany, among the reigning families, a left-handed or morganatic marriage (Trauung an die linke hand or morganatische ehe) still sometimes occurs. This kind of marriage resembles the Roman concubinage, as well in its conditions as its consequences.

CONCUSSION OF THE BRAIN, SPINE, &c. [Head, Injuries of the.]

CONDENSATION. [Expansion.]

CONDENSER is the name given to any piece of apparatus used for cooling heated vapours, with a view of causing them to assume a liquid condition.



In the ordinary process of distillation, the condenser most commonly employed is the *worm-tub*. This consists of a metal pipe usually twisted into a spiral form, for the sake of compactness, and so fixed in a tub that a few inches of one end of the pipe may pass through, and accurately fit, a hole bored near the bottom of the tub. By this means the metal coil can be kept constantly surrounded with cold water, so that vapours coming from a boiler or other distillatory apparatus are effectually condensed. The upper portions of the *refrigeratory*, as this apparatus is sometimes called, will necessarily become heated first, and as hot water is lighter than cold, an arrangement should be made whereby a stream of cold water can enter at the bottom of the tub and the hot water pass off near the top.

Liebig's condenser is the form most frequently employed in chemical laboratories, and for experimental purposes generally. Its construction, and the method of using it, are seen in the annexed figure.

The glass tube, *a a*, through which the vapours pass, is usually about three-fourths of an inch in diameter, and is surrounded by another tube, *b*, commonly made of tin-plate or zinc, about two inches in diameter, and having at each extremity a neck through which the tube *a* passes. The ends of the necks of the external tube, and a small portion of the glass tube near them, are connected together by means of a strip of sheet caoutchouc carefully bound round. An aperture near the lower part of the external tube admits a current of cold water, and a similar aperture near the top allows the heated water to flow off. The inner tube is thus constantly surrounded with cold water, and heated vapours passing through it are perfectly cooled and condensed.

CONDENSER OF ELECTRICITY. [Electricity.]

CONDIMENTS. [Aromatics.]

CONDITION. Two possible events, A and B, may be so related, that (1) when A becomes event or effect, B also shall become event or effect: (2) or so that B being already event or effect, when A becomes event or effect, B may either cease to be event or effect, or may be diminished as to event or effect, or enlarged as to event or effect. This kind of relationship may be expressed by the term, condition, and the words by which this condition is made, may be any that are free from ambiguity. In case (1) where A must happen before B can, this may be called a condition precedent. In case (2) where B, already being event or effect, is extinguished or modified by the subsequent event A, this may be called a condition subsequent. The events may be more than two, and the condition which expresses their relation may be more or less complicated, but the general nature of the relation will still subsist. The application of this principle to legal questions is simply this: Conditions precedent are conditions annexed to any gift of an estate or interest which at law must be strictly performed, before such estate or interest can vest in the person designated by the gift. Conditions subsequent are when the estate or interest is already vested, but its continuance in the person in whom it is vested depends on the breach or performance of the conditions.

Cases may arise, and in construction of agreements and particularly of wills often do arise, in which it is not easy to say whether the condition is precedent or subsequent; but in general, the difficulty arises rather from certain technical rules of law applicable to the construction of instruments, than from the bare terms in which conditions are expressed.

Littleton's description of an estate upon condition is this: (325) "Estates which men have in lands or tenements upon condition, are of two sorts, viz., either they have estate upon condition in deed, or upon condition in law, &c. Upon condition in deed is, as if a man by deed indented, enfeoffes another in fee simple, reserving to him and his heires yearely a certaine rent payable at one feast, or divers feasts per annum, on condition that if the rent be behind, &c., that it shall be lawful for the feoffor and his heires into the same lands or tenements to enter, &c. And if it happen the rent to be behind by a week after any day of payment of it, or by a moneth after any day of payment of it, or by half a yeare, &c., that then it shall be lawful to the feoffor and his heires to enter, &c. In these cases, if the rent be not paid at such time, or before such time limited and specified within the condition comprised in the indenture, then may the feoffor and his heires enter into such lands and tenements, and them in his former estate have and hold, and the feoffee quite ouste thereof. And it is called an estate upon condition, because that the estate of the feoffee is defeasible if the condition be not performed," &c.

An estate thus given is liable to be defeated, that is, the gift upon non-performance of the condition may be resumed by the giver, or his heirs: this is a condition subsequent, that is, subsequent to the vesting of the estate in the feoffee or grantee.

The following example from Littleton will show the difficulty which has been introduced into the construction of conditions by the peculiar character of the laws of England (Litt. 350): "If land be granted to a man for term of five yeares, upon condition, that if he pay to the grantor within the two first yeares, forty markes, that then he shall have a fee, or otherwise but for term of the five yeares, and livery of seisin is made to him by force of the grant, now he hath a fee-simple conditionall, &c. And if in this case the grantee do not pay to the grantor the fortie markes within the first two yeares, then immediately after the first two yeares past, the fee and the freehold is and shall be adjudged in the grantor, because that the grantor cannot after the said two yeares presently enter upon the grauntee, for that the grauntee hath yet title by three yeares to have and occupie the land by force of the same grant. And so because that the condition of the part of the grantee is broken, and the grantor cannot enter, the law will put the fee and the freehold in the grantor."

On this Coke remarks, that many are of a different opinion from Littleton, because the fee simple is to commence upon a condition precedent (of which class the condition in the case put by Littleton clearly is), and yet "here Littleton, of a condition precedent doth (before the performance thereof) make it subsequent." And yet Littleton is right, for the legal effect of the livery of seisin is to pass a present state of freehold.

It is a rule of law that none but the grantor and his heirs can have the benefit of a condition; and that any conditions are good which are not unlawful, impossible, immoral, or absolutely inconsistent with the nature of the estate given. An instance of the last kind of condition (Littleton, 360) would be a feoffment, or a devise in fee, upon condition that the feoffee or devisee should not alien the land to any person; such a condition, being inconsistent with the estate given, is void.

Before the Statute of Westminster 2, *De Donis Conditionalibus*, if lands were given to a man and the heirs of his body, as soon as he had issue of his body, this fee-simple conditional became for some purposes, and among them, for alienation, an absolute fee-simple. The effect of this statute was to convert conditional fee-simples into estates tail. [Tail, Estates.]

Conditions in English law were of feudal origin. The rents and services of the feudatory were considered as conditions essentially annexed to his fief, and were called conditions in law, or implied conditions. The neglect of these conditions was a forfeiture of the fief to the lord of whom the tenant held his lands. Expressed conditions, or conditions in deed, were subsequently introduced, but as we have already shown, they savoured of their origin in this, that the donor's remedy for breach of conditions was limited to him and his heirs. But the doctrine of conditions has long ago been extended to all such cases as the complicated relations of a rich and populous country require, and, as in the Roman law, so now in the law of England, conditions may form a part of every written instrument by which men regulate their mutual dealings, or dispose of their property. These conditions, and the construction of them, vary with the nature of the instrument of which they form a part; and the construction of such conditions is further subject to some variations, owing to the different aspects under which they are regarded by courts of law and equity.

Those conditions which are of most practical importance, are the conditions of Bonds, Leases, Mortgages, and Wills. The last head includes conditions annexed to portions and Legacies, which have given rise to a great number of disputes, and to numerous and not always consistent judicial decisions.

As to conditional limitations of real property, and the difference between them and remainders and conditions (this being a matter purely technical), the reader is referred to Fearne's 'Essay on Contingent Remainders;' and Butler's note on Co. Litt., note 94.

CONDITION OF A BOND. [Bond.]

CONDITION (Mathematics) is used in nearly the same sense as in common life. Thus the proposition, to describe an equilateral triangle upon a given straight line, is not to describe *any* triangle, but a triangle under the following *conditions*; that it must be equilateral, and that it must have a given line for its base.

An *equation of condition* means an equation which will not always be true, but requires certain conditions to be satisfied; and is distinguished from an *identical equation*, or one which is true independently of all conditions. Thus, $x+x=2x$ and $(a+x)(a-x)=a^2-x^2$ are identical equations: they are true for all values of x and a. But $x+2=3$, and $4x-x^2=3$ are equations of condition: the first cannot be true unless $x=1$, nor the second unless $x=1$, or $x=3$.

But the term *equation of condition* has a more technical meaning in the application of mathematics to the sciences of observation. Suppose, for example, that x, y, and z are certain quantities to be found, but which cannot be observed directly: they are, however, connected with each other by an equation, say $ax+by+cz=h$, where, a, b, c, and h are different at different times, or for different circumstances of observation, but still are so connected that the preceding equation must be true; and where a, b, c, and h can either be observed, or computed from observations. Let a_1, b_1, c_1, and h_1 be the results of a first observation; a_2, b_2, &c., of a second; then for n different observations, we have the n following equations:—

$$a_1x+b_1y+c_1z=h_1$$
$$a_2x+b_2y+c_2z=h_2, \text{ \&c.}$$

If the observations be all correct, any three of these will give the same values of x, y, and z; but if, as must happen, there be errors in every observation, the results of each triad will differ slightly from those of the rest. For the method of solving the whole set, so as to produce the most probable result, see Least Squares, Method of. This is what is called the formation of *equations of condition*.

CONDOTTIERI, a word in the Italian language signifying captains, chiefs, or leaders, but most usually employed to designate soldiers of fortune, who raised corps of cavalry and infantry at their own expense and engaged with princes and governments for their services as mercenaries. The practice of employing these mercenaries, which commenced in the early part of the 14th century, originated in the Italian princes and republics commuting the personal services of their subjects in war for pecuniary payments, with which they were enabled to hire mercenaries. As early as 1225, Genoa took the Count of Savoy into pay with 200 horse. Florence retained 500 French lancers in 1282. After the expedition of the Emperor Henry VII. in 1310, many soldiers of fortune remained in the service of Milan, Florence, and other states. Pisa appears, in 1343, to have disbanded a corps of German mercenaries, whose leader, Guarnieri, refusing to lay down his arms, levied contributions throughout the Italian states. In 1353, a band under the command of Fra Moriale, afterwards of Conrad Lando, called the Great Company, appeared in Italy, and extorted money from many of the Italian states. During the long and bloody wars between our Edward III. and France, foreigners from different parts of Europe, attracted by his fame and liberality, and allured by the hope of plunder, flocked to his standard. They were for the most part men of desperate fortunes, or unable to live at home according to their wishes. At the conclusion of the treaty of Bretigni in 1364, which restored peace to England and France, these soldiers, unable to relinquish a course of life to which they were accustomed, and being without other means of subsistence, were dispersed into the several provinces of France, where they possessed themselves of castles and fortresses, and associating themselves with the banditti of their vicinities, levied contributions on all within their power, and under the names of *companies* or *companions** they became the terror of the peaceable inhabitants of the country. These ruffians formed altogether a body of 40,000 men, and were headed in many instances by some of the most experienced leaders of the time. They fought pitched battles with the troops of France, in which they gained victories. The misery which they occasioned only served to increase their numbers; for poverty and despair drove their victims to their standard. Even their excommunication by the pope produced no abatement in their ferocity and rapine. At length the war between Henry de Transtamare and Peter the Cruel for the succession to the crown of Castile furnished an opportunity to rid France of this scourge. De Guesclin proposed to Charles V., king of France, to enlist these companies into his service and lead them into Castile. They accordingly engaged in this expedition, and in their way forced the pope, then residing at Avignon, to give them a sum of money.

From this time war became a trade in many parts of Europe, particularly in the Italian states, in which needy and desperate adventurers raised forces either by their pecuniary means or by their personal influence and reputation for conduct and courage, and engaged them for hire without the least consideration for the real or supposed justice of the cause in which they embarked. These forces were recruited from the refuse or the vagabonds of every state in Europe. The idle and profligate found in joining their bands a way of life which flattered their indolence and gratified their rapacity. The mode adopted for assembling them was by contracts with nobles who had authority over the loose and disorderly inhabitants of their estates, with captains whose address or bravery could allure adventurers to their banners, or with individuals whose poverty or choice made them offer themselves to princes or governments. In their discipline, though it was far from exact, and in courage and conduct in war, they were superior to the troops which could be then raised under the powers of the feudal system. Besides the profit which they gained on the ransom of their prisoners, their pay, according to the then value of money, appears to have been high (assuming them to have been as well paid as the other troops), and that of the private soldiers to have been at a much higher rate in proportion to the commanders and officers than in modern times. At the siege of Calais, in 1346, Edward, prince of Wales, for himself and retinue, for his wages of war, had 20*s.* a day. The pay of Henry, earl of Lancaster, for his "wages of war," was 6*s.* 8*d.* a day; 11 bannerets, 4*s.* a day; 193 knights, 2*s.*; 512 esquires, 1*s.*; 46 men-at-arms and 612 archers on horseback, each 6*d.* a day. From the known rapacity of these mercenaries, it is not likely that they would have accepted lower terms than the other troops engaged in the same enterprise. According to Villani, they frequently demanded and received double pay, with a premium or bounty-money of a month's pay, on their engagements. But their chief inducement to serve was the plunder of the towns or castles which they took, the contributions they levied, and the ransom of the prisoners. From this motive they were induced not only to spare their own men as much as possible, but to give quarter to their enemies. This rendered some of their battles nearly bloodless, a ludicrous instance of which occurred in one of the Italian wars. Piccinino advanced to attack Florence with an army of several thousand men. The place was defended by Capponi with another body, principally composed of mercenaries. The two armies engaged at Anghiari, a short distance from Florence. The battle lasted four hours. Piccinino was totally defeated, and fled to Borgo San Sepolcro with about a thousand men. The rest were made prisoners; only one man was killed, and this owing to the accident of his falling from his horse and being trodden under foot. Capponi, however, was unable to follow up his success, and his troops refused to advance till they had secured their plunder. Several other battles, equally bloodless, were fought in the wars of this period.

The Condottieri were notorious for bad faith in their engagements with the states they served. Their rapacity was equal to their bad faith; besides their pay, they exacted gratifications for every success. Such was the terror they inspired, that some of the Italian states paid them large sums not to pass through their territories. With the improvement of artillery and the introduction of musquetry the condottieri declined; but it is difficult to state the period of their extinction. Our countryman, Sir John Hawkwood, is said to have been the last, as he was beyond comparison the most eminent for his skill in military affairs. Sir John died at Florence in 1393 at an advanced age, and was buried with great pomp by the Florentines. There is a cenotaph to his memory in the church of Sible Hedingham, Essex, where he was born.

(Froissart; Villani; Machiavelli; Aretin.)

CONDUCTOR OF HEAT. [ELECTRICITY; HEAT.]

CONDUIT, the artificial channel in which water is conducted from the point of supply to the place of delivery or of outfall. It may be either circular or polygonal in section, open or closed, of earth, masonry, or metal, and in each particular case the formation of conduits gives rise to the application of special laws of construction and of calculation. For the purposes of discussion, it would be more convenient to consider the various questions connected with the flow of water in channels of a circular section under the head of WATER PIPES, even when it may not run in them "full bore;" and at present it is therefore proposed to treat solely of channels or conduits with polygonal sections, such as are usually employed in canals, cuts, mill-races, &c.

Practically (that is to say, with reference to the mode of *building* the channels, and assuming that word to apply to the use of all kinds of constructive materials) the system of constructing a channel must be regulated, firstly, by the purposes for which the water it is intended to conduct is subsequently to be applied; and secondly, by local circumstances connected with the choice of materials or the economy of execution. For the purposes of navigation, open channels of a trapezoidal form in earthwork are sufficient, provided the requisite degree of impermeability in the bed be secured; and even for a water supply such channels may be admitted, if the water should flow in the open air of the country, where it would not be exposed to take up atmospheric impurities. But if the earth of which the banks are made should be liable to be removed, or if it be essential to reduce the sectional area of the water-way to the minimum, as when a canal has to be carried upon an aqueduct; or if it be necessary to protect the water from contamination by soot or dust, then the channel must be made of masonry, and, as a general rule, of a rectangular form, though for certain theoretical reasons the portion of the section normally filled would be more satisfactorily made in the shape of a regular half hexagon, whose complete diameter should be the water-line, and be equal to twice the depth.

In earthen channels it is essential to observe that the *bottom* velocity must never exceed that which would be required to remove the materials of which the bed is formed. A certain velocity is at all times necessary in the stream, in order to prevent the growth of the peculiar vegetation which usually grows in earthen channels; but if the velocity should exceed the rates indicated in the following table, the permanence of the channel may be dangerously affected. It is usually considered that the minimum velocity to be given to the waters of any artificial open conduit should be from 10 to 14 inches per second, or from 50 to 60 feet per minute, in order to avoid the dangers of interference with the discharge from the above-named cause; namely, the growth of plants. It is usually considered, however, that the bottom velocities should not exceed the rates of

25	feet per minute	in	soft alluvial beds.
40	„	„	soft clayey beds.
60	„	„	sandy and silty beds.
120	„	„	gravelly beds.
180	„	„	strong gravelly beds.
240	„	„	shingly beds.
300	„	„	shingly and rocky beds.
400	„	„	rocky beds, or in smooth masonry.

In open masonry conduits, wherein the water flows without pressure, the transverse section must depend upon the uses to which the stream is to be devoted; because the draught of canal boats may, for instance, render it necessary to modify the ordinary relations of width and depth; or, in an aqueduct, the effects of ordinary frosts may render it advisable to increase the theoretical depth. In closed conduits the choice of the transverse section will be influenced by the considerations arising from the quality of the waters, and from the precautions necessary to maintain in it a constant flow. As it is usually possible to regulate the admission of the water, it would seem that the form which would most commonly be adopted would be the semicircle, because in a channel of that form the wetted border would be the least in proportion to the volume discharged. But it is found that it is easier to execute a long artificial channel with the requisite degree of regularity of outline and of fall, when its section is made nearly rectangular in the immediate channel; and it is on this account that the Croton and the Roquefavour aqueducts were made of the precise sections adopted in their respective cases.

---

* They were sometimes called cotelli, probably a corruption of coltelli, from their bearing knives, or large daggers.

Notwithstanding the improvements which have lately taken place in the application of science to the purposes of building, it is not possible to suggest any material improvement upon the system adopted by the Roman engineers in the construction of their covered conduits for town supplies. They kept the extrados of the covering of the vault at least two feet below the ground, or they covered the vault with earth of the same thickness when the conduit was raised above the surface; men holes were, however, left for the purpose of examination and repair, and from distance to distance chimnies for ventilation were introduced. Great pains were taken to ensure the impermeability and the solidity of the sides and bottom of the conduit, and the deposit of any accidental impurities the waters might contain. The Croton aqueduct was almost a literal copy of the old Roman works of the same description; and if we except the construction of some very unnecessary bridges, instead of using the modern system of cast iron reversed syphons, in passing some of the deep valleys, the whole of this work may be referred to with satisfaction. It may be added, that the Croton aqueduct is covered throughout its whole length, a precaution which ought almost always to be adopted in executing the conduits of town supplies.

The dimensions to be given to a channel for conveying water, merely by the velocity due to the fall of its entire length, are ascertained on the principles that the mean velocity is to the maximum velocity in the centre of the stream as 0·81 to 1·00, in the case of small channels, and as 0·835 to 1·00 in larger ones. Then as the area of the stream must be equal to the volume divided by the velocity, or as $S = \frac{Q}{v}$, provided the mean velocity be known, the area of the transverse section required to deliver a certain quantity of water may easily be ascertained. It generally happens that the width of a conduit is fixed by the peculiar circumstances of the case, as, for instance, in a mill-race, it will be affected by the width of the stream allowed to fall over the shuttle; in a canal, by the beam of the barges; and in a water supply, by the necessity for examination and repairs. As the best depth is that equal to twice the width, to some extent the only unknown element in the above equation is the velocity; and inasmuch as some of the conditions which limit the minimum velocity have been already stated, it may be as well here to add, that for a town water supply it is considered that it is desirable, in order to maintain a proper aeration of the waters, to secure a velocity of from 2 feet 8 inches to 3 feet per second.

In fact, it thus appears that the whole of the conditions, as to the section and fall of a channel, may be ascertained by the mean velocity of the water flowing in it, and that the formula given by Mr. Beardmore for calculating that velocity will, by transposition, furnish the elements of the other unknown quantities. His formula may be expressed thus: calling h the hydraulic mean depth in feet; i, the inclination of the channel, in feet per mile; and v, the velocity of the stream, in feet per minute; then $v = 55\sqrt{h.\,2\,i}$. Of course this quantity multiplied by the sectional area in feet gives the discharge in cubic feet per minute. The hydraulic mean depth, it may be added, is obtained by dividing the sectional area of the channel by the wet border. [HYDRODYNAMICS.]

CONE (Mathematics). In the most general sense, a cone is a surface formed by the motion of a straight line indefinitely extended in both directions, and which always passes through one given point (called the vertex). Any curve in space may be a guiding line (or directrix) through which the moving straight line may be made to pass.

But in common language the term cone is only applied to those general cones in which the directrix is a circle. Of these there are two kinds: the *oblique* cone, when the vertex is not in the axis of the directing circle (the axis being the perpendicular drawn to the plane of the circle through its centre); the *right* cone, in which the vertex is in the axis. The most prominent distinction between these two kinds of cones is this: that the oblique cone has two distinct sets of circular sections, whose planes are not parallel to each other [SUBCONTRARY], while the right cone has only one set of circular sections, all parallel to the directing circle.

The right cone is an infinitely extended surface, or consists of two cones (according to the most common notion) joined together by the vertex: but out of mathematics a portion of such cone is called a cone contained between the vertex and the directing circle, then called the *base*. In the rest of this article we shall use this meaning of the word.

The surface of a cone (in the common sense) is one half the circumference of its base multiplied by the distance from the vertex to the circumference of the base (called the *slant side*). Thus the diameter of the base being 10 inches, or the circumference 31·416 inches, and the slant side being 20 inches, the surface of the cone is $\frac{1}{2} \times 20 \times 31{\cdot}416$, or 314·16 square inches. The cone unrolled gives a sector of a circle, the angle of which, in theoretical units [ANGLE], is the circumference of the base divided by the slant side. Thus in the preceding instance $31{\cdot}416 \div 20$ or 1·5708 is the angle of the unrolled cone, which is a right angle.

The solidity of a cone is one third of the product of the area of the base and the perpendicular distance of the vertex from the axis. In the preceding instance the perpendicular aforesaid is

$$\sqrt{(\text{slant side}^2 - (\text{rad. of base})^2}, \text{ or } \sqrt{400-25}.$$

or $\sqrt{375}$, or 19·3649 inches. The area of the base is $3{\cdot}1416 \times 25$, or 78·54 square inches: and this multiplied by one third of 19·3649, or 6·455, is 506·976, the number of cubic inches in the cone. The centre of gravity of a cone is in the axis, at a distance from the centre of the base equal to one-fourth the distance of the vertex.

CONFARREATION. [MARRIAGE.]

CONFECTIONS; CONFECTIONARY. Confections, called also *Conserves*, are formed of fresh, generally succulent, vegetable substances, in a few instances with prepared chalk, as in the aromatic confection, preserved by means of sugar or honey. These confections were formerly much more numerous, and were examples of the polypharmacy prevalent among our ancestors: the number might be still beneficially reduced. The quantity of sugar required to prevent them from spoiling is so great as to disagree with delicate stomachs. In several instances the ingredients are ordered to be kept apart, or if associated in a dry state, the water or syrup is to be added when the preparation is intended to be used; as in the case of the aromatic, opiate, and almond confection. This is especially necessary in regard to the last; for if bitter almonds should be accidentally introduced, the presence of water might produce deleterious combinations.

When astringent substances such as roses are to be pounded, this process must be conducted in marble, not iron, mortars. The quantity of sugar is better to be excessive than deficient; and more is required in wet seasons than in dry. The conserves should be put into several small pots, rather than one large pot, which should be glazed with salt, as in Bristol ware, not lead. They should then be well closed, and kept in a dry cool place. Patent jars, of a very useful kind, are now manufactured for this purpose.

The chief confections are those of acorns, alkermes, almonds, bark, cassia, catechu, copaiba, hemlock, hops, ipecacuanha, jalap, succory, nitre, opium, orange flowers and peel, pepper, peppermint, resin, rose, rue, scammony, senna, &c.

Confections are generally medicinal; but *confectionary* mostly comprises sweetmeats having no relation to the medical art. The making of this confectionary may be regarded as one of the domestic arts, practised by highly paid persons in the mansions of the nobility and other wealthy families; but it is as a distinct trade that we here view it.

Sugar is the basis of all confectionary; and the processes of boiling, clarifying, candying, crystallising, refining, bleaching, and otherwise treating this important substance, must be well understood by a confectioner. The boiling is carrried to nine or ten different degrees or stages, technically known by the curious names of the "small thread," the "large thread," the "little pearl," the "large pearl," the "blow," the "feather," the "ball," the "crack," the "caramel," &c.; each stage is applicable to a particular purpose in confectionary; some for syrup, some for candy, &c. These processes are only an exemplification, on a small and delicate scale, of those which the reader will find described under SUGAR. The *syrups* form an important section of the confectioner's art. They are either the juices of flowers, or a decoction or infusion of the leaves, flowers, or roots of vegetables, impregnated with a sufficient quantity of sugar for their preservation in a liquid state. Many of these are made only for medicinal purposes; but others belong properly to confectionary, and comprise the agreeable qualities of raspberry, currant, cherry, mulberry, lemon, gooseberry, orange, liquorice, violet, pink, rose, marshmallow, coltsfoot, ginger, almond, pistachio, or other vegetable substance. Instead of syrups, a change in the mode of procedure will produce *candies*, in which the vegetable juice, decoction, or infusion is crystallised or granulated into a hard substance. A third mode of treatment produces *cracks*, so named from eating short and crisp, and including barley-sugar, sugar drops, kisses, acid drops and sticks, brandy balls, rock, hardbake, &c. Another variety comprises *lozenges;* these consist of loaf sugar in fine powder, mixed with various substances, made into a paste with dissolved gum, rolled out into thin sheets, and formed by means of tin cutting tools into small oval, square, round, or other shaped pieces. The substance chosen to mix with the sugar is the juice or some other extract of peppermint, rose, cinnamon, clove, lavender, ginger, nutmeg, rhubarb, tolu, saffron, marshmallow, vanilla, catechu, &c. *Pastile drops* are compounds of refined sugar with some kind of aromatic spirit, made into flat drops. *Comfits* mostly consist of seeds, such as those of the caraway, coriander, celery, or cardamom, enveloped in sugar; but sometimes the inner substances thus treated are fragments of cinnamon, almonds, barberries, preserved cherries, orange or lemon peel. Another department of the confectioner's art is that of making *jellies;* these are the juices of mucilaginous fruits, combined with sugar, rendered clear by filtering through a flannel bag, and boiled to the well-known jelly-like consistency: they are made from a large number of different fruits. *Marmalades* and *jams* are preserves of orange, lemon, apple, pear, quince, plum, or other fruit; the pulp of the fruit is boiled with sugar to the required thickness. *Pastes* are a similar kind of.marmalade or jam, but with an additional quantity of sugar, which permits of the substance being crystallised or candied into rings, knots,

&c.; these are much more numerous in kind than marmalades or jams.

Besides the compounds mentioned in the last paragraph, there are many others to which the attention of the confectioner is directed. *Preserved fruits* consist of the scarcely ripe fruit, boiled with sugar until the pulp has become thoroughly saturated with the saccharine agent; apricots, peaches, nectarines, figs, greengages, damsons, gooseberries, melons, lemons, oranges, pine-apples, cherries, grapes, currants, barberries, raspberries, pears, quinces, &c., as well as cucumbers, gherkins, orange or lemon peel, angelica, eringo, and ginger, may be thus treated. *Compôtes* bear some resemblance to the preserved fruits just noticed. *Brandy fruits* are fruits in which brandy as well as sugar is employed as a preserver. *Bottled fruits* are preserved in wide-mouthed bottles, and have undergone a careful process, by which air and moisture have as much as possible been removed from them. *Fruit waters*, for beverage, such as lemonade, raspberry-water, &c., in most cases consist of the juice of the fruit, treated with water, syrup, and lemon-juice. *Ices* are sweetened compounds which have been exposed to the action of a freezing mixture; they are made from a large variety of fruits and vegetable substances, and are classed into *ice-creams* and *ice-waters*, according to their consistence—some few being *ice-custards*. A good deal of apparatus, and much practical skill, are required for making ices. *Essences*—such as those of lemon, orange, bergamot, allspice, clove, vanilla, &c.—consist of the volatile or essential oils of fruits and other vegetable substances, extracted by means of spirits of wine, with or without distillation. A skilful confectioner possesses a wide range of knowledge in the treatment of liquids. He can distil or obtain *spirit* from various vegetable substances; he can extract the *essential oils*; he can prepare *distilled waters*, such as rose-water, cinnamon-water, &c.; he can make the numerous *liqueurs*, such as maraschino, kirchwasser, curaçoa, &c., by a peculiar application of spirit of wine to vegetable substances; or *ratafias*, which differ from liqueurs chiefly in being filtered and sweetened instead of distilled.

A peculiar part of the confectioner's trade is that which appeals to the eye, not to the sense of taste. He has to prepare table-ornaments, that may present much grace and beauty though cheap in the materials. He must know how to make gum-paste for ornaments; to prepare a paste that will bear to receive gold or colours on its surface; to form papier-mâché into rocks for a pièce montée, or into vases, &c.; to design complicated table ornaments, in which some knowledge of architecture and of sculpture may come to his aid; to lay his plans so that the parts of his temples, &c., *not* intended to be eaten may be made of cork, papier mâché, flock, paper, or gum paste, while the rest may comprise any of the sweetmeats which it is his trade to produce. The confectioner must also know how to prepare colours, and to combine them with his confections in proper kind and degree.

When the confectioner makes cakes and other articles in which flour is used, and which require the process of baking in an oven, he does so as a pastrycook, not as a confectioner.

The cheap confectionary now so largely sold in England has long been suspected of being adulterated; the price at which it is sold not being sufficient to pay for an honest course of dealing. Plaster and other substances are often used with the sugar; and poisonous dye-stuffs or pigments are used as colouring agents. Cases have been reported by medical practitioners, of children being poisoned by eating such sweetmeats. Towards the close of the year 1858, about twenty persons died, and two hundred were more or less injured, in and near Bradford, in Yorkshire, by eating sweetmeats; the maker thought he was using "daff," an adulterating preparation of plaster of Paris, as a cheap substitute for sugar; instead of which, through a mistake at a druggist's shop, he was using white arsenic.

An ingenious machine for making lozenges has lately been introduced by Messrs. Chase of Birmingham. A ball of prepared sugar, flavoured with the vegetable ingredient which may be selected, is worked up to the consistence of soft dough, and rolled on a board to the thickness of ordinary pie-crust. It is then laid upon a band, which carries it between a pair of rollers, after which it is flattened and passed through other rollers, until reduced to the thickness of a lozenge. The thin layer goes again upon the band, and is by it conveyed underneath a row of stamps. These stamps bear a motto, name, or other device, as may be chosen. The layer is then punched out by circular or other shaped cutters, which throw off clean glossy lozenges. The machine can produce three hundred pounds weight of lozenges in an hour.

CONFESSION means a solemn acknowledgment of some principle or fact. Hence the early Christians, who suffered imprisonment and other penalties from the Roman magistrates for having publicly declared their belief in the gospel, were called confessors. Others, in later times, acquired the same title from having embraced a life of austerity, or retired to some solitude or convent to do penance for their sins. Confession thus became synonymous with penitence, in which sense both words are understood by the Roman Catholics. The practice of confessing one's sins, either in public before the congregation of the faithful, or privately to a priest, dates undoubtedly from the earliest ages of the Church. In those times the Christians, scattered about the Roman world, and exposed to persecution, formed many small communities, living under the discipline of their presbyters, who knew every individual of their respective flocks, the members of which watched carefully over each other's conduct. Any gross irregularity, or any compliance with heathen rites by one of the flock, was sure to be known to the rest, and the offender was thereby subject to interdiction from Christian worship and communion. If he wished to be re-admitted to the communion of the Church, he must publicly acknowledge and repent of his guilt, and submit to the penance imposed by the presbyter. This appears to have been the original mode of confession. It does not seem to be clearly determined when the practice of private, or "auricular," was substituted for public, confession. Cyprian, who lived towards the middle of the third century ('Epist.,' Rom. 12), defines several kinds of sins for which penance ought to be done before the transgressor could be admitted to the communion; and in his treatise, 'De Lapsis in Persecutionibus,' he exhorts those who have fallen into heathen practices to confess their sins to the ministers of God, and thus unburthen their souls of their weight, "because this satisfaction and the remission by the priest are acceptable to God." Tertullian, who lived at the beginning of the same century, says ('De Pœnitentiâ,' ch. ix.) that penitence consists of three parts, confession, contrition, and satisfaction. In the eastern churches the custom of confessing sins before the assembled congregation was prevalent down to the fourth century; but the practice having led to scandal, especially on the occasion of a lady revealing that she had been seduced by a deacon, Nacterius, patriarch of Constantinople, abolished the custom, and removed the pœnitentiarius or priest ('qui præpositus erat pœnitentiæ') by whose advice the revelation had taken place. (Sozomen, 'Histor.,' lib. vii.) Some passages in Chrysostom have been urged against the obligatory practice of confession. In Homily 11, he says, "God commands that to him alone we should give account of our conduct, and to him we should confess;" which agrees with the principle and practice of the Protestant and reformed churches. Yet in his Homily of the Samaritan woman, he says, "He who blushes now to reveal his sins to a man, and will not confess, at the last day will be arraigned, not before one or two persons, but before the whole world.' In the fifth century, Pope St. Leo I., called the Great ('Epist.' Rom. lxxx., ch. v.), says that the priests ought not to enforce "public confession of secret sins," but that it is enough if the penitent confess them privately to a priest. This passage seems to throw some light on the transition from public to private confession. When, and under what circumstances, confession, either public or private, was deemed absolutely necessary for the remission of sins, is another subject of controversy. Innocent III., in the fourth Lateran council, A.D. 1215 (Canon 21), made confession (meaning auricular or private) obligatory upon every adult person once a year, and that continues to be one of the rules of the Roman Catholic church to the present day, which numbers penitence among the sacraments. The Council of Trent, in its catechism, defines it to be "a declaration by the penitent of his sins, made to a priest, in order to receive the penance and absolution." Penitence, therefore, consists of four parts, confession, contrition, absolution, and penance; and it is a positive doctrine of the same Church, that without the concurrence of all these parts or conditions, the sacrament is null and void. The penitent is also obliged to confess all the sins that he can recollect having committed and not confessed before, at least all the mortal sins, for Roman Catholic dogmatists draw a distinction between mortal and venial sins. By contrition it is meant that the penitent should fully repent of his guilt, and form at the same time a firm resolution not to sin again, without which repentance and resolution the absolution of the priest is of no avail, being always conditional upon a corresponding disposition on the part of the penitent. It is not therefore true, as it is often erroneously stated, that the priest can absolve from any sins by merely pronouncing the words, "Ego te absolvo," &c.; it is the penitent who, by his contrition and trust in the merits of the Saviour only, can give effect to the words of the priest, and in this respect the principle is common to all the Christian churches, except the formula of the absolution, which differs in some, while others omit it altogether. [ABSOLUTION.] The indispensable condition for obtaining absolution is often explained and inculcated from the pulpits and chairs of theology in Roman Catholic countries, though it happens of course that ignorant or weak people overlook or misconceive the absolute necessity of inward contrition, and think that by merely confessing their sins and reciting the formula of repentance with their lips, they have acquitted themselves of their part, and that the priest can do the rest. Again, the priest absolves "à culpa, sed non à pœnâ;" he removes the guilt, but not the punishment, here or hereafter; and accordingly Roman Catholics admit a purgatory. The penance which the priest imposes consists generally of satisfaction to be given if the penitent has injured any one in his property, honour, &c., in a manner that can admit of reparation, and also of prayers, abstinence, or other religious practices to be performed. The secrecy imposed on confessors is strict and unconditional; whatever be the crime of which a penitent may accuse himself, they are solemnly bound to keep it secret, under the most severe denunciations and penalties, both here and hereafter, that of excommunication *ipso facto* included. Notwithstanding the number of individuals who have exercised the office of confessors all over the Roman Catholic world, and the manifold temptations to which they are exposed, there are few authenticated instances of their having betrayed their trust. That there may be other inconveniences likely to result from private confession, is another question, which it is not our business to discuss. Every priest is not a confessor, although every incumbent of a parish is. The qualifications of age, studies, character, &c., required in a candidate for the office of confessor, the solemn engagements he enters into, and the formalities with which he is consecrated by the bishop, may be seen in the professional works of discipline of the church of Rome, and, among others, in the 'Bibliothèque Sacrée' des Pères Richard and Giraud, Paris, 1825, art. "Confession" and "Confesseur."

The box in which the priest sits in the church to hear the penitent is called the confessional. But the act of confession may be performed out of church, in private houses, in the field, in any place in short, provided it be not within hearing of any person except the priest and the penitent.

The Greek Church retains the practice of auricular confession, but differs from that of Rome in the form of the absolution. The Protestant and Reformed Churches, including those of England and Scotland, do not admit the practice, but recommend every one to confess his sins to God, and to repent in order to obtain forgiveness.

Confession is also the name given to the solemn profession of faith of various Christian churches which dissent from that of Rome, such as that of the reformed churches of France, in 40 articles, signed by Henry, king of Navarre, the prince of Condé, Coligny, and others, and presented to Charles IX. in 1561; that of the Helvetic reformed churches proclaimed in 1566 [ZWINGLI, in BIOG. DIV.]; that of the churches of the Netherlands, consisting of 37 articles, published in 1562, afterwards approved and signed by the members of the synod of Embden in 1571, and lastly examined and confirmed in 1691 by the synod of Dordrecht, or Dort, which condemned the five articles of Arminius. [ARMINIUS, in BIOG. DIV.]; and also that of the Protestant churches of Poland, printed in 1570 at Debrzin, and afterwards approved at the synod of Sendomir.

The most celebrated is the *Confession of Augsburg*, the name given to the profession of faith of the Protestant Lutheran Church, which was drawn up by Melancthon, with Luther's approbation, in order to be laid before the Emperor Charles V. at the great Diet held at Augsburg in June, 1530. It was on that occasion solemnly read in the German language by the Chancellor of Saxony, after which two copies of the Confession, one in German and the other in Latin, were delivered to the Emperor, bearing the signatures of John Elector of Saxony, George Marquis of Brandenburg, Ernest Duke of Luneberg, Philip Landgrave of Hesse, and Wolfgang Prince of Anhalt; besides those of the free town of Nuremberg, and other cities. The Confession was immediately afterwards printed, and, being translated into various languages, was spread over Europe. It has ever since continued to be the rule of the Lutheran Church in matters of faith. It consists of twenty-eight articles, twenty-one of which state the belief of the Lutherans on the principal tenets of religion; and the other seven consist of refutations of certain points of either dogma or discipline as maintained by the Roman Catholic Church, and on account of which the Lutherans separated from the communion of Rome. Zwingli and the other Swiss and French reformers did not subscribe to the Confession of Augsburg, as they differed from it on several points, particularly about the Lord's Supper. The style of the Confession is clear and fluent; the matter was chiefly supplied by Luther in the seventeen articles of Torgau, which he had presented to the Elector of Saxony the year before. Melancthon, while drawing up the Confession, had frequent conferences with Luther, who was then staying at Coburg, not far from Augsburg. The Papal theologians, headed by Faber, wrote a confutation of the Augsburg confession, which was likewise read before the Diet in August of the same year. Melancthon answered them in his 'Apology for the Augsburg Confession,' which was published in 1531, and which constitutes one of the books of authority of the Lutherans which were published, including the Confession, at Dresden, in 1580. Ernest Solomon Cyprian has written a good history of the Augsburg Confession, and Webber a 'Critical History' of the same, Frankfurt, 1783. (Schrœckh's 'Kirchengeschichte;' Mosheim's 'Ecclesiastical History, and Notes,' by Dr. Murdoch; and Neander's 'Church History.')

Some sepulchres of martyrs have been styled by antiquaries confessions; for instance, the subterraneous chapel, in which are the sepulchres of St. Peter and St. Paul, under St. Peter's at Rome, is called "the Confession of St. Peter."

CONFIRMATION is, according to the Church of England, "the rite of laying on of hands upon those who have been baptised, and are come to years of discretion." Such only are qualified to be confirmed as can say the Creed, the Lord's Prayer, the Ten Commandments, and the Church Catechism; to the end that children having learned what their godfathers and godmothers promised for them in baptism, they may themselves ratify and confirm the same; acknowledging themselves "bound to believe and to do" all which those persons undertook for them. It is affirmed in the sixtieth canon of the Anglican church, that confirmation is "a solemn, ancient, and laudable custom in the church of God, continued from the apostolic times." On the other hand, among the Protestant Dissenters it is regarded merely as the remnant of a Popish ceremony; with the assertion, that there is no more authority for that which is retained of it than for that which is rejected. The passages of scripture which are always adduced in support of this episcopal imposition of hands are the three following; namely, Acts viii 14-17; Acts xix. 6, and especially Heb. vi. 1, where ἐπίθεσις χειρῶν, "the imposition of hands," appears to be mentioned as an important rite of the Christian religion. But Dissenters disallow this mode of proving the propriety of the imposition of episcopal hands. They deny it to be a legitimate inference from the miraculous act of inspired Apostles to the act of modern bishops. What warrant, they ask, has a bishop to declare that God has given unto an assemblage of several hundreds of individuals "the forgiveness of all their sins," because they can say the Church Catechism? (See on this question, Towgood's 'Letters on Dissent;' De Laune's 'Plea for the Nonconformists,' &c.) Dr. Whitby observes that, unless the Apostles laid hands on all who were baptised, it makes nothing for confirmation; and that if they did, then Simon Magus received the Holy Ghost. The early fathers certainly believed the Holy Ghost to be indeed conveyed by the imposition of hands. "When we come out of the water," says Tertullian ('De Baptismo,' c. 7, 8), 'we are anointed with the holy chrism (perunguimur benedicta unctione), then we have the imposition of hands, which calls down the Holy Ghost (tradit Spiritum Sanctum Paracletum)." ('De Resurrec. Carnis,' c. 8; Hieron. 'advers. Lucif.,' tom. ii., p. 47; Cyprian, 'Epist.' 73-74 ad Jub., and 72 ad Steph.) Confirmation was originally thus administered immediately after baptism, of which it formed the concluding rite or complement, and was called βεβαίωσις; that is, confirmation; nor was there any exception to this time of administering it in the case of baptism in infancy. In the Greek church, and in Asia, it still accompanies baptism. The remonstrance of the Protestants at the Reformation caused the rite to be discontinued to infants, and to be administered only to adults; and afterwards the Council of Trent altered the time for confirmation to the seventh year.

The earliest mention, by the Fathers, of the use of chrism or sacred ointment in confirmation is believed to be in the passage of Tertullian 'de Baptismo,' already quoted (Bingham, b. xii., c. 3); but the church of Rome adduces the authority of the Epistle of James v. 14. The anointing the forehead with this holy unction, which was composed of oil and balsam, constituted the first act of the ceremony of confirmation. The consignation, or signing with the sign of the cross, was the second; and the third and last was the imposition of the bishop's hands, with the invocation of the Holy Ghost. The person was then qualified to partake of the eucharist. Confirmation in the Greek church is named μυρὸν, "ointment;" χρίσμα, "unction;" μυρὸν τοῦ χρίσματος; σφραγὶς, "the seal;" and ἐπισφράγισμα. In the Roman church this rite is one of their seven sacraments, and it consists in the bishop's anointing the forehead of the person, saying, "A. B., I sign thee with the sign of the cross, and confirm thee with the chrism of salvation, in the name of the Father, and of the Son, and of the Holy Ghost." The bishop then gives a slight blow on the cheek, and concludes with pronouncing the words Pax tecum, "Peace be with thee."

Lord King, in his 'History of the Primitive Church,' p. 91, has shown that confirmation was originally the same thing as absolution, and that it was frequently repeated on the same individual. On the reiteration of the rite, see also Morinus 'De Pœnitentiâ et Ordinatione,' l. 9.

The Puritan contempt for the hierarchy occasioned confirmation to become greatly neglected after the Protestant Reformation in England (Hooker, l. 5, 66; Bishop Hall's χειροθεσία); but subsequent to that period the Church of England has observed the rite with much more strictness than the Lutheran or any other church. In Germany it was not generally adopted till the middle of the 18th century.

Du Pin ('Study of Divinity,' p. 216) gives a numerous list of writers on the subject. (Bingham's 'Origines Ecclesiasticæ,' vol. iii., p. 286, *et seq.*; Hammond 'De Confirmatione;' Bishop Parker 'on Confirmation;' Goar's 'Euchologia,' p. 368; Gratian, 'Concordantia Discordantium,' part iii.)

CONFIRMATION (in law). [DEED.]

CONGÉ D'ESLIRE (or D'ÉLIRE), a term in Norman French, literally signifying "leave to elect," which is appropriated to the king's writ or license to a dean and chapter to elect a bishop, at the time of the vacancy of the see. The right of nominating to bishoprics was in most countries of Europe enjoyed by the temporal sovereigns, with little opposition from the ecclesiastical authorities, until the 11th century, when a contest began between the popes and the monarchs of Europe, which, in the next century, ended in the latter being compelled to surrender this important privilege to the clergy. Father Paul ('Treatise of Benefices,' c. 24), says that between 1122 and 1145, it became a rule almost everywhere established, that bishops should be chosen by the chapter. In England, by the constitutions of Clarendon, in 1164, the election was vested in the chapters, subject to the king's approbation of the object of their choice. The right of election was afterwards formally surrendered to the chapters by a charter of King John, by which however he reserved to himself, among other things, the right of granting a congé d'eslire, and of confirming the choice of the chapter. This grant of freedom of election was expressly recognised in Magna Charta, and also by a subsequent statute, 25 Ed. III., stat. 6, which was passed for the purpose of preventing the popes from interfering with the elections to dignities and benefices in England.

So the law stood until the passing of 25 Henry VIII., c. 20, which, though repealed in Edward the VI.th's reign, was afterwards revived, and by which episcopal elections are regulated at the present day. By this Act it is provided that upon every avoidance of an archbishopric or bishopric the king may grant to the dean and chapter a license under the great seal to proceed to the election of a successor, and with the license a letter missive containing the name of the person whom they are to elect. If the dean and chapter delay their election above twelve days after receiving the license, the king may, by letters patent, nominate any person whom he pleases to the vacant see; if they delay the election beyond twenty days, or elect any other person than the candidate recommended by the king, or do anything else in contravention of the Act, they incur the penalties of a præmunire. Bishoprics in Ireland are donative by letters patent, without a congé d'eslire. ('Irish Stat.,' 2 Eliz., c. 4.)

CONGESTION, a preternatural accumulation of blood in the capillary vessels of the sanguiferous system, attended with disordered function of the organs in which such an accumulation takes place. The main functions of the sanguiferous system are performed by the ultimate divisions of the blood-vessels, called, from their hair-like minuteness, *capillaries;* the office of the main trunks and the larger branches of the blood-vessels being merely to convey to the capillaries the material acted upon by them in the various processes which they perform. In the natural and healthy state of an organ, the arterial capillaries in which the arterial trunks that supply it with arterial blood terminate, receive a certain quantity of blood; retain that blood a given time; and then transmit it with a given impetus into the venous capillaries, which in their turn convey it into the larger venous branches, and these to the heart with a given degree of velocity. Upon this transmission of the blood to and from the organs in a given quantity and a given time, depends the balance of the circulation; upon the due balance of the circulation depends the healthy condition of the organic processes; and upon the healthy condition of the organic processes depends the sound performance of the animal functions.

Of the mode in which the balance of the circulation is disturbed by the preternatural accumulation of blood in the capillary vessels, some conception may be formed by observing the phenomena that take place when a mechanical or chemical irritant is applied to a transparent part of the animal body; and when such a part is brought under the field of the microscope, so that the circulation in the minute vessels can be distinctly seen. In this case, the first phenomenon observable is a quickened circulation in the part, and the consequent determination to it of a greater quantity of blood; next, after a time, the blood-vessels are seen to dilate and to become turgid with blood; and in the third place, the flow of blood through these distended vessels is manifestly retarded; and ultimately, if the irritating cause continue to operate with a certain degree of intensity, the circulation is wholly stopped. The quickened circulation, the first phenomenon that takes place, is occasioned by the action of the contractile power inherent in the coats of the capillary vessels, excited in an inordinate degree by the application of the unusual stimulus. The dilatation of the capillary vessels, the subsequent event, arises from a diminution of the vital power of the coats of the vessels, from the over-excitement produced by the irritating cause.

The blood-vessels in this state are commonly said to have lost their tone; to be debilitated or weakened. The consequences of this loss of vital power in the living tissues that form the walls of the blood-vessels, are the engorgement of the vessels, the impeded, retarded, or abolished circulation of blood through them, and the disordered or suspended function of the part affected.

From the preceding statement, a distinct conception may be formed of that morbid condition of the blood-vessels, to the designation of which the term congestion is commonly applied. How greatly such a condition of the blood-vessels must disturb their natural functions, and consequently how powerful an agent it must be in the production of disease, it is also easy to conceive. But pathologists have hitherto made but slight progress in determining with precision the nature of the morbid changes which take place, either in the blood-vessels themselves, or in the tissues in which, as a consequence of this affection, an alteration of structure is sometimes ultimately superinduced.

From an observation of the phenomena connected with the state of congestion, it is usually distinguished into passive and active. When there is merely an accumulation of blood in the distended and debilitated capillaries, without any other manifest morbid phenomenon, the state is called simple congestion; and this state of congestion is commonly said to be passive. But when to this accumulation of blood there are superadded certain phenomena which accompany and which characterise another morbid state, namely, inflammation, the congestion is termed active. In active congestion, the blood-vessels themselves are in a state of excitement; the preternatural quantity of blood they contain is determined to them by their own inordinate activity; they are in a condition not of diminished but of exalted vital energy. In passive congestion, on the contrary, the coats of the vessels are destitute of their natural tonic, vital resistance; yield readily to the current of blood which is determined to them, or unable to pass on the current they receive, the blood accumulates in them and distends them. Active congestion, according to this account, however, can be distinguished by no certain and even no appreciable character from inflammation, a state which is always supposed to be different from congestion. [INFLAMMATION.]

The tissue of the body in which the state of congestion is most apt to occur, is the cellular, and more especially in the lax and little cohesive condition in which this tissue forms the parenchyma of the different internal organs, as the brain, the lungs, the liver, the spleen, the kidneys, and so on. A congested state of their blood-vessels is also peculiarly apt to occur in the mucous membranes, and more especially in the mucous membranes of the bronchi and air vesicles of the stomach and the alimentary canal, and of the ovaria and uterus. But besides these, other and less yielding structures, as the serous and fibrous membranes, the skin, and even the muscles, may be affected with congestion, after the operation of causes which have exhausted the vital energies of the system in general, or which have diminished the vital cohesion of these structures in particular.

Congestion, when present to any considerable extent, and when continuing for any length of time, disorders the function of the organ in which it takes place. The signs of this disordered function are signs from which it is inferred that congestion is present. If, for example, the blood-vessels of the brain be in a state of congestion, the activity and energy of the cerebral functions will be diminished, indicated by dulness, heaviness, forgetfulness, inaptitude for mental labour, giddiness, lethargy, and so on; and if the congestion be in great intensity, it may produce all the symptoms of coma and even of apoplexy. [APOPLEXY; COMA.] If the blood-vessels of the liver be in a state of congestion, the secretion of bile will be disordered; altered in quality, diminished in quantity, or entirely suppressed. If the blood-vessels of the mucous membrane of the air passages be in a state of congestion, it will occasion uneasiness in the chest, difficulty of breathing, cough, &c.

Congested states of these and other organs are exceedingly apt to occur in the progress of other diseases, more especially in the different types of fever, the character of which they modify, and the severity and danger of which they always greatly increase. There are fevers, indeed, and those of the very worst kind, that is, the most intense and the least under the control of any known remedies, in which a high degree of congestion of the blood-vessels of the brain, of the lungs, of the liver, or of the mucous membrane of the intestines, is among the very first appreciable morbid conditions of the system; but in general such a congested state of the blood-vessels is consequent upon preceding morbid conditions of the organs; conditions by which the vital energies of the blood-vessels have been exhausted.

The appearances presented by congested parts after death, vary with their structure and with the degree and duration of the affection. The capillary arteries and veins are turgid with blood; the blood they contain is of a darker colour than natural; hence the colour of the organ, the seat of the congestion, is darker in proportion to the intensity of the affection; it is also commonly more or less swollen, and the cohesion of its tissues is diminished, so that they are more readily torn than when in a healthy condition. In some organs, indeed, as in the liver and the spleen, when the congestion is in an extreme degree, the cohesion of the component tissues is so much lessened that the organs are broken down on the slightest pressure.

Anything may be the cause of congestion which diminishes the vital energy of the capillary vessels; or which changes, beyond a certain limit, the quantity and quality of the blood they contain. If the vital energy of the capillaries be diminished, they cannot maintain the tension necessary to prevent distension of their parietes, and a consequent preternatural accumulation of blood. If the quantity and quality of the blood they contain be altered, their natural stimulus may be so deficient as not to excite, or so excessive as to exhaust them. For the treatment of congestion, see INFLAMMATION.

CONGREGATION most commonly signifies an assembly of persons for the purpose of public worship and religious edification. It denotes more particularly a number of ecclesiastics constituting a legislative and executive body; and in this acceptation it is applied chiefly to certain boards of administration consisting of cardinals and of prelates, or aspirants to the cardinalship in Rome. These congregations serve as a check on the papal authority; for though their proceedings are usually sanctioned by the pope, he cannot, without alleging the weightiest reasons, put a veto on them. The whole number of these congregations is twenty-one; that is, fifteen for spiritual and six for temporal purposes. Congregation is also used to designate a company, society, or fraternity of monks forming a subdivision of an order, as the congregation of the Oratory, or of Cluny among the Benedictines. The Congregation of the Lord was an appellation assumed by the Scotch Presbyterian Reformers, who called the Church of England the congregation of Satan. They appeared first in 1557, under the Earl of Argyle, and were subsequently led by John Knox.

Congregationalists are those who compose the congregations which assume an independence not only of the ecclesiastical control of the established hierarchy, but of all authority extraneous to the constituency of the congregation itself. They may therefore in general be said to be identical with the Independents. They are said by some to have appeared first in 1616, under the conduct of Mr. Jacob. (Evans's 'View.') But they are generally considered to be of the same origin as the Brownists, who appeared in 1600. [BROWN, ROBERT, in BIOG. DIV.] The real founding of this sect is attributed to Mr. Robinson, in 1640, and the following passage from his 'Apology' (c. 5, p. 22) is adduced as their leading maxim: "Cœtum quemlibet particularem esse totam, integram et perfectam ecclesiam, ex suis partibus constantem immediatè et independenter sub ipso Christo." It is said that they adopted the name of congregational brethren, and congregational churches, to avoid the odium of sedition and anarchy which was charged upon them as the Puritan regicides of Charles I. Cromwell made use of them as a political check on the Presbyterian party. (See 'Declaration of the Faith and Order owned and practised by the Congregational Churches in England,' 1658.) In the six New England states of North America, which were colonised by the English Puritans, the Congregationalists are very numerous; and in several other parts of the Union their numbers are much larger than those of other sects. Their creed and the rules of their democratic government are given fully in their 'Platforms of Discipline.' They believe in "The Trinity; Predestination; Total Depravity; Particular Redemption; Effectual Grace and Final Perseverance;" and maintain that "Every congregation of visible saints, furnished with a pastor, is under no other ecclesiastical jurisdiction whatever."

(Mosheim, cent. 17, § ii. part ii.; Neal's *Hist. Puritans;* Burnet's *Hist. Own Times;* Adam's *Dict. of Religion.*)

CONGRESS, an assembly of envoys delegated by different courts with powers to concert measures for their common good or to adjust their mutual concerns. The term is given also to a meeting of sovereign princes which is held for the like purpose. The delegates from the Assemblies of the British colonies who met at New York, 7th October, 1765, to consider their grievances, called their assemblage a Congress. A second congress, which assembled in June, 1774, and sat for eight weeks, published a Declaration of Rights. Another congress met in May 1775, which proceeded to organise the military and financial resources of the colonies; and thus these assemblies of delegates exercised the functions of a supreme government, and under their authority the war of independence was brought to a successful termination. In 1789 the constitution was re-organised, and a congress of two houses was formed. [UNITED STATES OF NORTH AMERICA, in GEOG. DIV.] The meeting of envoys or plenipotentiaries which precedes a treaty of peace is sometimes called a Congress; but the term is more generally applied to such meetings when they have to settle, either before or after the peace, an extensive plan of political arrangements and re-organisation. This was the business of the Congress of Vienna in 1815. Sometimes a meeting of sovereign princes or plenipotentiaries takes place to concert a certain line of political action, and this is also commonly termed a Congress. Examples of these are furnished by the Congress of Carlsbad, 1819; of Troppau and Laybach, 1820, and of Verona, in 1822.

CONIA. The active principle of hemlock appears to be an alkaloid termed *conia*, which, unlike most vegetable alkaloids previously known, is not fixed and crystalline, but volatile and oleaginous. It has been obtained both from the leaves, and fully developed but still green fruits. Its activity is increased by union with acids, both mineral and vegetable; a circumstance which shows the impropriety of giving vinegar as an antidote in cases of poisoning by hemlock, when any of the substances is yet present in the stomach. Conia is sparingly soluble in water, to which it imparts its odour and taste. It also combines with about a fourth of its weight of water to form a hydrate of conia. The salts of conia are very soluble in water, but rapidly undergo decomposition, so as to become innocuous; water is therefore an improper vehicle for their exhibition. When exposed to the air it quickly contracts a dark brown colour, and is slowly resolved into a resinous matter, with the disengagement of ammonia. This change takes place more promptly under the co-operation of heat; but even at common temperatures it is so apt to ensue, that unless the alkaloid be kept very carefully excluded from the air, discoloration will take place in a few hours. Though conia exists in the plant in combination with coniic acid, which may render it less alterable, yet its proneness to decomposition is so great, that either by time or the application of a considerable degree of heat, it may be entirely dissipated; which accounts for the inertness of old leaves, and of most extracts which have not been prepared with the greatest care. Geiger says that the dried leaves do not contain conia; a statement which, if correct, leads to the conclusion that conia, though the most powerful, is not the only efficient agent in hemlock.

Conia appears, from the experiments of Geiger and Christison, to be a deadly poison to all animals. It acts with the most extraordinary rapidity; but if it fail to kill, its injurious action passes quickly away, and perfect recovery follows. It acts through every texture of the body where absorption is readily carried on. It acts as a local irritant; but its ultimate and fatal energy is chiefly exerted on the spinal chord, to which its influence is conveyed by entering the blood and producing on the inner membrane of the blood-vessels a peculiar nervous impression, which is instantly conveyed by sympathy along the nerves to the organ remotely and ultimately affected. "It exhausts the nervous energy of the spinal chord, producing general muscular paralysis and asphyxia from relaxation." The heart, however, is exempt from this general paralysis, contracting vigorously for a long time after all motion and respiration and other signs of life are extinct. It is, therefore, extremely probable, as suggested by Dr. Christison, that where a dose is not so large as to produce immediate death, the carrying on of artificial respiration and administering vital stimulants, might save the life of the patient, especially as the action of the poison is so transient, and incapable of producing a permanently injurious impression.

Infusion of galls, or strong black tea, if speedily administered, might prove an antidote.

CONIC SECTIONS, the curves formed by the intersection of a circular cone and a plane, either oblique or right.

Though the name of conic sections still remains, yet the interest which attaches to these curves, and the method of treating them, has no longer any reference to the accident from which they derive their name. The Greek geometers, in pure speculation, occupied themselves with the different methods in which a cone may be cut, simply because the conical surface (with the cylindrical and spherical) came within the restrictive definitions under which they had placed geometry. [GEOMETRY.] The works of APOLLONIUS and ARCHIMEDES [BIOG. DIV.] are the first in which these sections were treated; and their subsequent history is nothing but that of the addition of a few remarkable properties, until the discovery that the path of a projected body in an unresisting space is a parabola, and that of a planet round the sun an ellipse. [GALILEO, and KEPLER, in BIOG. DIV.] Since that time we might as well attempt to write the history of mathematics and physics as that of conic sections in their results and consequences; and from that time we have nothing to say of them merely as *conic sections*.

Some sections of a cone are considered in elementary geometry; for a plane may meet a cone in a point, or in a single straight line, or in two intersecting straight lines, or in a circle. But the curves which are peculiarly conic sections are, the oval made by a plane which cuts the cone entirely on one side of the vertex, called the ELLIPSE; the indefinitely extended modification of this when the plane becomes parallel to any one slant side of the cone, called the PARABOLA; and the curve which is partly on one side and partly on the other of the vertex, formed by a plane which cuts both surfaces of the cone, called the HYPERBOLA. To these names we refer for the specific properties of the sections.

Algebraically considered, the *conic sections* are the *curves of the second degree*, meaning the curves belonging to such equations between co-ordinates are of the second degree. Thus, x and y being co-ordinates, oblique or rectangular, the general equation

$$a\,x^2+b\,x\,y+c\,x^2+d\,y+e\,x+f=0,$$

may, by properly assuming a, b, c, &c., be made the equation of every possible section of a cone by the plane in which the co-ordinates are measured. As very many elementry works do not fully discuss the conditions under which the preceding equation represents the different sections, we subjoin the following from the 'Camb. Phil. Trans., vol. v., p. 89. In the following list, θ means the angle made by the co-ordinates:—

$$\text{Let } v_1=a+c-b\cos\theta \qquad v_2=4\,a\,c-b^2;$$

$$w'=\frac{c\,d^2+a\,e^2-b\,d\,e}{b^2-4\,a\,c}+f,$$

and in the case where v_2 and $c\,d^2+a\,e^2-b\,d\,e$, are both $=0$, let

$$w''=\frac{4\,a\,f-d^2}{4\,a}=\frac{4\,c\,f-e^2}{4\,c}.$$

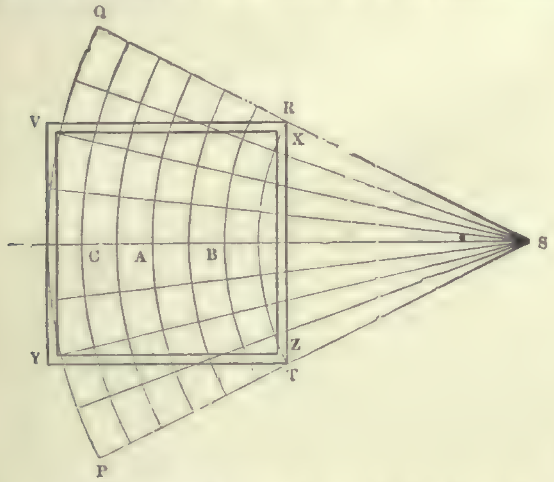
In the following table, p means either sign, + or —, but in the same line, n means the other sign; a dotted line means that the sign of the expression at the head of the column need not be considered. The word line by itself means straight line.

W'	V_2	W''	V_1	Name of the Section.
p	+		p	Impossible.
p	+		n	Ellipse.
p	—		..	Hyperbola.
a	0		..	Parabola.
0	+		..	Point.
0	—		..	Intersecting lines.
$0 \div 0$	0	p	p	Impossible.
$0 \div 0$	0	p	n	Parallel lines.
$0 \div 0$	0	0	..	Line.
$0 \div 0$	0	n	..	Line.

Thus if w' and v_1 both have the same sign, and v_2 be positive, the equation cannot be satisfied at all; but if w' and v_1 be of different signs, and if v_2 be positive, the equation is that of an ellipse. We may add that $v_1=0$, indicates an equilateral hyperbola. [HYPERBOLA.]

The general properties of the sections are numerous and interesting, but we shall only mention one, because it is the most convenient as a general definition of the curves, combining them at once with each other, in a manner to which algebra is easily applied. If a point move in such a way that its distance from a given point (called the *focus*) always is the same fraction of its perpendicular distance from a given right line (called the *directrix*), then the curve traced out is an ellipse, parabola, or hyperbola, according as the given fraction is less than, equal to, or greater than, unity. We are convinced that no method of deducing the properties of these curves can be very successfully applied in the case of beginners, unless it involve the foci in the definition. The properties of these points do not readily show themselves either in the deduction from the cone or from the general algebraic equation.

CONICAL PROJECTION, a method of describing a representation of a part of a sphere upon a plane. A sphere cannot be unrolled into a plane, as can every cone or portion of a cone. If a cone be described which touches a sphere in a small circle, and if the several points of the sphere be then projected upon the cone by lines drawn through the centre, the parts adjacent to the small circle of contact will be projected into figures very nearly similar to the originals. If the degrees of latitude, which are very nearly equal, be made actually equal, no injurious effect will be produced on the map. Suppose, for instance, it is required to draw the map of a country contained between two given longitude circles, and two given parallels of latitude.



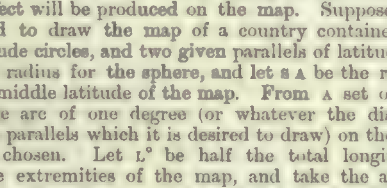
Take any radius for the sphere, and let S A be the radius × cotangent of the middle latitude of the map. From A set off A B, A C, &c., equal to the arc of one degree (or whatever the distance may be between the parallels which it is desired to draw) on the great circle of the sphere chosen. Let L° be half the total longitude contained between the extremities of the map, and take the angles A S P and A S Q, equal to L° × the sine of the middle latitude. Divide the angle Q S P into as many parts as there are degrees (or other required intervals of longitude lines) in L; then Q R T P is the map required, and V X Y Z such a portion as is usually exhibited on a sheet of paper.

If, instead of the tangent cone, it be required to project upon the cone formed by the revolution of the chord which joins the two extreme points of the map on the sphere, let l and l' be the least and greatest latitudes, and let

$$\text{S R} = \text{radius} \times \cos l' \div \sin \tfrac{1}{2}\,(l+l')$$
$$\text{S Q} = \text{radius} \times \cos l \;\div \sin \tfrac{1}{2}\,(l+l')$$

the rest is as before.

There are two modifications of this principle which it will be convenient here to notice,—the projection used by Flamsteed, and that adopted by the French government in their recent maps. In Flamsteed's projection the degrees of latitude are equal, and the parallels of latitude are perpendicular to the middle longitude circle, which is a vertical right line. But the degrees of longitude are made in every parallel to bear the same proportion to the degree of latitude as on the globe; so that the meridians are, in fact, curves, the ordinates of which are as the cosines of the abscissæ.



In the French government maps the same plan is adopted, with this exception, that the parallels of latitude are the circles of the conical projection, and the degrees of latitude are all equal (the oblateness of the earth may be allowed for, if thought necessary); the degrees of longitude are then set off on the parallels of latitude in the same proportion as in Flamsteed's projection.

CONINE, *Conicine, Conia, Conicina* ($C_{16}H_{15}N$). An alkaloid obtained from hemlock (*Conium maculatum*). It is procured from the seeds or fresh leaves of the plant by distillation with water holding some potash in solution. When pure it has the following properties: It has the appearance of a colourless volatile oil, and is lighter than water, its specific gravity being 0·89. Its odour is powerful, diffusible, and repulsive, somewhat like that of hemlock itself. It is intensely acrid to the taste. It has a strong alkaline reaction on turmeric paper. It combines readily with and neutralises acids; and some of the salts which it forms with them have been obtained in a crystalline state. It is sparingly soluble in water, and what is remarkable is, that it is more soluble in cold water than in hot. It imparts its odour and taste to water. Alcohol mixes with it in all proportions; and it also dissolves readily in ether. With about one-fourth of its weight of water it forms a hydrate. By exposure to the air it quickly becomes of a dark colour, and spontaneously decomposes with the evolution of ammonia. Its boiling-point is 370° Fahr. It distils, however, with boiling water, but suffers partial decomposition.

It is one of the most virulent poisons known, destroying small animals by a very small quantity and in a very short time.

Hemlock also appears to contain a second base, *methyl-conine* ($C_{18}H_{17}N$); whilst, by acting upon conine with iodide of ethyl, a third base, *ethyl-conine* ($C_{20}H_{19}N$), may be obtained.

CONJUGATE. This word is used in several branches of mathematics in a sense which (with one exception, and that might easily be abolished) may be described as follows: Two points, lines, &c., are called conjugate, when they are considered together in any property in such a manner that they may be interchanged without altering the way of enunciating the property. Thus, if A C be to C B as A D to D B, C and D are conjugate points with regard to this property.

If we write D where C now is, and C for D, the property is still expressed in exactly the same way. We have other instances in conjugate diameters, conjugate hyperbolas [ELLIPSE; HYPERBOLA], conjugate foci [LENS; MIRROR].

The instance of exception is the conjugate point of a curve, meaning a single point lying by itself, whose co-ordinates satisfy the equation of the curve, without its actually being on any continuous branch of the curve. [CURVES, THEORY OF.] It would be better to call this point *conjunct* than use a term which destroys the generality of language. But the best term, in our opinion, would be *evanescent oval.* [See the article already cited.]

CONJUGATION of a verb is a term in Grammar, denoting the addition of suffixes or prefixes to the crude, or elementary form of a verb, for the purpose of denoting respectively, person, number, time, state, mood, and what is generally understood by voice. In the English language prefixes are commonly used for these purposes, and these prefixes are not printed in connection with the verb, though the voice presents them in one mass. Thus, *I shall have heard,* as pronounced, is not less one word than the Latin *audi-v-er-o.* In this example, therefore, *I, shall, have,* are virtually prefixes, and the letter *d,* a contraction from *ed,* or rather *de,* is a suffix attached to the simple verb or crude form *hear.* In the ancient languages, such as Greek, Latin, and Sanscrit, suffixes are commonly but not exclusively preferred.

The suffixes which denote the *persons* are the personal pronouns more or less corrupted. Thus, in Latin, *egomet* is the full form of the pronoun which signifies *I;* but as three syllables would be too long for a term in such frequent use, and this inconvenience in the present instance would be aggravated by an appearance of egotism, the word was shorn of its exterior letters, and at the utmost the three middle letters, *ome,* were attached to the verb. We see them in the Greek form *tupt-ome-s,* or *tupt-ome-n,* "we strike." In the Latin, the vowels were corrupted, so that instead of *ome,* either *umu* or *imu* occur, as in *-umu-s,* "we are;" *poss-umu-s,* "we are able;" *scrib-imu-s,* "we write." The old German has nearly the same suffix in *war-ume-s,* "we were;" *bir-ume-s,* "we be." Again, the three letters, *ome,* deprived of the last vowel, became *om,* as Greek, *tupt-om-ai,* "I strike myself;" *um,* as Latin, *s-um,* "I am;" *poss-um,* "I am able;" also *am,* as seen in *inquam,* "I say;" and *on,* as Greek, *e-tupt-on,* "I was striking." But the first vowel might disappear instead of the last. Thus, *me* is the form which appears in the Greek *es-me-n,* or *es-me-s,* "we are;" *mi* is used in *es-mi, ei-mi,* "I am;" *di-do-mi,* "I give," &c. Sometimes the *m* is all that appears, as *scribeba-m,* "I was writing." In Greek, this final *m,* by a principle constantly observed in that language, becomes an *n,* as *ē-n,* "I was;" *etetuphei-n,* "I had struck." Another form of the suffix is *o,* instead of *om,* which is common both in the Greek and Latin,—as Greek, *tupt-o,* "I strike;" Latin, *scrib-o,* "I write." Finally, all trace of the pronoun at times disappears, and the defect ceases to mislead because the other persons have their characteristic terminations. Thus the Greek tenses, *etupsa,* "I struck," *tetupha,* "I have struck," and *etetuphea,* "I had struck," contain no remnant of the pronoun. In the English language there are some slight traces of the personal suffixes, which existed in full perfection in some of the older forms of the Teutonic languages. The word *am,* for example, has a remnant of the first person suffix in its final *m.*

The second person in the Greek and Latin languages was *su* or *tu;* in German, *du;* and in English, "thou." Accordingly, we find a sibilant attached to the verb to denote the second person, as in the Greek, *es-si,* "thou art;" *ois-tha,* "thou knowest;" *tupt-es-ai,* "thou strikest thyself;" in the Latin, *scrib-is,* "thou writest;" and in the

English termination *est* in *knowest*, *strikest*. But as the Latin form has a *t* instead of an *s*, *tu* not *su*, so the *t* occasionally appears as in Greek, *tupt-ete*, "you strike;" Latin, *scribiti-s*, "you write;" and in the English, *art*, "thou art."

The third person is an indefinite term, and the suffix which denotes it is derived from *to*, signifying *this*, which is the full form of the Greek article; and again appears, on the one hand in Latin, in the derivatives *tam*, *talis*, *tantus*, *tot*, *tum*; and on the other, in the English *the*, *this*, *to-day*. It is therefore as general as the English article *the*, and may denote indifferently, *the man*, *the woman*, *the thing*; in other words, *he*, *she*, *it*. It appears as a suffix in the Greek *ες-τι*, "he is" (Sanscrit, *as-ti*); *τυπτ-ετ-αι*, "he strikes himself;" in the Latin, *es-t*, "he is;" *scrib-it*, "he writes;" and in the obsolete form of the English language, *walk-eth*, now corrupted into *walks*.

Suffix of *number*. If a sign be employed to denote plurality, the absence of that sign will be a sufficient indication of the singular. Now the suffixes of plurality in English are *s* and *en*, as in *dogs*, *oxen*. The same are employed in Greek and Latin, as, first person, Greek, *τυπτ-ομε-ς*, or *τυπτ-ομε-ν*; Latin, *scribimu-s*; second person, Latin, *scribiti-s*. The Greek has dropped the *s*, as in *τυπτ-ετε*, a corruption probably of *τυπτ-ετε-ς*; just as the Latin imperative *scribite* must be looked upon as reduced from *scribitis*. For the third person we must have in view the older form, *fanti* (*φαντι*), "they say;" or rather *fantin*, for this final *n* is an essential part of the word, and not, as is commonly taught, a meaningless addition. Thus the four letters *ntin* represent the suffix, of which the final letter denotes plurality, and the remainder is but a variety of the article *to*, "this." The change of the *t* to *n* in this pronoun is not rare, as may be seen in the Latin *nam* and *num* (*nunc*), which in origin are but varities of *tam* and *tum* (*tunc*); and if *n* and *t* are interchangeable, *a fortiori* is *nt* interchangeable with either.

Time or tense (Fr. *temps*) divides itself into past, present, and future, where again the idea of present time will not require any peculiar distinction, if the ideas of past and future have their proper symbols. The past time appears to have had for its characteristic either the prefix, *e*, or the suffix, *a*. The former appears in the Greek, *e-tupt-on*, "I was striking;" *e-tup-sa*, "I struck;" *e-tetuph-ea*, "I had struck." The second appears in two of the Greek forms just enumerated, and in the Latin *scribeb-a-m*, "I was writing;" *er-a-m*, "I was." A very distinct example of a future suffix appears in those European languages which are derived from the Latin. Thus, in the French, *écrir-ai*, we have really two distinct words, the infinitive, *écrire*, and *ai*, the present tense of *avoir*, forming altogether, *écrir-ai*, "I have to write," that is, "I shall write." This origin of the French future is placed beyond a doubt by a comparison with the Spanish and Italian. (See Key's 'Alphabet,' p. 123, &c.)

By the term *state*, which stands forth in the series of suffixes which have been included in the definition of conjugation, it was intended to denote the notions of perfect and imperfect action. Here again one suffix is sufficient, and the notion of completeness is variously marked: 1st. By a doubling of the verb upon itself. The purest example of this is presented in the Gothic, as *laia*, "I laugh;" *lailó*, "I laughed;" *stauta*, "I strike;" *staistaut*, "I struck." The Greek have perfects formed upon this principle in *te-tupha*, *ge-grapha*; the Latin in *te-tul-i*, *de-d-i*, *spo-pond-i* (for the less easily pronounced *spo-spond-i*). And in our own language there is strong reason for believing that such is the origin of *did*, the perfect of *do*. Out of the same principle grows the formation of the perfect by a long vowel, *vēni* being probably a contraction from *vĕ-vĕn-i*. 2nd. By adding the simple tenses of the verb *ĕs*, "be," with an interposed *s*, which by a bold yet highly probable theory may be regarded as the ordinary genitival suffix signifying "from." Thus, *scrip-s-eram* would be "I was from writing," or "I had written;" *scrip-s-ero*, "I shall be from writing," or "I shall have written." So *scrip-s-istis* (*istis* for *estis*), "ye are from writing," or "ye have written." As *s* is a letter very apt to vanish from language, we must not be surprised at its non-appearance in such words as *ven-eram*. Again, the *r*, which presents itself in so many perfects of the Latin language, as *amaveram*, *monueram*, is probably but the old *w*, which once formed a part of the verb *es*, "be;" witness the German *wes-en*, "existence," and our own *was*.

The suffixes of the moods could not be placed in a distinct point of view without a detailed investigation. It may be sufficient to point out that *to* is distinctly observable as a suffix in one portion of the Latin imperative. That the suffixes of the potential, subjunctive, and optative moods, in the Greek and Latin, were originally distinct words, and perhaps verbs, like our own *may*, *can*, &c., is probable from general principles, and is confirmed by the appearance of the separate particles *ken*, *ke*, *an*, in the Greek language, which are used to denote a sort of potential mood, and bear a marked resemblance to our own *can*.

The last suffix for consideration is that which denotes the *voice*. The Greek grammarians acknowledge a middle or reflective voice; but the Latin language in fact possesses the same, as, for instance, in *accingo-r*, "I gird myself for the contest;" *nito-r*, "I support myself;" *lavo-r*, "I wash myself," "I bathe." And in both languages the middle voice is the parent of the passive. This may be illustrated by such phrases as the French *les bas se vendent ici*, "stockings sell themselves here," that is, "are sold;" the Italian *si dice*, "it is said," strictly *it says itself*. Now, the suffix of the Latin passive appears in the various forms *ur*, as *monet-ur*, *er* as *moneri-er*, *r* as *moneo-r*; but the attentive Latin student is ever ready to suspect when he meets with an *r*, that an older form of the word contained an *s*; and in fact we find an *s* in the form *moner-is*, where, moreover, the first part *moner* is another example of the corruption in question, for it supplies the place of *mones*. If, then, *s* is the original consonant of this suffix, we are forthwith directed to the reflective pronoun *se*; nor ought we to be stopped by the fact that this pronoun in Latin is confined to the third person. In the Russian and other Sclavonic languages, still more in the Lithuanian, the connection of all which with the Teutonic languages and with those of Greece and Rome is indisputable, the reflective pronoun, containing in fact the very same root as *se*, is applicable alike to all the persons; and indeed there was nothing in the nature of things to limit the Latin pronoun as to *person*, when it is confessedly unlimited as to *gender* and *number*.

The division of verbs into several conjugations depends upon the last vowel or consonant of the verb in its simple or crude state. Thus, in the Latin language, all verbs ending in *a* are said to be of the first conjugation, all that end in *e* of the second, those in a *consonant* or *u* of the third, and those in *i* of the fourth or last; for it accidentally happens that the Latin language possesses no verbs in *o*, except the fragmentary forms *gnovi*, *gnotus*, *potus*, *ægrotus*, which appear to imply the existence of stems in *o*, namely, *gno* (in English, "know"), *po* (compare the Greek *pe-po-ka*), *ægro*. The Greek language is not without a class of verbs having *o* for the final letter, as *doulo*, "enslave," &c. The division of verbs into conjugations is founded upon the fact that the union of the final letters in the crude form of the verb with the initial letters in the suffixes leads to changes dependent upon these letters. We will not enter here into the origin of these letters, *a*, *e*, *i*, as affixed to verbs. That they form no essential part of the root is clear, and a writer in the 'Transactions of the Philological Society' contends that they have all one common origin in a suffix *agh*, still found in the Gaelic languages with an iterative power, or what may perhaps be better expressed by the Latin *paulatim*. We will here merely note that such verbs are often called by grammarians *weak* verbs, in opposition to the simpler or strong verbs. As specimens of these, we may give the Latin *son-ere* (obsol.) and *sona-re*.

CONJUNCTIONS. Under this term grammarians commonly include several classes of words which have little similarity of meaning, and which, in their etymological origin, may be verbs, substantives, adjectives, or prepositions. The old definition of a conjunction, that it was a word which connected sentences together, will certainly not apply in all cases, if at least the word "and" is to be included. It is true, as Horne Tooke observes, that "the sentence 'You and I and Peter rode to London' may be resolved into three: 'You rode,' 'I rode,' 'Peter rode.' But try some other instances: 'two and two are four;' 'AB, BC, CA form a triangle;' 'John and Jane are a handsome couple.'—Does AB form a triangle?—Is John a couple?—Are two four?" ('Diversions of Purley,' Taylor's edition, i. p. 210.)

On the etymological origin of conjunctions, which is a distinct question from their use, some remarks will presently be made; in reference to their employment in the construction of a simple or compound sentence they may perhaps be divided into the following classes: 1. Conjunctions which unite either individual words, or phrases, or sentences, without, in the last case, implying any subordination of one sentence to the other. Such are the words: *and*, *or*, *nor*; or the double forms: *both—and—*, *either—or—*, *whether—or—*, *neither—nor—*. With respect to this class it may be useful to point out the great advantage which the Greek, and more particularly the Latin, language possessed in the variety of their forms for *and*: as *και*, *τε* in the former, *et*, *que*, *atque* or *ac* in the latter. This superiority over modern languages, simple as it is in itself, gave to the longest Latin sentence a perspicuity of arrangement, which in a great measure superseded the necessity for a cumbersome punctuation. ('Journal of Education,' vol. iv., p. 135.) 2. Conjunctions, which in themselves simply meaning *this*, being prefixed to a secondary sentence or phrase, direct the attention to that secondary phrase as a unit, and thus prepare it for subjection to some preceding word. This usage of the pronoun is as nearly as possible equivalent to the use of the bracket or vinculum in algebra, which connects the separate elements of any compound or polynomial term, and subjects it as a new unit to the algebraical operation, the sign of which is attached to the vinculum. Horne Tooke, in his remarks upon the so-called conjunction *that*, furnishes many examples: as, "I wish you to believe that I would not willingly hurt a fly," which is resolved by him into "I would not willingly hurt a fly; I wish you to believe *that*." A mathematician would have expressed it by "I wish you to believe [I would not willingly hurt a fly]," where the words within the brackets must be considered as a compound accusative or object after the verb *believe*. The Latin *ut* and *quod* in their origin are merely neuters of the relative, and the original meaning of the relative, it must be recollected, was *this*. [ARTICLE.] Hence they too are used in the same way as the English *that*; for example: *suadeo ut abeas*, "I recommend *this*, you should go away;" *lætatur quod redieris*, "he rejoices at *this*, you have returned." Other examples may be found in the use of the Greek *ὁτι*, which is again the neuter of a relative, as: *λεγω ὁτι τεθνηκε*, "I say *this*; he is dead." In Greek there is sometimes a double accusative after the verb, one of which simply denotes the object of the verb, and the other points to the condition or state of the object, as explained by the words that follow it: thus, *ὁρω σε ὁτι* κακως πασχεις, literally, "I see you *this* (that), you are suffering." This employment of the pronoun is more particularly to be noticed after prepositions. Thus, in the Latin language, if a simple noun be the object of a preposition, all that is required is to put that noun in a certain case, as *post cœnam*, "after dinner;" but if a verb with its accessories is to be subject to a preposition, it is common to interpose the vinculum *quam*, "this," as, *postquam cum fratre suo cœnaverat*, "after he had supped with his brother." Even in English we might say: "after that he had," &c. Examples of this usage are abundant in the forms *antequam, præterquam, extra quam, præter quod, prout;* and the word *this* is sometimes doubly expressed, as in *pro eo ut, ad-eo ut, propter-ea quod, ex eo quod, præter quam quod*. The German idiom agrees precisely with the Latin, as may be seen in *nach-dem, in-dem*, &c., as opposed to the employment of the simple prepositions *nach, in*, &c. The French, too, have their *pendant-que*, &c., *puis-que*, &c., and the English their *besides that*, &c., *now that*, &c., and the old phrase *being that*, &c. 3. The pronoun in the several languages thus employed as a vinculum is frequently attached as an enclitic to the preceding word, and grammarians, not observing the distinction between the governing word and the pronoun, have often given the name of conjunction to the compound, as *postquam* in Latin, διοτι in Greek, *puisque* in French, *nachdem* in German. 4. The vinculum, however, is not essential in those forms, and is therefore frequently omitted; but in case of this omission the governing word must immediately precede the phrase which is dependent upon it. This governing word, which expresses the nature of the connection between the subordinate and the superior sentence, is also called a conjunction, but here the term is used in a different sense. The words which signify *this*, of which we previously spoke, found their claims to the title of a conjunction upon the fact that they unite the several elements which follow into a whole. When the governing particle is so called, it is because it binds the one sentence to the other. 5. There is a class of words which correlate with conjunctions: such as *so* in connection with *as* or *that*, *yet* with *although*, *therefore* with *since* or *because*. These words are often called adverbs, but as they too serve to connect sentences, they deserve like the rest the name of conjunctions. They bear, in fact, the same relation to the other conjunctions that the so-called antecedent does to the relative. And that the antecedent and relative have the power of conjunctions is proved not merely by their use, but by their old and appropriate names, the postpositive and prepositive articles (*articuli*, that is, "little joints").

We have already said that conjunctions belong in their origin to all the leading parts of speech. Examples of verbs so employed are seen in the English *if*, formerly written *gif*, that is, *give*. (Horne Tooke, as before, p. 103, &c.) The Latin *licet*, "although," is evidently a verb signifying "it is allowed." So too *vel*, "or," appears to be an imperative of *volo*, "choose," but *si* "if," older form *sin*, instead of representing *sit*, as is often said, is of pronominal origin; and indeed akin to our own *so* and *such*, so far as regards the first element of this adjective (*so-lich*, German). The English *while* is a substantive signifying "time." "Either" and "whether" are of course pronominal adjectives, and "or" is a corruption from "other," as is evident from the German equivalent *oder*. And a similar analogy seems to lead to the derivation of the Latin *aut—aut*, from *alterum—alterum*. Conjunctions of a participial and prepositional character have occurred in the examples already quoted; but the relative form appears to be specially fertile in the production of this class of words, as, in the Latin, *quam, quando, quamquam, quamvis, ubi, unde, ut, quia, quod;* and the English *when, how, as, where*.

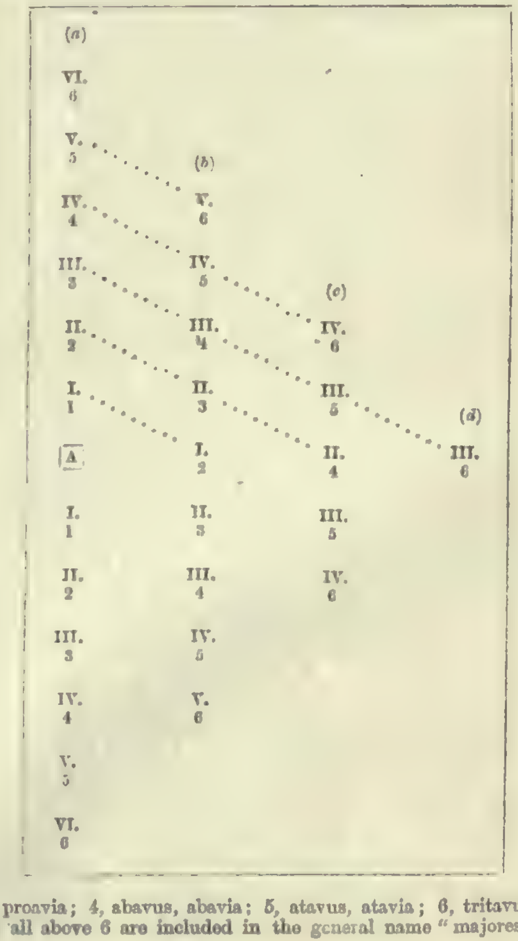
Many of the conjunctions defy all attempts at analysis, and certainly Horne Tooke, notwithstanding the acuteness and truth of his general views, has occasionally erred in the details of derivation.

CONOID (like a cone), a term sometimes applied, but in this country only, to the surface generated by the revolution of a conic section about its axis. [SPHEROID, HYPERBOLOID, PARABOLOID.]

CONSANGUINITY, or KINDRED, in law, is the relation subsisting between persons who are of the same blood, or, in other words, who are descended from the same stock or common ancestor. Consanguinity, in this sense, is either *lineal* or *collateral*. The former subsists between persons who are related to each other in the direct ascending line, as from son to father, grandfather, great-grandfather, &c.; or in the descending line, from great-grandfather to grandfather, father, and son. Collateral kindred are those who, though they have the same blood, derived from a common ancestor, and are therefore *consanguinei*, do not descend one from the other. Thus brothers have the same blood, and are descended from a common ancestor, but they are related to each other collaterally, and the children and descendants of each of them are all collateral kinsmen to each other. The canon law and the civil law have adopted different methods of computing the degrees of collateral consanguinity. According to the former, which has been followed by the law of England, we begin at the common ancestor, and reckon downward to the persons whose degree of consanguinity we desire to ascertain, counting each generation as a degree; and the degree of consanguinity in which they stand to each other is the degree in which both of them, or the more remote of them, stands to the common ancestor. Thus (to use the example given by Sir William Blackstone), Titius and his brother are related in the first degree, for from the father to each of them is counted only one; but Titius and his nephew are related in the second degree, for the nephew is two degrees removed from the common ancestor, namely, his own grandfather, the father of Titius. On the other hand, in this supposed case, the civilians would place Titius and his nephew in the third degree of consanguinity, for they count all the degrees from one given person upwards to the common ancestor, and downwards from that common ancestor, whose degree of relationship to the first person it is the object to establish. Thus they would count from Titius's nephew to his grandfather two degrees, and one more from the grandfather to Titius. By the law of England, all persons related to each other by consanguinity and affinity, nearer than the fourth degree of the civil law, are prohibited from marrying excepting in the ascending or descending line (in which the case is hardly possible by the course of nature); and by Stat. 5 & 6 Will. IV., c. 54, sec 2, it is enacted, "that all marriages celebrated after the date of that Act between persons within the prohibited degrees of affinity or consanguinity, shall be absolutely null and void to all intents and purposes whatsoever." Under the statute of distributions, 22 & 23 Car. II., c. 10, in making the distribution of an intestate's personal estate among the next of kin, the computation of degrees of kindred is according to the civil law. ('Novell.,' 118, and INTESTACY; Blackstone's 'Essay on Collateral Consanguinity,' and Blackstone's 'Commentaries,' vol. ii., p. 534; Mr. Kerr's ed.)

The question of consanguinity is the question of relation between two given persons, as explained above. If one of these persons i called $\boxed{\text{A}}$, all his lineal ancestors will be found in (*a*) the ascending line above him, and all his lineal descendants in the descending line below him. His collateral relations will be found in the parallel lines (*b*), (*c*), (*d*), &c. The Roman numerals denote the respective degrees of consanguinity in the canon, and the Arabic those in the civil law. Thus III. in the ascending line is A's great-grandfather, and III. in the descending line his great-grandson. In the ascending and descending lines the computations of the civil and canon laws, as already explained, is the same: in both laws the great-grandfather and great-grandson are respectively in the third degree from A. No. III. in line (*b*) is A's great uncle, who, according to the mode of reckoning already explained, is in the third degree of consanguinity to A by the canon law; and in the fourth, as denoted by the Arabic numeral 4, placed under III., by the civil or Roman law.

The following are the names for consanguinity in the Roman law. In line (*a*), ascending from A: 1, pater, mater; 2, avus, avia; 3, proavus, proavia; 4, abavus, abavia; 5, atavus, atavia; 6, tritavus, tritavia: all above 6 are included in the general name "majores." In



line (a), descending from A: 1, filius, filia; 2, nepos neptis; 3, pronepos, proneptis; 4, abnepos, abneptis; 5, atnepos, atneptis; 6, trinepos-trineptis: all below 6 are included in the general name of "posteri" or "posteriores."

In line (b), beginning with 2 and ascending: 2, frater, soror; 3, patruus, amita (uncle and aunt on the father's side); avunculus, matertera (ditto on the mother's); 4, patruus magnus, amita magna, avunculus magnus, matertera magna; 5, propatruus, proamita, proavunculus, promatertera; 6, abpatruus, abamita, abavunculus, abmatertera.

In line (b), beginning with 3 and descending, the names are, 3, fratris, sororis, filius et filia, and so on.

In (c), beginning with 4 and ascending: 4, consobrinus, consobrina, which are the general terms, but properly signify those born of two sisters (quasi consororini); sons born of two brothers are properly called fratres patrueles; daughters, sorores patrueles: 5, propior or prior sobrino, propior sobrina, the sons and daughters of the patruus magnus, amita magna, &c. (See Tacit. 'Annal.,' xii. 64.)

Some of the Latin writers used "nepos" to express a brother's or sister's son.

It is unnecessary to go farther. ('Institut.,' iii. tit. 6, 'De Grad. Cognationum.')

CONSCIENCE, COURTS OF. All the Courts of Conscience, Courts of Request, and other similar tribunals were abolished in 1846, by the statute 9 & 10 Vict. c. 95, on the creation of the new County Courts. [COUNTY COURTS.]

CONSCRIPTION is the name given to the mode of recruiting the French army. Under the old monarchy the army was recruited chiefly by voluntary enlistment, and the soldiers were taken mostly from the peasantry, by whom the change from the condition of a daily labourer to that of a soldier was considered as an improvement. The officers were appointed from among the higher or educated classes. When the revolution commenced the old army was broken up, the whole nation was called to arms, and volunteers were found in abundance. But as the soldiers were bound by no permanent obligation, a system of requisition was enforced, by which every district was bound to furnish a certain number of men for the regular army. But even this proved insufficient, and the Executive Directory found itself in want of soldiers to supply the numerous armies on the frontiers. In 1798, General Jourdan presented to the Council of Five Hundred a project of a law for a new mode of recruiting, under the name of conscription. This project was approved by the legislature, and passed into a law 5th of September, 1798. After setting down as a principle that every Frenchman is bound to defend his country when in danger, the law went on to say, that independently of danger to the country, every Frenchman from the age of twenty to twenty-five is liable to be called out to serve in the regular army. Every year lists were made in every department of the young men of the age above stated, divided into five classes, the first being those between twenty and twenty-one years; the second from twenty-one to twenty-two; and so forth. The number of men required for that year being made known by the government, and voted by the legislature, a distribution was made among the departments and districts of the quota which each was to furnish. The number required was then taken by lot from the first or junior class, and when that was exhausted from the second, and so on. This operation was repeated every year. The first levy by conscription in 1799 was 200,000 men. Bonaparte, when first consul, found the system already established, and he applied himself strenuously to render it more effective, and carry it to the utmost extent.

By an article of the Charte in 1830, a new law of conscription was provided. This law was promulgated 21st March, 1832, and it declares that the army is be recruited only by voluntary engagements and by the "appel," which term signifies a choice by the drawing of lots amongst the young men of each canton who have completed their twentieth year during the year preceding. The following persons are exempt from the "appel:" any orphan with younger brothers or sisters; an only son or grandson, and the oldest son or grandson of a widow or blind father, or of a father above sixty, but if the eldest son or grandson in either of the last-mentioned cases is blind or infirm, the youngest is exempted. There are also some other exceptions, as persons engaging in public instruction, or who are preparing for the Church or the ministry in any religious denomination which is paid by the state, also students who have obtained certain prizes. There is an appeal to a council of revision for those who conceive that they ought to have been exempted. The period of service is seven years. Persons who have drawn lots which render them liable to serve may obtain a substitute, who must be above twenty and not above thirty years of age, or thirty-five if he has already served in the army, or between eighteen and thirty if the brother of a person liable. Substitutes must not be married, or widowers with children. A person under the age of thirty cannot be admitted to any civil or military office unless he has fulfilled the obligations of the law of 21st March, 1832. Napoleon admitted in principle the procuring of substitutes, and even defended it in the Council of State, as necessary "in the present state of society, which was very different from that of Sparta or Rome;" but he afterwards surrounded it with so many difficulties, that substitutes became extremely scarce and expensive.

In Prussia, all men able to bear arms from twenty to twenty-five belong to the standing army; they serve three years, and are then discharged for two years, during which they are liable to be called out as the reserve. All those who have served in the standing army belong to the landwehr of the first ban, from the age of twenty-six to thirty-two inclusive. This ban, in time of war, is liable to serve abroad as well as at home. It is called out every year to exercise. The second ban is called out only in time of war, and includes all men capable of bearing arms till the age of thirty-nine. All older men fit for service belong to the landsturm. For an account of the Prussian military system, see Laing's 'Notes of a Traveller.' [MILITIA.]

CONSECRATION (*consecratio*), the act of sanctifying or making holy, consists in the solemn appropriation or dedication of anything to the service of the Deity. In modern times the consecration of men is usually called *ordination*, except in the case of kings and bishops, when the performance of the rites of sanctification is still named consecration. When applied to temples, churches, and altars, it is generally termed *dedication*. It is sufficient to advert to the religious antiquities of India, Egypt, Judæa, Chaldæa, Greece, Rome, and of the Celtic Druids in Britain and Europe in general, to show the antiquity of consecration. At the commencement of the Mosaic dispensation all the first-born of man and beast were consecrated to the Lord. (Exodus xiii. 2, 12, 15.) Subsequently the whole tribe of Levi was thus consecrated instead of the first-born (Numbers iii. 12, 45; viii. 16, 18); and Aaron and his sons, who were Levites, were more especially consecrated to the priest's office. (Exodus xl. 13.) The dedication or consecration of the tabernacle and altar is described in the book of Numbers, ch. vii. Of the dedication of the first or Solomon's Temple, a description is given in 1 Kings viii. 5; and of the second temple in Ezra vi. 16. Under the Jewish theocracy not only men and beasts were consecrated to the Lord, but houses, fields, and the walls of Jerusalem. (Leviticus xxvii.; Nehemiah xii. 27.) At the commencement of the 4th century, when Christianity, under Constantine, became the established religion of the Roman state, and Christian temples began to vie in magnificence with those of the Pagan deities, they were consecrated with great pomp; for instance, the church of Jerusalem, built by Constantine over the supposed site of the Holy Sepulchre, when the ceremony was performed by a full synod of all the bishops of the East. (Euseb. 'Eoc. Hist.,' l. 10, c. 45; Gratian. 'Concordantia Discordantium,' part 3.)

The following are the principal parts of the rite of consecrating a church according to the Roman Catholic pontifical: Previous to the ceremony three crosses are painted on each wall of the church, and over each cross is placed a lighted candle. The bishop, in his pontifical vestments, proceeds to the church door, attended by his clergy reciting the seven penitential psalms; and after a solemn procession round the external walls, which are copiously sprinkled, in the name of the Trinity, with a kind of brush dipped in consecrated water, the bishop knocks loudly at the door with his pastoral staff, repeating from the 24th Psalm, "Attollite portas, et introibit Rex Gloriæ;" to which a deacon, who is within the church, replies, "Quis est iste Rex Gloriæ?" The bishop responds, "Dominus fortis et potens, Dominus potens in prælio," &c.; then signing the door with the figure of the cross, he exclaims, "Ecce crucis signum! fugiant phantasmata cuncta." On the admission of the bishop and clergy the 'Veni Creator' is chanted, and ashes are strewn on the floor in the form of a cross, in which the bishop, with his staff, traces some alphabetical characters. After several prayers, the altar is consecrated by sprinkling it with a mixture of water, wine, salt, and ashes, in the name of Jesus Christ. The solemnity closes by depositing in the altar a vessel containing relics and incense, with a parchment inscribed with the name of the bishop and the date of the consecration. The church on this occasion is richly decorated, and the altar is illumined with a profusion of large tapers. (Broughton's 'Hist. Dic.,' vol. i., p. 311.) Churches are not recognised as such by the law of England until they are consecrated by a bishop. The form used by the Church of England is given at length in Bishop Gibson's 'Codex juris Ecclesiastici Anglicani,' pp. 1458-1463; see also Bishop Wilkins's 'Concilia Magnæ Britanniæ,' vol. iv., p. 668; and Burn's 'Eccles. Law, Churches,' sec. 2. The present form has been used since 1712; and in 1799 it was adopted, with some slight modification, by the Episcopal Church in America. One of the principal charges on which Archbishop Laud was arraigned before the Commons was, that he endeavoured to revive the Roman Catholic ceremonies in the consecration of churches and altars, with all their costly furniture. Still the Protestant form of consecration, as well as the Roman Catholic, is an imposing ceremony; and the 21 stat. Henry VIII. c. 13, states as the reason for allowing a bishop six chaplains, that this number is requisite for the consecrating of churches. The village feasts which are still celebrated in many parts of England commence on the anniversary day of the consecration of the parish church, and are said to have been substituted by Pope Gregory the Great for similar festivities appertaining to the Druidical religion. (Bingham, b. 8, c. 9.) Church-yards, when, as was usual, they adjoined the church, were consecrated at the same time; but since the establishment of cemeteries they are consecrated separately, and a part is left unconsecrated for the use of dissenters from the Church of England. Deacons and priests are likewise consecrated before entering on their holy office, and the form of their consecration, or ordination, as it is there called, is given in the Prayer Book. Consecration is generally understood to change not the nature of the thing consecrated, but merely the *use* of it; and in this opinion the Roman Catholics appear to acquiesce.

with regard to numerous objects which they usually consecrate, as church bells, candles, water, oil, crosses, pictures, &c.; but with respect to the consecration of the eucharistic bread and wine, they maintain that a complete change is effected in the thing consecrated.—the body and the blood of Jesus Christ, by the change of the bread into his body, and of the wine into his blood, being believed to be really present by virtue of the words of consecration. This is what is termed transubstantiation. (Brunet, 'Parallèle des Religions,' 4to, 1792, tome iii., p. 810; 'Exposition de la doctrine de l'Église Catholique,' par Bossuet.)

The consecration of animals was very common in ancient Egypt, where birds, beasts, and reptiles were privileged, as in modern India, to live unmolested, and even to receive adoration. Athenæus and Ælian speak of sacred fishes, adorned with necklaces; so the sacred crocodile in Egypt was decorated with ear-rings. (Herodotus, ii 69.) Consecration is a name given to the apotheosis of the Roman emperors, and coins and medals commemorating these events have the inscription "Consecratio." See an account of these funeral honours in the article Apotheosis, and the medal with the legend "Consecratio" in the article Aurelius, in Biog. Div.

CONSERVATORS OF THE PEACE, before the comparatively modern institution of justices of the peace, were officers who by the common law of England were appointed for the preservation of the public peace. These conservators, whose powers were far inferior to those of modern justices of the peace, consisting almost entirely of the authority to take sureties for the peace and for good behaviour, were of several kinds. In the first place, certain high functionaries were general conservators by virtue of their offices. Thus the king, the lord chancellor or lord keeper, the judges of the court of King's Bench, and the master of the rolls, were intrusted by the common law with the general conservancy of the peace throughout the realm, as incidental to their several offices. Other officers again were conservators only in special places; thus the judges of the common pleas and barons of the exchequer were conservators of the peace only within the precincts of their several courts. In like manner, judges of assize and gaol-delivery within the places limited by their commissions; coroners and sheriffs within their several counties, and constables and tithingmen within their hundreds or tithings, were all conservators of the peace at common law; and all the officers above enumerated retain their authority at the present day. But besides these official conservators, there were others who were expressly intrusted with the charge of the peace, either by prescription, election, or tenure. Thus it is said that the owner of a manor might have prescribed that he and his ancestors, whose estate he had, were entitled to be conservators of the peace within such manor. So also as sheriffs were formerly elected, and as coroners still are elected, by the freeholders of the county, certain persons were, before the reign of Edward III., elected conservators of the peace in different counties. There were also instances in which lands were granted by the king to hold of him by knight's service, and also by discharging the duties of conservation of the peace within the county where the lands lie. Besides these, there were conservators of the peace appointed by letters patent from the crown, in cases of emergency, to defend particular districts, where breaches of the peace were apprehended in consequence of foreign invasion or intestine tumult. All the different kinds of conservators of the peace above noticed, excepting those who have the duty cast upon them as incidental to other offices, were entirely superseded upon the establishment of the system of justices of the peace in the early part of the reign of Edward III. [Justices of the Peace.] (See also full details upon this subject in Lambard's *Eirenarcha*, book i., cap. 3.)

CONSERVATOR OF THE STAPLE, in the law of Scotland, an officer in the nature of a foreign consul, resident at Campvere, in the Netherlands. See the Act 1503, c. 81. The office has long been obsolete.

CONSERVATORY. The names given to the garden buildings employed for preserving plants in an artificial climate, are applied with so little precision, that it is almost a matter of indifference which to select for the purpose of explaining the principles that ought to be observed in the construction and management of such houses. We shall therefore reserve for the article Green-House what we have to say upon that head, and briefly dismiss the others as their names occur. In illustration of this remark we may observe that the term conservatory, which, as its meaning shows, was originally intended for buildings in which plants were preserved during winter, has come to be used, firstly for glass-houses in which plants are cultivated by growing them in the open border, and subsequently for all such glazed buildings whatsoever. A conservatory, properly so called, is a brick building heated by artificial means, having its whole southern part closed by large glazed sashes, which may be opened or shut at pleasure. Its floor is generally of stone, and a part of it is occupied by a stage on which plants in pots can be placed. One of these buildings, but in a ruinous state, may be seen in the physic garden at Chelsea; others are not uncommon in gardens that were laid out forty or fifty years ago, but they are fast falling into neglect and disuse—in our opinion undeservedly. Such a conservatory was intended to preserve during the winter orange-trees, myrtles, American aloes, and similar plants, which during the summer will flourish in the open air, but which require in winter to be protected against the inclemency, or, to speak more exactly, against the cold and wet of the English climate. Such plants are torpid during winter; their rest begins with that of our trees, and it is easy to prevent a renewal of their growth at too early a time; to preserve them against too much wet and from severe cold, especially in the spring, is all that is requisite for them, and these objects the old conservatory answered perfectly well. It had moreover the advantages of being spacious without being excessively costly; of being easily heated, and of requiring the smallest possible amount of labour for the plants preserved in it. Persons however, gradually forgetting the original object of a conservatory added to it numerous species requiring a very different treatment in winter from those it was contrived for; and what was far worse, they attempted by humidity and high temperature to keep the plants in a growing state through the winter. The necessary consequence of this was, that those plants which formerly succeeded in the conservatory became unhealthy, the new comers disappointed the expectations of their cultivators, and the class of building itself fell into discredit. The reason of this is sufficiently obvious. Plants when in a growing state require an abundant supply of light: a conservatory is particularly ill calculated, on account of its solid roof and sides, for the admission of light, and consequently a conservatory is not suitable for plants in a growing state; but plants when torpid, as in their winter season, require a very moderate supply of light, and this a true conservatory is sufficiently calculated to admit.

A house of this kind is best suited for gardens of considerable extent, where a large number of plants is required during the summer for the ornament of the flower garden and shrubbery. Under such circumstances we strongly recommend the erection of conservatories as the cheapest, the most efficient, and the most ornamental mode of preserving in a healthy state during winter not only oranges, myrtles, and similar plants, but in general all the species which are natives of countries that, without experiencing severe frost, are cold enough during winter to suspend the vital energies of vegetation. It will be perfectly within the gardener's power to keep the earth in which conservatory plants grow sufficiently damp during winter to enable them to accumulate by the return of spring an abundant supply of new sap; and this is all that he need be particularly reminded of, if he understands his business scientifically; if he does not, advice to him would be only a waste of words. [Green-House.]

CONSERVES differ from confections in minor details only. They are formed of flowers, herbs, roots, fruits, and seeds, all recent and fresh, beaten up with powdered sugar to the consistence of a stiff paste,—as a means of preserving the distinctive qualities of the plant in a fresh state. The range of substances thus treated is very extensive.

CONSIDERATION. This is a Latin word, *consideratio*, which, as well as the verb *considero*, was used by Cicero and others to express "careful observation," or "reflection," or "deliberation before action." It has nothing to do with looking at the stars, as the Latin grammarian Festus states; but it implies something which is nearer to the business of common life than star-gazing: it implies the sitting down of a man in a place alone or with others. The word *consideration* means "deliberation" in the English language of common life.

But the term consideration has also a legal and technical meaning, independently of its primary and common meaning; namely, the recompense which a party who enters into a contract gets for making, or the motive or inducement which he has to make, the contract in question; and such consideration may be either *express* or *implied*. The following are examples of *express* consideration: If a man agrees to sell his land to another for 100*l.*, the 100*l.* is the consideration for which he, the former, agrees to part with his land; or if a man promises to give 1000*l.* to another if he will marry his daughter, the fact of the latter marrying the daughter is the consideration for the agreement of the former to pay the 1000*l.* But there may be an *implied* consideration in many cases where none is expressed: for example, a man may undertake to do a piece of work for another without any express bargain that he shall be paid; but if he does the work according to his agreement, the other man may be compelled to pay him, because the law implies a promise on his part to pay if the work is done; and the implied consideration for this promise is the undertaking of the workman to do the work in question.

Contracts not under seal cannot be enforced if made without a consideration. A man may promise verbally or in writing to give another 1000*l.*; but the promise cannot be enforced unless there is a consideration for it; that is, some cause or reason which moved the contracting party to enter into the contract. But with regard to contracts under seal, the rule is different; for the law assumes such a contract to have been entered into with due deliberation, and binds the contractor to his engagement, whether he received a consideration for it or not.

Considerations are sometimes divided into *valuable* considerations and *good* considerations. Marriage is a valuable consideration; money, or any other thing which is of the nature of property, and has a common value, is a valuable consideration. If a man parts with his estate for a valuable consideration, the transaction is valid, and he who gets the estate has, so far as the consideration is concerned, a good title. A good consideration, on the other hand, is not sufficient to maintain the validity of a conveyance of property against the claim of a subsequent purchaser for a valuable consideration. Thus, if a man after his marriage settles an estate upon his wife and children in consideration of natural affection, and then sells the estate for money, the purchaser will have the estate, and not the wife and children (Hill *v.* Bishop of

Exeter, 2 Taunt. 69),—such a settlement after marriage being held to be voluntary or gratuitous. But a settlement of property made in consideration of a future marriage, which afterwards takes place, is a settlement for valuable consideration; and so is an actual settlement after marriage, if it is made pursuant to a written agreement entered into before marriage. But the distinction just pointed out between *good* and *valuable* considerations exists only in the case of contracts *under seal*. In the case of contracts *not under seal*, no consideration is good which is not also valuable.

So by the Statute 13 Eliz. c. 5, the object of which is to prevent persons from cheating their creditors by disposing of their real or personal property, it is declared that the provisions of the Act do not extend to estates or interests made or conveyed "upon good consideration and *bonâ fide*;" and the term good consideration here has been held to be equivalent to what has been above defined to be a valuable consideration.

The Acts 27 Eliz. c. 4, and 30 Eliz. c. 18, § 3, made void, as against subsequent purchasers, all conveyances, &c., of real property which are made for the purposes of defrauding such purchasers, unless "upon or for good consideration and *bonâ fide*." This statute has received a singular interpretation; for it has been decided that it makes void a previous conveyance, though not made to defraud any one, if the consideration is not such as the statute intends; and accordingly, as in the case just stated, if a man settles his land after marriage on his wife and children, and then sells it, the prior settlement is void as a fraudulent conveyance.

A voluntary conveyance by a man who is at the time insolvent is not valid against his creditors; but if a man is not insolvent at the time, a voluntary conveyance—that is, one where there is no valuable consideration—is valid against future creditors. (13 Eliz. c. 5.) A conveyance for valuable consideration, such as marriage, is a valid conveyance, even if a man be insolvent at the time. An insolvent may therefore cheat his creditors by settling his property on a woman with a view to marriage, and then marrying her; but in certain cases, such settlements are not valid against creditors when made by a person who is subject to the bankrupt laws. A voluntary conveyance is not valid against a future purchaser for good consideration: it is a fraudulent transaction according to the construction of the 27th of Eliz.; and as such is declared void against the purchaser. If the purchaser knew that there was such a voluntary prior conveyance, that makes no difference; his purchase is valid against such conveyance.

It appears from these instances that the fact of there being a good consideration may be evidence that there is no fraud; and that the absence of it may raise a presumption of fraud.

Every deed, therefore, or instrument by which property is conveyed to another, ought to show some consideration for which the person conveys such property; for though a deed is valid between the parties to it when no consideration is expressed, it may be invalid with respect to other persons who are not parties to it.

There is no absolute amount of consideration which can be legally required; but if the amount were very small, this might in some cases raise a presumption of fraud; although, even if the amount of consideration should be the full value of the thing conveyed, it might be necessary in some cases to inquire whether the consideration expressed was actually paid.

In the case of a contract or agreement to give or settle property, the necessity for a consideration is obvious, both for the protection of the giver, and of others to whom he is indebted, or whom it is his moral duty to provide for. No such contract can be enforced unless it be made as a sufficient legal consideration. An agreement to settle property on a lawful child may be such consideration; the case of an illegitimate child is not such a consideration. An illegitimate child is viewed as standing to his supposed father exactly in the situation of a stranger.

Many curious legal questions have arisen on the doctrine of consideration, as, for instance, in the case of one man promising to pay the debt of another. But the rule is, that a promise to pay a debt already incurred by another is not binding, unless it be made on some consideration:—for example, the agreement by the creditor to forbear proceedings against the debtor to recover it; or unless such debt was originally incurred at the request of the party making such promise.

Of course any contract made in consideration of the doing of a fraudulent or illegal act, is void.

CONSISTORY is the court christian, or spiritual court, formerly held in the nave of the cathedral church, or in some chapel aisle or portico belonging to it, in which the bishop presided, and had some of his clergy for assessors and assistants. But this court is now held by the bishop's chancellor or commissary, and by archdeacons and their officials, either in the cathedral church or other convenient place in the diocese, for the hearing and determining of matters of ecclesiastical cognisance happening within that diocese.

By stat. 24 Henry VIII. c. 12, an appeal lies from this court to the court of the archbishop of the province; but as proceedings against the beneficed clergy now take place under the Church Discipline Act, 3 & 4 Vict. c. 86, and against curates under stat. 1 & 2 Vict. c. 106, and proceedings against laymen are almost unknown, the functions of the consistory court are rarely called into action.

CONSOLS, a term familiarly used to denote a considerable portion of the public debt of the United Kingdom, more correctly known as the three per cent. consolidated annuities. This portion of the debt originated under an Act 25 Geo. II., whereby various perpetual and lottery annuities then outstanding, and which from the time of their creation had respectively borne an interest of 3 per cent., were brought under one head in the public accounts. Various additions have from time to time been made to the amount of these annuities; and, on the other hand, some diminution has been effected by the operation of the sinking-fund and the application of surplus revenue. The capital outstanding and unredeemed under this head, on the 5th of January, 1859, amounted to 407,202,855*l.*, of which 6,373,044*l.* was on account of the Irish debt. The whole bears an interest of 3 per cent. per annum.

CONSONANCE, in Music, a term which has, we think, often been explained with too strict a regard to its etymological meaning. That it signifies *one sound heard with another* is undeniable, but the two sounds must, in our opinion, be concords. [CONCORD.] *Consonance* and *dissonance* are words which, in music, ought to be considered as synonyms of *concord* and *discord*.

CONSONANT. [ALPHABET.]

CONSPIRACY. Every conspiracy to do an unlawful act which is injurious to individuals or to the public, is a misdemeanor at the common law of England. Many frauds affecting individuals, which cannot be made the subject of prosecution as such, become indictable when they are effected by the co-operation of several confederates. Thus, where several persons agree by indirect means to impoverish a third person, as by circulating calumnies injurious to his character or credit, the offence is punishable as a conspiracy, though the concerted acts alone, when committed by individuals, could only have formed the subject of a civil action by the injured party. Another instance of this is, the case of a conspiracy among journeymen or servants to raise the price of wages, by molesting those who work under a certain price. In former times, persons convicted of conspiracy at the suit of the king (the nature of which offence is very doubtful), were liable to receive what was called *villainous* judgment, by which they were rendered incapable of acting as jurors or witnesses, their lands and goods were forfeited for life, and their bodies committed to prison. This judgment was never however inflicted upon persons convicted of conspiracies of a less aggravated kind at the suit of the party; and in modern times, the villainous judgment having become obsolete by long disuse, the punishment of conspiracy has been by fine, imprisonment, and sureties for good behaviour, at the discretion of the court. (Russell *on Crimes and Misdemeanors*, vol. ii.)

CONSTABLE. This word is supposed by Ducange, Spelman, Cowell, and other legal etymologists, to be corrupted from *comes stabuli*, which was another name for the *tribunus stabuli* or *prepositus equorum*, a kind of master of the horse, frequently mentioned as an officer of state in the middle ages. (See Ducange's 'Glossary,' *ad vocem* 'Comes Stabuli.') Sir Edward Coke, Selden, and several other writers, insist upon another etymology—from two Saxon words, *koning*, a king, and *stapel* or *stabel*, a stay or support—*quasi columen regis*. Both these derivations are equally remote from the description of the office of our modern constable; but the former appears to be far the more probable; and in accordance with it, the constable of France was an important officer of the highest rank in that country, who had the chief command of the army, and had judicial cognisance of military offences; and whose duty it was to regulate all matters of chivalry, such as tilts, tournaments, and feats of arms. This office was suppressed in France by an edict in the year 1607; it was revived by Napoleon, and constituted one of the six grand dignities under the French empire; and was finally abolished upon the restoration of the Bourbon dynasty in 1814.

Immediately after the Norman conquest, we find in England an officer of the crown called the Lord High Constable, whose duties, powers, and jurisdiction were in most respects strictly analogous to those of the constable of France. The office was one of great dignity and power, both in war and peace, the constable having the command of the army and the regulation of all military affairs. He was the supreme judge of the court of chivalry, in which character his encroachments upon other courts were so heavy a grievance in early times, that the stat. 13 Rich. II. c. 2, was passed to restrict his jurisdiction to "contracts and deeds of arms and things which touch war, and which cannot be discussed or determined by the common law." The office for several centuries after the Conquest, passed by inheritance in the line of the Bohuns, Earls of Hereford and Essex, and afterwards in the line of their heirs-general, the Staffords, Dukes of Buckingham, in right of certain manors held by them by the feudal service of being constables of England. The fees of the office were extremely burdensome to the crown; and the possession by a subject of the hereditary right to command the militia of the realm, independently of any royal appointment, was an unusual and frequently a dangerous power; and on this account Henry VIII., in the early part of his reign (1514), consulted the judges respecting the means of abolishing the tenure. He was advised by them, that as the individuals holding the manors were only compellable to exercise the office *ad voluntatem regis*, he had the power of discharging the feudal service altogether; and acting upon this opinion, the king abolished the office, by disclaiming to have the services any longer executed. (See Dyer's 'Reports,' p. 282 b.) The effect of this was, that Edward Stafford, the last Duke of Buckingham in that line, the hereditary high constable of England at the time of this resolution, held the manors after this period discharged of the service of being constable. All doubt which might have been suggested respecting the legal extinction of the office by this means, was removed eight years afterwards by the attainder of the Duke of Buckingham for high treason, upon which event the manors in question were forfeited to the crown. Since that time, the office of high constable has never been granted to any subject excepting *pro hâc vice*, upon great and solemn occasions, such as the king's coronation or trials of peers.

"Out of this high office," says Lambard, in his 'Duties of Constables,' "the lower constableship was first drawn and fetched, and is (as it were) a verie finger of that hand; for the statute of Winchester, which was made in the time of Edward I., and by which the lower constables of hundreds and franchises were first ordained, doth, among other things, appoint that, for the better keeping of the peace, two constables in every hundred and franchise should make the view of armour." He then concludes, in justification of his etymology of the term, that "the name of a constable in a hundred or franchise doth mean that he is an officer that supporteth the king's majesty in the maintenance of his peace." This derivation of the office of a common constable seems very improbable, especially as it is the better opinion that these officers were known to the common law before the statute of Winchester. (See Hawkins's 'Pleas of the Crown, book ii. cap. 10.) An ancient judicial authority, chief justice Fineux, in the reign of Henry VII., gives a more reasonable account of the matter. He says that when the superintendence of the peace of a county was found too great a task for the sheriff, hundreds were formed, and a conservator of the peace under the sheriff appointed in each, who was called a constable. This was the high constable, or constable of the hundred. In process of time, as population increased and towns grew into existence, it was found expedient to make a further subdivision for the preservation of the peace; and accordingly, conservators were appointed for manors, vills, and tithings, who were then called petty constables. (See 'Year Book,' 12 Henry VII., pl. 18.)

Following this account of their origin, which is confirmed by many of the minute incidents of the two offices, constables, in the usual acceptation of the term at the present day, are of two kinds; constables of hundreds, who are still called high constables, and constables of vills or tithings, who are called either petty constables or tithingmen. Both high and petty constables were formerly chosen by the jury at the court leet, and were sworn in and admitted there by the lord or his steward; but afterwards the high constables were usually chosen by the magistrates at the quarter-sessions, and now, under the 7 & 8 Vict. c. 33, by the justices at special sessions of the division held for hearing appeals from the parish rates.

The petty or parish constables who had been from ancient times appointed to their office yearly by the court leet, are now, by virtue of the 5 & 6 Vict., c. 109, amended by the 7 & 8 Vict., c. 52, and the 13 Vict., c. 20, appointed by the justices at special sessions held for the purpose yearly, between the 24th of March and the 9th of April, from lists prepared by the overseers of each parish, of persons qualified to serve; but the choice of the justices is not restricted to such lists, and their appointment is valid if it be of a person duly qualified, though his name is not on the overseers' list. The qualification includes every "able bodied man resident within the parish, between the ages of 25 and 55 years, rated to the relief of the poor, or to the county rate, on any tenements of the nett yearly value of 4*l*. or upwards;" but this is subject to a very numerous list of exemptions given in the act, and also to the disqualification of all licensed victuallers, and persons licensed to deal in any exciseable liquor, or to sell beer by retail, or gamekeepers, and all persons who have been attainted of any treason or felony, or convicted of any infamous crime.

But the insufficiency of the ancient means of police coming to be increasingly felt, as modern society advanced in civilisation, Sir Robert Peel, when Secretary of State for the Home Department, in 1829, was enabled by parliament under the 10 Geo. IV., c. 44, amended by the 2 & 3 Vict., c. 47, to establish the metropolitan police force, under the regulation of two salaried justices or commissioners, to whom is entrusted, subject to the approbation of the Secretary of State, the appointment, control, and regulation of the police of the metropolitan district. This was followed by the Municipal Corporations Act (5 & 6 Will. IV., c. 76), which provided, sec. 76, for the appointment of constables by the Watch Committee, to keep the peace within the cities and boroughs of England and Wales. Many large towns and cities, including the city of London, have their police appointed and regulated under local statutes, obtained for the purpose, and many others have availed themselves of the general powers contained in the Town Police Clauses Act, 1847, the 10 & 11 Vict., c. 89. As the same sense of insecurity gradually expanded into the rural districts of the country, provision came to be made by the 2 & 3 Vict. c. 93, and the 3 & 4 Vict., c 88, for the appointment of additional constables for counties or districts of counties, in accordance with the report of justices in quarter sessions, or sessions of the liberty, to the Secretary of State, respecting the necessity and number of such constables in the district or county. But this power was used so sparingly by the country justices, and burglaries and crimes with violence became so frequent in the neglected districts, that parliament, by the 19 & 20 Vict., c. 69, made it compulsory on the justices at the general or quarter sessions, next after the 1st of December, 1856, to establish a sufficient police force in every county or residue of a county, where no such sufficient force existed when the statute was made. The statute provides for annual returns connected with the state of crime in the country, and for a contribution from the consolidated fund, of one-fourth of the expense for pay and clothing of the police of counties and boroughs, established under that or the two previous acts already mentioned, if such force is approved as efficient by the Secretary of State.

Besides the constables and police already mentioned, two or more justices of the peace, upon information that disturbances exist or are apprehended, are authorised by the 1 & 2 Will. IV., c. 41, amended by the 5 & 6 Will. IV., c. 43, to appoint special constables; and by the 83rd section of the Municipal Reform Act, magistrates in boroughs are authorised to swear in as many inhabitants as they think fit, to act as special constables when called upon.

With regard to the powers and duties of these officers, it is enacted by the Metropolitan Police Act and the Municipal Reform Act that the constables to be appointed under those statutes respectively "shall have all such powers and privileges, and be liable to all such duties and responsibilities, as any constable has within his constablewick by virtue of the common law of this realm;" and hence it becomes of great practical importance to ascertain with precision the common-law incidents of the office of constable.

1. By the common law constables are said to have been conservators of the peace; and in consequence of this character probably every constable has undoubted authority to arrest all persons who commit an affray, assault, or breach of the peace *in his presence*, and keep them in safe custody until they can be brought before a magistrate. It is said also by ancient authorities, that by virtue of his power as a conservator of the peace, he may himself, on view of a breach of the peace, take surety of the peace by *bond*, though he cannot do so by recognisance, being incompetent to administer an oath. But as his duty is to preserve the peace, and not to punish for the breach of it, it is doubtful whether he can arrest by his own authority and without a warrant, upon the information or charge of a third person, for an affray committed in his absence. (See the case of 'Timothy *v.* Simpson,' 1 Crompton, Meeson, and Roscoe's 'Reports,' p. 760.) By sect. 9 of the Metropolis Police Act, and by sect. 79 of the Municipal Corporation Reform Act, and sect. 8 of the Rural Police Act, the 2 & 3 Vict. c. 93, constables appointed under those Acts are expressly authorised, in charges of petty misdemeanour in the night-time, to take bail by recognisance for the appearance of the offender before a magistrate within a limited time.

2. A constable having reasonable cause to suspect that a felony has been committed, may arrest and detain the supposed offender until he can be brought before a magistrate to have his conduct investigated; and he will be justified in so doing, even though it should afterwards appear that in fact no felony was committed. In this case there is a distinction between the authority of a constable and that of a private person; the former may arrest if he can show a reasonable ground of suspicion that a felony has been committed; but a private person, in order to justify himself for causing the imprisonment of another, must prove, in addition to the reasonable suspicion of the individual, that a felony has actually been committed. A constable is bound to arrest any person whom he sees committing a felony, or any person whom another positively charges with having committed a felony; but, generally speaking, he has no authority to arrest for a misdemeanour, either upon his own reasonable suspicion or the charge of another person, without a magistrate's warrant. With respect to the authority of a constable to arrest for felony or breach of the peace, Mr. Justice Buller is reported to have said, that "if a peace-officer, of his own head, takes a person into custody on suspicion, he must prove that such a crime was committed; but if he receives a person into custody on a charge preferred by another of felony or breach of the peace, then he is to be considered as a mere conduit; and if no felony or breach of the peace was committed, the person who preferred the charge alone is answerable." Lord Ellenborough (in the case of 'Hobbs *v.* Branscomb,' 3 Campbell's 'Reports,' 420), said that "this rule appeared to be reasonable."

3. Constables were authorised by the common law to arrest such "strange persons as do walk abroad in the night-season." (See Lambard, 'Constable,' p. 12.) This authority, which was perhaps sufficiently definite in times when the curfew was in practice and watch and ward were being kept, is at the present day of so vague a nature, that a peace-officer could scarcely act under it without imminent danger of an action in every particular instance. It is, however, obviously essential to the efficiency of any system of police, that constables should be armed with some general authority of this nature, especially in towns. By the 7th section of the Metropolitan Police Act, it is provided that "any man belonging to the police force appointed under that Act may apprehend all loose, idle, and disorderly persons whom he shall find disturbing the public peace, or whom he shall have just cause to suspect of any evil designs, and all persons whom he shall find between sunset and the hour of eight in the forenoon lying in any highway, yard, or other place, or loitering therein, and not giving a satisfactory account of themselves, and deliver them to the constable in attendance at the nearest watch-house, to be secured until

they can be brought before a magistrate." The Municipal Corporations Act contains a similar but less comprehensive provision, authorising "any constable appointed under that Act, while on duty, to apprehend all idle and disorderly persons within the borough whom he shall find disturbing the public peace, or whom he shall have just cause to suspect of intention to commit a felony." Besides these specific authorities, however, which apply only to the metropolitan police district and the boroughs affected by the Municipal Corporations Act, there is no doubt that in general a constable, by virtue of his common-law authority, may stop any person carrying by night a bundle or goods under circumstances of reasonable suspicion; and if, upon examining him, his suspicions are not removed, he may detain him in his custody. A constable has also a general authority to apprehend for offences against the Vagrant Act, 4 & 5 Geo. IV., c. 83, or against the Larceny Act or the Malicious Injuries Act, 7 & 8 Geo. IV., c. 29 and 30.

4. In the execution of a warrant a constable acts no longer as a conservator of the peace, but as a ministerial officer to the magistrate who signs it. He is the proper officer to a justice of the peace, and is bound by law to execute his warrants, and may be indicted for disobeying them. It is his duty to execute the warrant of a magistrate as soon as it comes to his hands; and where he arrests or distrains, or does any other act within his precinct, though it is not absolutely necessary by law that he should show his warrant, he ought always to give notice of it, and he will be wise to produce it in all cases where it is demanded. If, however, he act out of his precinct, or be not sworn and commonly known, he must show his warrant if demanded; but as the warrant constitutes his justification, he is not required to part with it out of his possession. If the constable has a legal warrant to arrest for felony, or even breach of the peace, he may break open doors after having demanded admittance and given notice of his warrant; and if, after such notice, he is resisted and killed, it will be murder. If a warrant be directed to a constable by his name of office merely, he is *authorised* by the 5 Geo. IV., c. 18, to the same extent as when the warrant is addressed to him by his own personal name, to execute it out of his own constablewick, provided it be within the jurisdiction of the magistrate who signs it; but he is not *bound* to do so, and may in all cases make his election whether he will go beyond his own precincts or not.

5. The law has made several provisions for the indemnity and protection of constables in the proper discharge of their duty. Thus by the Stat. 7 Jac. I., c. 5, if an action be brought against a constable for anything done by virtue of his office, he may plead the general issue and give the special matter in evidence; and if he recovers, he is entitled, by the 5 & 6 Vict., c. 97, to full costs. Formerly if a magistrate granted a warrant in a matter over which he had no jurisdiction, the officer who executed it was liable to an action of trespass for so doing; but by the 24 Geo. II., c. 44, s. 6, it is enacted that no action shall be brought against any constable for anything done in obedience to the warrant of a justice of the peace, unless he has neglected or refused to show his warrant on being required so to do. And if, after he has shown his warrant, any action is brought against the constable alone, without joining the justice who signed the warrant, the defendant, on producing the warrant at the trial, is entitled to a verdict, notwithstanding the defect of the justice's jurisdiction; and if the action be brought against the constable jointly with the justice, the constable is entitled to a verdict on proof of the warrant. By the 8th sect. of the same statute, all actions against constables for anything done in the execution of their office must be brought within six months. For the further protection of constables, the stat. 9 Geo. IV. c. 31, s. 25, enacts that persons convicted of assaults upon peace-officers in the due execution of their duty may be imprisoned with hard labour for two years, and be fined or required to find sureties for keeping the peace.

For the guidance of the metropolitan police force, the commissioners deliver to each of the men printed directions, which contain an accurate and perspicuous summary of the laws relating to the duties, liabilities, and indemnities of constables. In those boroughs which have adopted a new system of police under the Municipal Corporations Act, similar codes of instruction have been issued to the constables. (For fuller information upon the whole of this subject, see Viner's 'Abridgment,' Bacon's 'Abridgment,' Burn's 'Justice,' title 'Constable,' and Blackstone's 'Commentaries,' by R. M. Kerr, LL.D., vol. i.)

CONSTABLE, LORD HIGH, OF SCOTLAND. In the 12th century we find the office in possession of Hugh de Morvill, of the family of the De Morvilles, barons of Burgh, co. Cumberland, contemporary with one Edward, Conestabulus; himself constable of Scotland, and the possessor of vast estates in Teviotdale, Lauderdale, Lothian, Clydesdale, and Cuninghame. He died in 1162, and the office was enjoyed by his descendants till it came to John Comyn, earl of Buchan, who was deprived of it in the year 1308 for his adherence to the Baliol interest. Sir Gilbert de Hay, of Errol, was then made constable of Scotland during pleasure; and in 1311 the office was bestowed on David de Strathbogie, earl of Athol, in like manner during pleasure; but he being soon afterwards outlawed for espousing the cause of Baliol, Sir Gilbert de Hay, before mentioned, got the office in fee and heritage in the year 1314; since which time the constable's staff, then put into his hands by Bruce, has remained in the Errol family.

The office and jurisdiction of the lord high constable of Scotland differ from those of the like officer in England. No formal distribution of the powers of the lord justiciar of Scotland, such as took place at the breaking up of the aula regis of England, was ever made in the former kingdom; nor when in the course of years this happened, did the once large powers of the justiciar pass to the like officers in the one country as in the other. On the new modelling of the judicial polity of England by King Edward I., the constable and mareschal were set over a court of chivalry, with jurisdiction in matters of honour and arms. But in these, the constable of Scotland never had jurisdiction. His jurisdiction was of the nature of that in England, vested by 33 Henry VIII. c. 12, in the lord steward of the king's household, or (in his absence) of the treasurer, comptroller, and steward of the marshalsea; for according to the Leges Malc. II., he judged jointly with the mareschal in all transgressions committed within certain limits of the king's court. But even this jurisdiction seems to have been exercised in fact by the lord justiciar; the constable only protesting against the interference with his powers. In the reign of King Charles I. a commission was issued to inquire into the nature and extent of the constable's jurisdiction; and they reported that it extended to all slaughters and riots committed within four miles of the king's person, or of the parliament or privy council. No alteration was made at the Union; and by the act 20 Geo. II. c 43—which swept away so many other heritable jurisdictions—the office and jurisdiction of the lord high constable of Scotland were expressly reserved.

CONSTANCE, COUNCIL OF. [COUNCILS OF THE CHURCH.]

CONSTANT, a quantity which remains the same throughout a problem. Thus in the question, required that point of a circle which is at a given distance from a given straight line, the radius of the circle is a constant. If the problem require the use of twenty different points of the circle, the radius is the same for all.

A constant may be determinate, or it may be indeterminate or arbitrary. Thus the proportion between the circumference and diameter of a circle is a determinate constant, being 355 to 113 very nearly; but in the problem, required the relation which exists between the abscissa and ordinate of a circle, the radius of that circle is an arbitrary constant.

The term constant is frequently applied to any remarkable or very necessary number which enters a question, as follows: By the *constant* of aberration is meant that one constant by the determination of which the aberration is obtained from its known laws at any given time; in this case it is the maximum aberration, or about 20½″. [ABERRATION.] Thus we have the constant of nutation, the constant of friction, &c.

Nothing is more common in mathematical works than the term *variation of constants*, which appears a contradiction. But its meaning is as follows: A quantity which upon one supposition would remain constant, becomes variable by the introduction of another supposition. Thus, taking into account the earth's attraction only, the longitude of the moon's node is constant; but by the attraction of the sun and planets, its place is slowly changed. In this case one of the constants is said to vary.

CONSTELLATION (a putting together of stars), the name of one of those groups of stars into which the whole heavens are divided, and to each of which is imagined to belong the figure of a man, an animal, or some other object, natural or artificial.

The history of the constellations is a matter of mythological antiquity, the most curious features of which are connected with the twelve signs or constellations of the ZODIAC, or the sun's apparent yearly track. It is sufficient for us here to say, that it is certain we derive our constellations for the most part from the Greeks, and that it is nearly as certain that they derived them from the East, though it is highly probable that they altered the legends to suit their own mythology, and in some instances even the figures. Their firmament, if it confined itself to recording the vast and striking events of their mythic system, as in Argo or Hercules, might bear an external presumption of originality, which it wants altogether while so prominent a constellation as the Great Bear represents nothing but the unimportant and irrelevant story of Callisto. But while we are just in possession of sufficient knowledge to deny the original formation of the constellations to the Greeks, and perhaps even to the Egyptians, we have not enough to say in what nation they were first constructed.

The method of figuring the constellations, though in many instances it gives groups which are striking to the naked eye, is one of the worst which could have been invented for the modern purposes of astronomy. A dragon winding round three-quarters of the globe, and a man extending his arms and legs between half a dozen other figures, cannot connect their included stars in any manner which will lead to useful combinations. So that in our modern catalogues, though λ Draconis and ζ Draconis are said to be in the same constellation, the connection is purely one of names, and suggests no ideas of relative position. There are even instances in which stars bearing the name of one constellation are situated in another.

We shall proceed to describe the methods by which the stars in a constellation are distinguished, and the plan we have adopted in the present work. The letters of Bayer are generally adopted for all the stars in his maps. The stars were ranged by him in order of brilliancy, as they appeared to the naked eye, about the year 1600. The Greek letters were first used, and afterwards the Italic small letters. Thus, α is the most brilliant star in a constellation according to Bayer, while *p*, *q*, &c.,

are comparatively faint. Other astronomers have since carried on the lettering of Bayer, and we have latterly (in this work) distinguished the letters added since Bayer's time by parentheses in all those constellations which were partly lettered by Bayer and partly by others. But in all cases the extent of Bayer's letters may be ascertained by reference to the article in the BIOG. DIV. headed by his name. The letters had been adopted, however, previously to Bayer. [PICCOLOMINI, in BIOG. DIV.]

The next step in the arrangement was that of Flamsteed, who retained the old method of describing stars by their situation in the figure of the constellation (as in the leg, in the head, &c.), but placed the stars of each constellation in order of right ascension, or in the order in which they come on the meridian. Succeeding astronomers described each star by the number which it stood from the beginning in the constellation, and called it Flamsteed's number. Thus 7 Draconis means that star of Draco which comes on the meridian the seventh of all the stars observed by Flamsteed in that constellation. Mr. Baily, in his new edition of the British Catalogue, introduced new stars from Flamsteed's papers, but has allowed them to stand without disturbing the established numbering, and they are easily identified by the general numbering of the new catalogue. Thus, there is a star in Capricornus between 12 Capr. and 13 Capr., which may be described as 2786 of Mr. Baily's edition, that is, the 2786th from the equinox of 1690 of *all* the stars observed by Flamsteed, both of those which are in the 'British Catalogue' of A.D. 1725, and those which have been since drawn from Flamsteed's papers.

The numbering of Piazzi is on a different and inferior principle. The whole heavens being divided into twenty-four hours of right ascension, the stars are numbered in their respective hours of right ascension. For instance, (303) Can. Maj. is, according to Piazzi, a star in Canis Major, not the 303rd of that constellation, but the 303rd of the hour of right ascension in which it fell in the year 1800, counting the first star of the catalogue which passed after the sidereal clock had marked the hour as 1, the second star as 2, &c., and affixing to each the name of the constellation in which it is. If the equinox were fixed, this method would be a good first correction of the vagaries of the constellations; but as it is, some stars which were in one hour of right ascension when Piazzi formed his catalogue are now in another, such as 12 Cancri, 15 Argus, &c., which were in 1830 on the borders of the 7-8 hour of right ascension.

In most other catalogues, such as those of Bradley, Lacaille, Mayer, Fallows, &c., the stars are usually numbered in their order from the beginning of the catalogue, the order being that of right ascension.

The recognised makers of constellations are Aratus, Ptolemy, Bayer, Hevelius, and Lacaille. But Tycho Brahé, Lemonnier, and Poczobut have each added one constellation in the following list, and Halley two. The names without any letter are all in Aratus. (Remember, however, that Libra is only the *claws* of the Scorpion, both in Aratus and Ptolemy.) [LIBRA.] Three additional ones in Ptolemy's Catalogue are denoted by P.: Bayer's by B.; Hevelius's by H.; Lacaille's by L.; Tycho Brahé's by T.; Halley's by Ha.; Lemonnier's by Le.; and Poczobut's by Po.

There are many other constellations formed by different individuals; but these are not now generally admitted. Such are the Antinous of Tycho Brahé; the Mons Mænalus and Cerberus of Hevelius; the Oak of Charles II. and the Cor Caroli of Halley; the Table Mountain and the Nubecula Major and Minor of Lacaille (the latter being not clusters of distinct stars, but large nebulæ); the Reindeer of Lemonnier; the Reaper of Lalande; the Honours of Frederic, the Sceptre of Brandenburgh, Herschel's Telescope, the Balloon, the Mural Quadrant, the Cat, and the Log Line of Bode; and George's Harp of Hell. Many others, we believe, have been proposed, but there would be little use in reviving their names. In fact, half a century ago, no astronomer seemed comfortable in his position till he had ornamented some little cluster of stars of his own picking with a name of his own making.

In the large maps of the stars, published by the Society for the Diffusion of Useful Knowledge, the constellations are figured precisely as described by Ptolemy, and the additional ones are not drawn, which will therefore render them useful to the readers of Greek astronomical works.

CONSTIPATION, an undue retention or an imperfect evacuation of the fæces. The alimentary canal, considered physiologically, may be divided into two portions; one appropriated to the conversion of the aliment into nutriment, and the other appropriated, among other functions, to the separation and discharge of the refuse matter of the aliment. The first constitutes the apparatus of digestion, and the second that of fæcation. Independently of the organs appropriated to the performance of the preparatory operations of prehension, mastication, insalivation, and deglutition, the apparatus proper to digestion consists of the stomach, the duodenum or the second stomach, the jejunum, and the ileum, the three latter portions of the alimentary canal forming the small intestines. It is in these great digestive chambers that the processes of chymification and chylification are performed; processes by which the multifarious substances taken as food are converted into an homogeneous substance analogous in its composition to the blood. The requisite changes on the food are effected partly by secretions formed by the walls of the digestive chambers themselves, and partly by secretions elaborated by distinct organs and conveyed into the digestive chambers by separate tubes. These auxiliary organs are the pancreas and the liver, the fluids secreted by which perform a most important part in the function of digestion. The chyle, the ultimate result of the action of these digestive fluids, is absorbed, as it is formed, by a set of vessels termed the lacteals, spread out upon the walls more especially of the jejunum and ileum, upon the surface of which they take their origin by open mouths.

But a considerable portion of the substances taken as food is incapable of being converted into chyle; this is separated from the chyle partly in the duodenum, and still more perfectly in the jejunum and ileum, as it flows over the walls of these extended chambers. Moreover, a considerable portion of the digestive fluids themselves does not enter into the composition of the chyle, but is separated from it and mixed with the refuse matter of the food. Again, the whole extent of the alimentary canal, from its commencement to its termination, is lined with a membrane which secretes a peculiar fluid, termed mucus. This fluid which defends the delicate and sensitive vessels that are crowded on every point of the digestive chambers, and which maintains those chambers in a state of suppleness and moisture, is constantly formed, removed, and renewed. That portion of it which has served its office, and which has become effete, is mixed with the refuse matter of the aliment and of the digestive fluids. All these substances mixed together in a common mass are transmitted to the second portion of the alimentary canal, which consists of the large intestines; namely, the cæcum, the colon, and the rectum, by the operation of which the second part of the digestive function, that termed fæcation, is performed. This function consists of two processes; first, of that by which the common mass of excrementitious substances is brought into a state fit for its discharge from the body; and secondly of that by which a force is generated adequate to effect its discharge. The chief agent by which these substances are brought into a state fit for their discharge is the bile. [BILE; in NAT. HIST. DIV.] The agent by which their actual discharge is effected is the muscular coat of the intestines, which is excited to contraction, and thereby to the generation of the force requisite to the accomplishment of the object, by the stimulus of the bile.

It is obvious, then, that the matters to be discharged from the alimentary canal do not consist, as is vulgarly supposed, merely of the refuse portion of the food: this constitutes only a small part of those matters; an essential part of it consists of the refuse matter of secretions which have performed most important offices in the economy.

There is manifest in the performance of certain functions of the body a tendency to periodicity. The most remarkable of these are the return, at regular periods, of the necessity for sleep, of the appetite for food, and of the command to remove from the body the excrementitious matters prepared in the alimentary canal. Whatever may have first led to the formation of these habits, and however they may be varied by circumstances which operate at an early period of life, they cannot, after having been once formed, be materially and frequently interrupted without danger to the health. The interruption of one of these habits

* The Avis Indica of Bayer. [Correct *Apis* Indica in BAYER, BIOG. DIV.]

† Crater is a separate constellation in Ptolemy. The neighbouring stars on the body of Hydra were considered by Flamsteed as part of this constellation.

‡ This is the Apis of Bayer, called Musca by Lacaille; there is, however, a constellation Musca, formed by Bode, we believe, and situated close to Aries, the stars of which are usually considered as belonging to Aries.

§ A part of Aquila in Aratus.

‖ Only one in Aratus and Ptolemy. Another added by Hevelius.

by the retention of the fæces beyond a determinate period, namely, the period of twenty-four hours, constitutes the disease termed constipation; a disease often disregarded, generally considered of little importance, always productive of mischief, and very frequently terminating in a fatal result.

The slighter degrees of constipation, when, as is sometimes the case, they are attended with no appreciable disturbance of any function, can scarcely be considered as morbid; but, in general, a retention of the fæces beyond the period of twenty-four hours, is attended with manifest disorder. This disorder is commonly increased in proportion as the retention is protracted beyond that determinate period, and in proportion to the frequency with which such retention recurs. The amount of the disorder thus induced is, however, a good deal influenced by constitutional peculiarity; for there are individuals whose fæcal evacuations are not more frequent than once a week, or once a fortnight, or even once in three weeks. Such an habitual retention of the fæces, in the few cases in which it occurs, generally happens in females who lead a sedentary life, and who take little food and less exercise.

The immediate effects of constipation, when this disease occurs in its usual degree, in ordinary habits, is the production of some one or more of those painful states, the signs of which are generally grouped together under the common name of dyspepsia. There is disordered appetite, which is either deficient, capricious, or voracious; a dry, coated, or clammy tongue; thirst, or some disagreeable taste in the mouth; dulness, heaviness, confusion, giddiness, or pain in the head; physical and mental torpor; dry and hot skin; and last, though not least, an irritable temper, and a capricious or a desponding mind.

The remote effects of constipation are far more numerous and serious than is commonly understood. It is impossible to enter into a full detail of them in this place. But among the most obvious may be mentioned, the origin of various diseases of the skin.

Moreover, headache and giddiness existing as severe and permanent affections, and the distinct diseases called colic [Colic], chorea [Chorea], epilepsy, chlorosis, hysteria, hæmorrhoids, and many others, have their most frequent origin in an habitual and protracted retention of the fæces.

The usual termination of constipation when severe, frequent, and obstinate, is in inflammation of the intestines, which commonly assumes the form either of ilius [Ilius] or enteritis [Enteritis], and which rapidly proves fatal.

There is, without doubt, a greater tendency to constipation in some temperaments than in others; in the melancholic, for example, than in the sanguineous, and in certain individual peculiarities of constitution. But this tendency would appear to be capable of being superinduced by the habitual use of certain kinds of indigestible food; such as imperfectly fermented bread, heavy pastry, as dumplings, &c.; indigestible vegetables, as cucumbers, melons, &c. The tendency thus superinduced may be greatly increased by the use of astringent and stimulating beverages, sedentary habits, long indulgence in sleep, &c. The immediate causes of constipation are: 1. an impaired or torpid action of the liver, in consequence of which there is either a deficient or a vitiated secretion of bile. It has been stated that one portion of the bile [Bile, Nat. Hist. Div.] mixes as an essential constituent with the chyle, by which the nutritive part of the food is assimilated to the constitution of the blood; the other portion of the bile consists of excrementitious matter, principally of a resinous nature. It is this resinous portion of the bile that constitutes the proper stimulus to the colon and rectum, whose office it is, by the contraction of the fibres which form their muscular coat, to remove the fæcal matters from the body. A certain change in the quantity or quality of the bile must therefore necessarily diminish the action of these organs, by depriving them of the stimulus on which their action mainly depends. 2. Torpor of the muscular coat of the alimentary canal itself, and more especially of that portion of it which constitutes the large intestines. 3. The production and accumulation of flatus in these organs, by which their thin parietes are distended, and even a mechanical obstacle is afforded to the passage of the fæces.

The treatment of constipation should always have in view two objects: 1. The immediate removal of the impacted fæces; and 2. The change of the pathological condition of the system in general, or of the alimentary canal in particular, on which the fæcal retention depends.

CONSTITUTION, a term often used by persons at the present day without any precise notion of what it means. Such a definition of a constitution, if it were offered as one, might be defended as equally good with many other definitions or descriptions which are involved in the terms used whenever a constitution is spoken of.

The constitutions which are most frequently mentioned are the English constitution, the constitution of the several states composing the North American Union, the federal constitution, by which these same states are bound together, and various constitutions of the European continent, which have hardly been permanent enough to be submitted to an accurate investigation.

The *vague* notion of a constitution is that of certain fundamental rules or laws by which the general form of administration in a given country is regulated, and in opposition to which no other fundamental rules or laws, or any rules or laws, can or ought to be made.

The *exact* notion of a constitution cannot be obtained without first obtaining a notion of sovereign power. The sovereign power in any state is that power from which all laws properly so called proceed; it is that power which commands and can enforce obedience. Such a power, being sovereign or supreme, is subject to no other power, and cannot therefore be bound by any rules laid down, either by those who have at any previous time enjoyed the sovereign power in the same community, or by any maxims or rules of conduct practised or recommended by its predecessors in power, whether those rules or maxims be merely a matter of long usage or solemnly recorded in any written instrument. The sovereign power for the time is supreme, and can make what laws it pleases without doing any illegal act, and, strictly speaking, also, without doing any unconstitutional act. For this word constitution, taken in its strongest sense, can never mean more than a law made or a usage sanctioned by some one or more possessed of sovereign power, which law or usage has for many generations been observed by all those who have successively held the sovereign power in the same country. To modify or destroy such a rule or law might be unwise, as being an act in opposition to that which many successive generations had found to be a wise and useful law; it might be dangerous as being opposed to that to which the prejudices of many generations had given their sanction; and it might lead to resistance on the part of the governed, if either their own interest or their passions were strong enough to lead them to risk a contest with the sovereign power. If (as would generally be admitted) the assembled parliament of Great Britain and Ireland possess the sovereign power, there is no act which they could do which would be illegal, as every body must admit: and further, there is no possible act which they could do which would be unconstitutional, for such act would be no more than repealing some law or usage having the force of law which the mass of the nation regarded with more than usual veneration, or enacting something at variance with such law or usage. For example, if the next assembled parliament should abolish the trial by jury in all cases, except criminal matters, or where the crown is the prosecutor, such an act might be called by some illegal, unconstitutional, and unwise. But it would not be called illegal by any person who had fully examined into the meaning of the word law; it would not be called unconstitutional by any man who, having called it illegal, wished to be consistent with himself: it could only properly be called wise or unwise by those who had reflected sufficiently on the nature of the institution and its operations to know whether such a modification would do more good or harm.

The words constitutional and unconstitutional appear to be only strictly applicable to such a case as the following: where the sovereign power being invested in one, or two, or five hundred, or all the males of an independent political community who are above a certain age, or in any other number in such a community, lays down certain rules to regulate the conduct of those to whom the sovereign power intrusts the legislative functions. Such are the Constitutions of the several states composing the North American Union, and such is the Constitution of the Federation of these several states. In these several states the people, in the mass, and as a general rule, are the sovereign. The people assembled by their delegates, named for that especial purpose, have framed the existing Constitutions; and they change the Constitutions in the same way whenever the majority of the people, that is, when the sovereign, chooses to make such change.

These Constitutions lay down certain rules, according to which the legislative, executive, and judicial functionaries must be chosen; they fix limits to their several powers, both with respect to one another, and with respect to the individuals who compose the sovereign. They do ordain and declare the future form of government. For example, the Constitution of Virginia of 1776, declares "that all ministers of the Gospel of every denomination shall be incapable of being elected members of either House of Assembly, or of the Privy Council." The same rule, we believe, forms a part of the recently amended Constitution of the same state. If the Virginia legislature were to pass an act to enable clergymen to become members of the House of Assembly or of the Privy Council, such an act would be unconstitutional, and no one would be bound to obey it. The judiciary, if such a matter came before it, would, in the discharge of its duty, declare it unconstitutional, and such co-called law could have no further effect than if any unauthorised body of men had made the rule.

A constitution then is nothing more than an act of the sovereign power, by which it delegates a part of its authority to certain persons, or to a body, to be chosen in a way prescribed by Act of Constitution, which at the same time fixes in a general way the powers of the body to which a part of the sovereign power is thus delegated. And the sovereign power changes this Constitution whenever it pleases, and in doing so acts neither constitutionally nor unconstitutionally, but simply exercises its sovereign power. No body can act unconstitutionally but a body which has received authority from a higher power, and acts contrary to the terms which fix that authority. Wherever then there is a sovereign power, consisting either of one, as the Autocrat of Russia, of three members, king, lords, and commons, as in England (provided these three members do possess the complete sovereign power), or of all the males born of American citizens and of a given age, as in most of the United States of North America—such sovereign power cannot act unconstitutionally. For to act unconstitutionally would be to act against a rule imposed by some superior authority, which would be a contradiction.

A constitutional government may be either purely democratical, as those of the United States of North America, or it may be republican, that is, a government in which the sovereign power is simply defined as not being held by one person. It may be of such a kind that it shall approach very near to a monarchy, if the king or other head of the state is by the constitution invested with very great powers, or such powers as may enable him to overpower, overawe, or render incapable of action, the other limbs of the Constitution. A constitutional government may be of the aristocratical kind, as England, where the power of the crown is now very limited in practice, and is in effect wielded by the small number who for the time obtain the direction of affairs by means of being able to get a majority of the House of Commons; for this body, though elected by the people, cannot yet be considered as a really popular body. The French king, under the Charter, had greater powers than the English monarch has in fact, though in theory it may seem otherwise. The King of the French presided in his own Cabinet; the English Cabinet deliberates without the presence of the sovereign, whose wishes, in opposition to those of the Cabinet, can never be carried into effect. The Cabinet consists of the responsible ministers; they are the king's servants, but so long as they are in office they act as they please. But whatever variety of form there may be in constitutional governments, the essential element to a constitutional government, as here understood, is an assembly of representatives chosen by all the people, or by a considerable proportion of them. This is the body on which a constitutional government depends for its strength, its improvement, and its existence. This is the element out of which ought to come all the ameliorations of the condition of the people which can be effected by legislative measures. The limb or member of a constitutional government, which is composed either of hereditary peers, or of peers named for life by a king, is from its nature an inert body. It may resist unwise and hasty change, but it is not adapted for any active measures.

The policy of having a constitution in a state where the sovereign power is in the hands of all the citizens may be defended on general grounds of convenience. When the community have settled that certain fundamental maxims are right, it is a saving of time and trouble to exclude the discussion of all such matters from the functions of those to whom they have by the constitution intrusted legislative power. Such fundamental rules also present a barrier to any sudden and violent assumption of undue authority either by the legislative or executive, and oblige them, as we see in the actual workings of constitutions, to obtain their object by other means, which, if not less dangerous in the end, are more slow in their operation, and thus can be detected and are exposed to be defeated by similar means put in action by the opposing party. There are disadvantages also in such an arrangement. Constitutional rules when once fixed are not easily changed; and the legislative body when once established, though theoretically, and in fact too, under the sovereign control, often finds means to elude the vigilance and defeat the wishes of the body to which it owes its existence, and from which it derives its power. One of the great means by which these ends are effected is the interpretation of the written instrument or constitution, which is the warrant for their powers. The practice of torturing the words of all written law, till in effect the law or rule is made to express the contrary of what seemed to be at first intended, appears to be deeply implanted in the English race, and in those of their descendants who have established constitutional forms on the other side of the Atlantic. The value of all written instruments, whether called constitutions or not, seems considerably impaired by this peculiar aptitude of men to construe words which once seemed to have one plain meaning only, so that they shall mean anything which the actual circumstances may require, or may seem to require.

It is beside our purpose to discuss the advantage of a Constitution in a community where the sovereign is one. Being supreme, the sovereign may change the Constitution when he pleases. It may be said that if the constitution is good, and has been allowed to stand by several successive possessors of the sovereign power, it obtains an apparent prescriptive authority, which is the more binding on the sovereign, as the mass of the nation habitually regard this same Constitution as something which even the sovereign cannot touch with impunity. It would shock common prejudice if the actual sovereign were to violate that which has been sanctioned by his predecessors, and is recommended by an apparently higher antiquity than the power which, in the actual sovereign's hands, appears to be of more recent birth. The precise meaning of what is called the English Constitution must be got from the various writers who have made its origin and progress their study. In reading them it may not be amiss to bear in mind that the word Constitution, as used by them, has not the exact, but the vague meaning as explained above.

States where there is a king, or other person with corresponding name and power, are now most usually distributed into the two classes of monarchies and constitutional monarchies. The term Monarchy is a proper term to express a form of government in which one man has the sovereign power, as in Russia. The term Constitutional Monarchy is not an appropriate term, because the word monarchy is not capable of a limitation of meaning without the implication of a contradiction in terms. Still the expression is used, and it is understood to express those states in which the kingly power is limited or defined by a written instrument, which also lays down certain general rules affecting the form of government and the condition of the people, which are not to be varied by any legislative act. Such an instrument was the French Charte [CHARTE], under which France, instead of being a monarchy, as it was once, became a constitutional state, or, as it is called, a constitutional monarchy. This act, which proceeded from the king (Louis XVIII.), could not be revoked by any future king consistently with good faith; and its attempted violation by Charles X. produced a revolution.

When a nation has reached a certain point in its social progress, a participation in the sovereign power becomes a universal desire. It does not follow that a nation will be better administered because the people participate in the sovereign power, but they will not be satisfied till they do participate in it; and that is the important matter for an absolute power to consider. The representatives may often, and will certainly sometimes, enact laws which are mischievous to themselves; but that is an incident to, or an accident in, a constitutional system, not its essential. The essential of a constitutional system is, to call all men into political activity as members of a state, to secure the highest degree of individual freedom that is consistent with the general interest; to establish a real national character, by making each man a potential and living member of the body corporate; and, above all, to keep a tight and steady hand upon the public purse; to see that no more taxes are raised than are necessary for the due support of the administration, and to see that they are raised in such a way as to bring the largest sum into the treasury with the least detriment to the individual. Freedom of publication, or, as it is usually called, the liberty of the press, is in modern times indispensable as a means of maintaining constitutional freedom where it exists, and of attaining it where it does not. In Prussia it is restrained by a censorship; in France it is checked by severe enactments, together with a system of warning, and a power of suspending the publication of newspapers. In England the freedom of the press is amply secured both by law and usage. In the actual state of Germany, in which political life hardly exists, the establishment of a true constitutional government in Prussia would be the commencement of a new era for the Germanic nation. The Russian subjects of the Czar of Muscovy, or of the greater part of his dominions at least, may be at present as contented and as well governed as they would be under a constitution; for a constitution, in order to be beneficial, must be founded upon a representation of a whole nation which has political knowledge, or of a majority so large that the minority shall be insignificant when compared with it.

In the article CHARTE an account is given of the constitution of France; and of that of the UNITED STATES of NORTH AMERICA, in GEOG. DIV., under that head; America and England enjoy a higher degree of constitutional freedom than any other states. Since 1848 Sardinia has possessed a representative constitution, and has still more recently acquired a free press. The struggles of Prussia and the results will be found in the GEOG. DIV., under PRUSSIA. Spain has made extraordinary efforts to obtain the advantages of a constitution. [CORTES.] Some of the smaller states of Germany have constitutions, as Würtemberg, Hanover, Baden, Hesse Darmstadt, Hesse Cassel, Nassau, &c. The European States which have no constitution are Russia, Austria, the Ottoman Empire, Naples and Sicily, the Papal States, Grand Dukedom of Tuscany, Dukedom of Parma, Dukedom of Modena, Dukedom of Lucca, &c. The constitutions of Mexico and of the Republics of South America resemble, in some respects, that of the United States, but have not yet acquired stability. Brazil has a constitution and a representation.

For the nature of a federal government, which necessarily implies the notion of a constitution, see FEDERATION.

CONSTITUTIONS AND CANONS ECCLESIASTICAL. King James I., in the first year of his reign in England, by his writ directed to the Archbishop of Canterbury, summoned and called the "bishops, deans of cathedral churches, archdeacons, chapters and colleges, and the other clergy of every diocese within the province of Canterbury," to meet in the cathedral church of St. Paul in London, to "treat, consent, and conclude upon certain difficult and urgent affairs mentioned in the said writ." The persons so summoned met in convocation, and "agreed upon certain canons, orders, ordinances, and constitutions, to the end and purpose" by the king "limited and prescribed unto them;" to which the king, out of his "princely inclination and royal care for the maintenance of the present estate and government of the Church of England by the laws of this realm now settled and established," gave his royal assent by letters patent, according to the form of the statute of the twenty-fifth year of King Henry VIII. The king, by his prerogative royal and supreme authority in causes ecclesiastical, commanded these said canons, orders, and constitutions to be diligently observed, executed, and kept by his loving subjects of the kingdom, both within the provinces of Canterbury and York, in all points wherein they do or may concern every or any of them; and the king also commanded that every minister, by whatever name or title soever he be called, shall in the parish church or chapel where he hath charge read all the said canons, orders, ordinances, and constitutions once every year, upon some Sundays or holydays, in the afternoon before divine service.

The canons and constitutions may be divided into fourteen heads, which treat as follow: 1. Of the Church of England. 2. Of divine service, and administration of the sacraments. 3. Ministers, their ordination, function, and charge. 4. Schoolmasters. 5. Things appertaining to churches. 6. Churchwardens, or quest-men, and side-men, or assistants. 7. Parish clerks. 8. Ecclesiastical courts belonging to the archbishop's jurisdiction. 9. Ecclesiastical courts belonging to the jurisdiction of bishops and archdeacons, and the proceedings in them. 10. Judges ecclesiastical and their surrogates. 11. Proctors. 12. Registrars. 13. Apparitors. 14. Authority of synods. The number of constitutions is one hundred and forty-one. The authority of these canons is binding on the clergy, but not on the laity, except so far as is stated under the head Canon. The authority of Canon 77 may be doubted; it is this: "No man shall teach, either in public school or private house, but such as shall be allowed by the bishop of the diocese, or ordinary of the place, under his hand and seal; been found meet as well for his learning and dexterity in teaching, as for sober and honest conversation, and also for right understanding of God's true religion; and also except he shall subscribe to the first and third articles afore-mentioned simply, and to the first ten clauses of the second article." The 78th Canon provides that "curates desirous to teach shall be licensed before others:" and the 79th declares "the duty of schoolmasters." The Constitutions and Canons Ecclesiastical were printed by the Society for Promoting Christian Knowledge, London, 1841, together with the Thirty-nine Articles of the Church of England.

CONSTITUTIONS, APOSTOLICAL or CLEMENTINE, are a code of regulations, attributed by some ecclesiastical writers to the Apostles, and said to have been collected by Clemens Romanus. The collection consists of eight books, containing a great many precepts and rules concerning the discipline, doctrine, and ceremonies of the church.

Besides the gospels, epistles, and apocalypse, which now compose the volume of the New Testament, there were, in the earliest ages of Christianity, numerous writings bearing the name of the apostles and apostolical men, of which some are extant at the present time; and it is generally considered that two among the first in order of time are the eight books of Apostolical or Clementine canons, and the Constitutions which are the subject of the present article. That the latter once constituted a part of the New Testament, is evident from the last of the apostolical canons, which states that "The holy and venerable Bible consists of the Old Testament (of which the several constituent books are enumerated) and the New Testament, which consists of the gospels of Matthew, Mark, Luke, and John; 14 epistles of Paul; 2 of Peter; 3 of John; 1 of James; 1 of Jude; 2 of Clement, and the *Constitutions* for you that are bishops, published by me Clement in 8 books, which are not to be divulged to all, because of the mystical things contained in them; and the Acts of the Apostles." (Labbei, 'Collect. Concil.' tom. i.) One of the epistles of Clement, and part of the other which is attributed to him, are included in the Alexandrine MS. Epiphanius (A.D. 400) cites the Constitutions not only as the work of an honest Catholic Christian, but as the divine word and doctrine; yet in his catalogue of canonical books they are not included, and it is contended that the constitutions now extant are not identical with those from which Epiphanius cited.

The authenticity and date of this work have been a subject of much learned contention; and though by far the greater number of critics have pronounced it to be a pseudonymous compilation, made in the third or fourth century, there have been some who support the opinion of its apostolical origin. (See Tillemont, 'Mémoires pour l'Hist. de l'Église,' vol. ii.; Mosheim, cent. i., part ii.; and Neander, 'Genetische Entwickelung,' &c.

CONSTITUTIONS, ROMAN. The word constitutio (from constituere, that is, to set up, to establish) signifies any disposition or appointment; for example, in Dig. iv. 2, l. 9, § 3, an interlocutory decree of the prætor is called constitutio; whilst in D. 45, l. 91, 3 and 4, the expression "quod veteres constituerunt" is used to signify a legal rule or maxim in use among the old Roman lawyers. The decrees and decisions of Roman emperors are also called constitutiones, and, according to Gaius (i. 5), an imperial constitution is what the emperor declares by a decree, or an edict, or a letter. That modern signification of the term, which denotes the fundamental law of a state, was not in use among the Romans; yet Cicero ('De Republica,' i. 45) employs the word to express a similar notion.

During the republic the Roman law was made or developed by decrees of the people in the comitia (leges and plebiscita), by decrees of the senate, and by the edicts of various magistrates, as the prætors and ædiles. [Roman Law.] After the great internal change and revolutions had taken place in the Roman state, and Augustus had united in himself the powers of all the branches of government, with the direction of the senate, and of the assemblies of the people, the imperial authority was firmly established. The emperor not only had the right of issuing edicts, as the magistrates of the republic had done, but he could propose and make entirely new laws. Propositions of laws from the emperor to the senate were called orationes principum. Thus arose the imperial constitutions, with the supremacy of Augustus. But as the arbitrary acts of Sulla, Pompeius, and Julius Cæsar were ratified and confirmed by the people, both in their lifetime, and after their death, this may be considered as the beginning of the system of constitutions. As the institutions of the republic only gradually merged into the imperial autocracy, the voice of the people in the comitia and the decrees of the senate were still respected in form, though not in substance. But after A.D. 24, during the reign of Tiberius, the legislation of the people, and 200 years later the decrees of the senate also, totally ceased. From that era laws were made only by the emperors; and from the time of Constantine the Great, the constitutions were properly called leges novæ, or new laws.

The imperial constitutions occur under different denominations; as edicta (leges edictales), or decrees addressed to and binding on all Roman subjects; decreta or rescripta, which are decisions in particular cases, upon questions proposed to the emperor by public functionaries or private persons; these decisions also were universally binding. We find the terms epistolæ also used, when the decisions were answers to magistrates, and litteræ, when given in reply to private persons. Important single constitutions were often entitled from the emperor who made them, as, for example, "lex Anastasiana."

In course of time the number of these constitutions became so great, that to prevent confusion collections were made, and called codes. The first collections made by private persons were the codices Gregoriani and Hermogeniani, of which we know very little; it being even uncertain if they were two separate codes or only one. Yet it seems that the first collector was Gregorius, and that Hermogenes continued the work. Opinions vary also as to the time when these compilers lived; Blume fixes on the reigns of Diocletian and Maximian, as the period when Gregorius or Gregorianus flourished, resting his hypothesis on a mutilated inscription found in one of the rescripts in his code, in which Blume traces the words "Diocletianus et Maximianus Domini Nostri." (See Irving's 'Introduction to the Civil Law,' p. 28, n. 29.) Hugo thinks it probable that both these lawyers flourished during, or a little after Diocletian's reign ('History of the Roman Law,' book 2, § 379): in a note to that section he mentions as a curious fact that in an old treatise, the 'Consultatio veteris Jurisconsulti,' an extract from the corpus Hermogenianum is ascribed to the reigns of Valentinian and Valens, nearly 100 years later. Their collections, which contained the constitutions from the time of Hadrian to Diocletian, are lost, and we have only some fragments, which were first edited by Jac. Sichardus (Basil, 1528, fol.), together with the Codex Theodosianus. The fragments are in Schulting's 'Jurisprud. Vet. Ante-Just.,' Lugd. Bat. 1712, and in the 'Jus Civile Ante-Just.,' Berol. 1815, purporting to be taken ex Breviario Alariciano; but a more recent and a very valuable edition of these constitutions has been published by Hänel, at Bonn, 1835, entitled 'Codicis Gregoriani et Codicis Hermogeniani Fragmenta.' In connection with the Theodosian code a remarkable document discovered by Clopius deserves mention, the 'Gesta in Senatu Urbis Romæ de recipiendo Theodosiano Codice,' containing the announcement to the senate of Rome by the consul A. A. Glabrio Faustus of the emperor's legislative enterprise, and the other's concurrence, "Quam rem æternus princeps dominus noster Valentinianus, devotione socii affectu filii comprobavi," together with the approbation with which that announcement was received. Nor should the student of this portion of the ante-Justinianean Roman law omit to refer to a work of much research and sound learning for an admirable illustration of the history of the Theodosian era, in Bishop Müller's 'Commentatio historica de Genio Moribus et Luxu Ævi Theodosiani.'

Another and more important collection was made in the reign of Theodosius II., by public authority. The emperor having nominated, in the year 435, a commission of eight persons, including Antiochus, who was their director, for the purpose of collecting the constitutions from the time of Constantine the Great, three years afterwards (A.D. 438) the new code, called Codex Theodosianus, was confirmed by the emperor, and published in the Eastern empire. It contains sixteen books, divided into titles, in which the separate constitutions are arranged, according to their subject-matter, in such a way that many of them are subdivided. Some additions, called novellæ, were afterwards made to the collection of Theodosius. The first five books were lost, but portions of them have been recently discovered at Milan, by Clossius (Clossii 'Theodos. Codic. Genuin. Fragmenta,' Tüb. 1824); and at Turin, by Peyron, ('Codic. Theodos. Fragm. Ined.,' Tur., 1823-4). The best edition of the Theodosian Code is that by Jac. Gothofredus, tom. vi., Lugd., 1665, who also wrote an excellent commentary on it, which was published, together with the text, by Ritter, Leipzig, 1736-54. A copy of this code has appeared in the Berlin edition (1815) of the 'Jus Civile Ante-Justinianeum.'

In the year 506, Alaric II. made an abridgement of the Theodosian Code, adding to it the excerpts from the codices Gregoriani and Hermogeniani, and the works of the Roman lawyers Gaius and Paulus, for the use of the Romans then living in the empire of the Visigoths; the collection is called 'Breviarium Alaricianum,' and is also known by the title 'Aniani Breviarium.'

The last and most important collection of Roman constitutions was made by the order of Justinian. [Justinian's Legislation.]

CONSTRUCTION (Geometry). All formation of lines, figures, &c.,

which is not absolutely implied in the hypothesis of the problem or theorem in question. Thus, in the proof of the theorem, "the square on the hypothenuse of a right-angled triangle is equal to the sum of the squares on the sides," the formation of the right-angled triangle and of the squares is not technically considered as part of the construction, the latter term being only used to imply all the additional formation of figure necessary to the proof.

A question is frequently said to be solved by construction, when it is only meant that a geometrical method of solving it is adopted, as distinguished from an algebraical solution. An equation is also sometimes said to be constructed, in the sense inverse to that in which it is said to be solved; that is, when the roots are given, and the equation is required to be found.

CONSUBSTANTIAL (Consubstantialis) is equivalent in expression to co-essential, and is the translation of the term *ὁμοουσίος*, homoousios, which, in the commencement of the 4th century, was the subject of so much zealous contention among the Trinitarian and Unitarian sects of Christians. The Arians and Eusebians, who asserted the second person of the Trinity, and the adherents of Macedonius, who asserted the third person, to be different and distinct in nature from the first, were strenuously opposed by the Athanasians, who, at the council of Nice (A.D. 325), adopted as the pass-word of their party the term *ὁμοουσίος*, consubstantial, or, as it is Englished in the Nicene creed, "*Of one substance* with the Father." There were three conflicting denominations: those who held the three persons to be of the *same* substance, *ὁμοουσίος*; those who asserted them to be of a *similar* substance, *ὁμοιουσίος*; and those who contended that they were of a *different* substance, *ἀνομοίος*. Between these parties the dispute was carried on during several years with great violence; and successive councils, composed of hundreds of bishops, continued to meet for the purpose of altering creeds and reciprocating anathemas. In modern times the *ἀνομοῖος* doctrine has been advocated by Dr. Bury in his 'Naked Gospel,' a work which, though condemned and burnt by the University of Oxford, was approved and adopted by Locke, Clarke, and Whiston. The circumstantial particulars of the ancient controversy may be found in the various histories of the councils of that period, and its modern revival in the numerous works on the Unitarian doctrines. See especially the article 'Arianisme,' in Plugnet's 'Dict. des Hérésies.'

CONSUBSTANTIATION, or **IMPANATION**, is a term adopted by the Lutheran Church to designate its doctrine of the Eucharist, in contradistinction to the transubstantiation of the Church of Rome. Luther, after separating from the Roman Catholic communion, still retained the doctrine of the real presence; but instead of teaching, as the Romanists do, that the priest's pronunciation of the words of consecration at once deprive the bread and wine on the altar of their natural qualities, and transform them into the real body and blood of Christ, he taught that after the consecration of the bread and wine, they are mysteriously *accompanied* with the real body and blood. In short, in *transubstantiation*, the divine body and blood is present *without* the bread and wine; and in *consubstantiation* it is present *with* the bread and wine: the former effects a change of nature, the latter a change of circumstance.

The Lutheran doctrine of consubstantiation was first introduced into the church by John, surnamed Pungens Asinus, a doctor of Paris, at the end of the 13th century. His work on this subject, entitled 'Determinatio F. Joannis Parisiensis de modo existendi Corpus Christi in Sacramento Altaris,' was republished by Allix in 1686.

CONSUL (a word of the same family as *consulere*, to consult), was the title of the highest ordinary magistrate in the Roman republic. King Tarquinius Superbus having been expelled from Rome for his tyrannical conduct, by the joint efforts of the patricians and plebeians, B.C. 409, a republic was established. Instead of kings, two functionaries called consuls (consules, in Greek ὕπατοι) were appointed to administer the republic. The first consuls were Lucius Junius Brutus and Lucius Tarquinius Collatinus (or M. Horatius, according to Polybius, iii 22). The consuls were annually elected in the Comitia Centuriata, and at first were only chosen from the patricians.

As the consulship was established in the place of the kingly office, the consuls also were invested with the same power that the kings had. (Niebuhr's 'History;' Gibbon's 'History,' i. 3; Cicero, 'De Leg.' iii. 3, who ascribes to them "regiam potestatem"). The consulate was, with the exception of the dictatorship, the highest, and, before prætor, ædiles, and censors existed, the only superior administrative office in Rome. The consuls were at the head of the whole republic; the judiciary (jurisdictio), the military (imperium), and the executive powers were all united in them. Accordingly, we find them also called prætores, and judices, and imperatores. They presided in the senate, where they had an elevated seat, and the business in the comitia curiata and centuriata was conducted by them. The consuls created the quæstors of the public treasury, and thus had great influence in the administration of the treasury, the quæstors being dependent on them. They could also conclude peace and make alliances. They were the supreme judges in all suits and criminal trials.

The consuls possessed the same external insignia of honour as the kings, except the golden crown and the trabea (purple cloak), which latter they were only allowed to wear in a triumph. They had a sceptre of ivory, with an eagle at the end. In the assemblies of the people they sat on the sella curulis (an ornamented chair); and like the other senators they wore the toga prætexta. Twelve lictors, with the fasces and axes, as the symbol of the consuls' power over the lives of the citizens, preceded each of them at first; but P. Valerius, called Poplicola, a name which implies his respect, or affected respect, for popular rights, limited the power of the consuls, and curtailed the external symbols of their authority. In the city, the axes were taken from the fasces, and only one of the consuls was preceded by the twelve lictors. From their sentence appeals to the people were allowed. From this time they were deprived of their former power of condemning citizens to death in Rome, and the power of scourging them only remained. But while they were at the head of the army out of Rome, they retained the axes in the fasces and all their former rights. The consul who, according to the settlement of Valerius, was not preceded by the twelve lictors, had a public slave, called accensus, to precede him. The right to the twelve lictors and the supreme authority in matters of administration were enjoyed by the consuls alternately from month to month.

The patricians, after expelling the kings with the help of the plebeians, designed to transfer the royal power to themselves, which they accomplished by securing the election of both consuls out of their own body. The consuls therefore being invested with the supreme power, the struggle of the people with the patricians was at the same time a struggle against the consuls. Their power sustained a great shock by the institution of the tribunes of the plebs. Each of the tribunes, whose number at last amounted to ten, had the right of putting his veto on the measures of the consuls. In order to prevent arbitrary acts of the consuls, the tribune Terrentius, B.C. 461, made a proposition for a code or collection of laws, and in the year B.C. 452 ten men (decemviri) were named for this purpose, who were invested with full powers, and all other functionaries for the time were suspended. The consulate being re-established, the tribunes, B.C. 444, proposed that the people should choose consuls from the plebeians also, a proposal which gave rise to a long and violent contest. The consulship was again suspended, and tribunes of war (tribuni militares) with consular power were appointed, to which office plebeians also were made eligible. At last, B.C. 366, the first plebeian was elected consul. (Liv. vi. 42; vii. i. 2, 21-6.) Afterwards both consuls were on several occasions plebeians.

In the mean time the extension of the state made it impossible for the consuls to perform the increased duties of their office, and new functionaries were created. In B.C. 442, the censors, and B.C. 365, the prætors, were created, which latter had the judicial functions previously attached to the consulate. In relation to these new magistrates, the consul was called magistratus major, or superior magistrate.

Though the consular power was thus much diminished, it was still very great. All the officers of the state, except the tribunes, were under the consuls; they summoned the meetings of the senate, received all despatches, and gave audiences to foreign ambassadors. In time of war they were commanders-in-chief, and the election of the military officers partly depended on them. In critical times the consular power was made unlimited by the decree of the senate, "videant consules ne quid respublica detrimenti capiat" (they should take care that the republic sustained no harm). Under such circumstances they could require the strictest obedience from all the citizens; and they resumed their right to condemn to death without appeal.

The imperium or military command was granted to the consuls by the lex curiata [COMITIA], whereby a province (*provincia*) was assigned to them. The term *provincia* originally denoted the power given to discharge some public duty out of Rome, particularly the command of the army in conquered countries; and these countries themselves were called provinciæ (provinces). When a consul, after the expiration of his term of office, was appointed to govern a province, he was called pro-consul.

At first no particular age was a necessary qualification for the consulate. But by the lex Annalis, proposed by the tribune L. Villius, in the year B.C. 181, a certain age was required for each magistrate; and the consul must be forty-three years of age. But this law was not always observed; M. Valerius Corvus was elected consul in his twenty-third, and Scipio Africanus in his twenty-eighth year. No one could legally be re-elected till after an interval of ten years; but M. Valerius Corvus was re-elected six times and Marius seven times.

The candidate for the consulate was required to be at Rome when the election took place in the comitia centuriata, a rule which was also sometimes not regarded. The elder of the two consuls first received the fasces, until the Emperor Augustus prescribed, by the law called lex Julia and Papia Poppæa, that he should take them first who had most children. The time of election varied at different periods of the Commonwealth; but they were always chosen some time before they entered on office, and were called designati. The time of entrance on office likewise varied; but about B.C. 154 it was fixed that they should always enter on their office on the 1st of January. The years were named after the consuls, and annual registers were kept for that purpose, which were called Fasti Consulares. When the consuls entered on their office, they went in a solemn procession to the capitol to sacrifice to Jupiter Capitolinus; and after this ceremony the senate held a solemn session. Within the five next days they were to take the oath to administer the republic according to the laws; and at the end of their term of office they took a similar oath. Those who had discharged the office of consul were called consulares, and enjoyed a kind of pre-eminence in rank over the other senators.

Consular Medal of M. Agrippa.

British Museum. Actual size. Bronze. Weight, 158 grains.

From the time of Sulla and Cæsar, who were elected perpetual dictators, the consulate gradually lost all its powers, and under the emperors it sunk to a mere shadow and a name. Yet consuls were still annually elected by the people, until the time of Tiberius, who ordered that they should be chosen by the senate. The number of the consuls was much augmented by the emperors; and several kinds of consuls were made, as consules ordinarii, after whom the years still were called; consules suffecti, elected by the emperors; and consules honorarii, who had title and rank, but no power. In the reign of Commodus there were as many as twenty-five consuls in one year. Constantine, however, restored the custom of appointing two consuls only in the year, one for Constantinople, and one for Rome, who were alone to act as supreme judges under the emperor. The last consul at Constantinople, after whom the year was denominated, was Basilius, junior, in the year 1294 A.U.C. or 541 A.D., in the reign of the Emperor Justinianus. The last consul at Rome was Theodorus Paulinus, in the year A.D. 536.

CONSUL, an officer appointed by a government to reside in some foreign country, in order to give protection to such subjects of the government by whom he is appointed as may have commercial dealings in the country where the consul resides, and also to keep his employers informed concerning any matters relating to trade which may be of interest or advantage for them to know. To these duties are sometimes superadded others having objects more directly political, but into this part of a consul's duty it is not necessary to enter at present, as such functions are assigned to consuls not as such, but in the absence of an ambassador or other political agent. The duties of an English consul, as such, cannot perhaps be better described than by giving the substance of the general instructions with which he is furnished by the government on his appointment.

His first duty is to exhibit his commission, either directly, or through the English ambassador, to the authorities of the country to which he is accredited, and to obtain their sanction to his appointment: the document whereby this sanction is communicated, is called an exequatur; its issue must precede the commencement of his consular duties, and its possession secures to the consul "the enjoyment of such privileges, immunities, and exemptions, as have been enjoyed by his predecessors, and as are usually granted to consuls in the country in which he is to reside" It must be the particular study of the consul "to become conversant with the laws and general principles which relate to the trade of Great Britain with foreign parts: to make himself acquainted with the language and with the municipal laws of the country wherein he resides, and especially with such laws as have any connexion with the trade between the two countries." It is the consul's principal duty "to protect and promote the lawful trade and trading interests of Great Britain by every fair and proper means;" but he is at the same time "to caution all British subjects against carrying on an illicit commerce to the detriment of the revenue and in violation of the laws and regulations of England, or of the country in which he resides;" and he is to give to his own government notice of any attempt at such illicit trading. The consul is "to give his best advice and assistance, whenever called upon, to her Majesty's trading subjects, quieting their differences, promoting peace, harmony, and good-will amongst them, and conciliating as much as possible the subjects of the two countries upon all points of difference which may fall under his cognisance." Should any attempts be made to injure British subjects in person or in property, he is to uphold their rightful interests and the privileges secured to them by treaty. If, in such cases, redress cannot be obtained from the local administration, he must apply to the British minister at the court of the country in which he resides, and place the matter in his hands. The consul must transmit to the Secretary of State for Foreign Affairs, at the end of every year a return of the trade carried on at the different ports within his consulate, according to a form prescribed. He is also required to send quarterly an account of the market prices of agricultural produce in each week of the preceding three months, with the course of exchange, and any other remarks which he may consider necessary for properly explaining the state of the market for corn and grain. It is further his duty to keep his own government informed as to the appearance of any infectious disease at the place of his residence. The consul is required to afford relief to any distressed British seamen, or other British subjects thrown upon the coast, or reaching by chance any place within his district, and he is to endeavour to procure for such persons the means of returning to England. He is to furnish intelligence to the commanders of queen's ships touching upon the coast where he is, and to obtain for them, when required, supplies of water and provisions, and he is to exert himself to recover all wrecks and stores belonging to queen's ships when found at sea, and brought into the port where he resides.

In most cases consuls are subjects of the state by whom they are appointed, but this is by no means an invariable rule, and they are sometimes the subjects of the country in which they reside, or of some other country foreign to both. In some of the less important places, vice-consuls are selected for filling the office from among the mercantile class, and it occasionally happens that they are engaged in commercial pursuits at the port where their official residence is fixed.

Consuls or vice-consuls are appointed by the English government, at all the chief ports with which the nation has commercial relations, but the precise number is always varying. The salaries paid vary not only in the manner above stated, but likewise according to the particular circumstances attending the appointment, a residence in some countries being necessarily more expensive than in others. In addition to their salaries, consuls are in the receipt of fees on signing various documents, but these fees are of small amount.

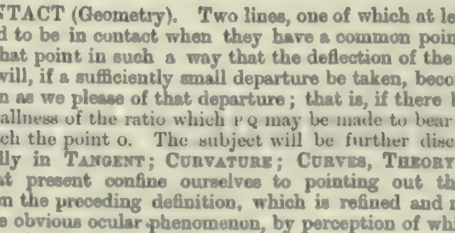
CONSUMPTION, PULMONARY. [Phthisis Pulmonalis.]

CONSUMPTION, MESENTERIC. [Marasmus.]

CONSUMPTION, in political economy, is the end of production; the use, the expenditure, of articles produced. It is unnecessary here to enter upon any examination of the theories of *productive* and *unproductive* consumption, which have so largely occupied the attention of writers upon political economy. We have stated the general principle under the head Capital. The natural relations between production and consumption appear very unlikely to be greatly disturbed in any condition of society in which there is freedom of labour and security of property. The most injudicious and extravagant consumption on the part of the few is, in its degree, a stimulus to a more strenuous production on the part of the many; and under these circumstances there is sure to be that excess of production over consumption which constitutes capital. The creation of capital shows that the production has been greater than the unproductive consumption. A judicious and well-regulated expenditure on the part of the few would doubtless afford a more certain encouragement to the industry of the producers, and the excess of production over consumption would, in the long run, be greater. Whatever injury the improvident consumption of individuals may cause to themselves, it is quite clear that the producing class of society will always repair the waste of the spending class: that in point of fact there will be an excess of production over consumption, wherever the course of industry is not impeded by bad laws, or by a wasteful consumption on the part of a government. Whenever a government engages in the ruinous consumption incidental to war, for example, a very powerful stimulus may indeed be given to particular branches of industry; but other branches of industry that would have been encouraged had their money remained in the pockets of the tax-payers, will proportionately be depressed. The compensating power of production that is called forth in all cases of private consumption must be deranged, or unequally and therefore imperfectly excited, by the consumption of the state.

CONTACT (Geometry). Two lines, one of which at least is curved, are said to be in contact when they have a common point, and recede from that point in such a way that the deflection of the one from the other will, if a sufficiently small departure be taken, become as small a fraction as we please of that departure; that is, if there be no limit to the smallness of the ratio which P Q may be made to bear to O N, as we approach the point O. The subject will be further discussed mathematically in Tangent; Curvature; Curves, Theory of; and we shall at present confine ourselves to pointing out the connection between the preceding definition, which is refined and mathematical, and the obvious ocular phenomenon, by perception of which we immediately admit a marked difference of character between *contact*, as shown at S, and simple *intersection*, as shown at R.

All our perceptions of lines being ocular and physical in the first instance, there is a *minimum visibile*, or least visible distance, at which lines will run into each other. Now if P Q and O N always preserve such a ratio to each other that the *minima visibilia* of these lines arrive nearly together, P Q will not be lost to sight before O N, and the curves will continue distinct up to the very point of meeting. But if P Q diminish so rapidly as compared with O N, as to be lost to sight while



ON is still visible as a length, the two curves will appear to coincide for a visible length, which forms the principal ocular feature of contact. But this *practical* contact is not admitted in geometry, a science of reason, in which no length is considered as invisible; so that contact is only said to exist where the ratio of PQ to ON diminishes—not merely very much—but without limit. Let ON and PQ be the fractions x and v of a linear unit. If then v diminish without limit when compared with x, but always retain a finite ratio to x^2, the contact is said to be *of the first order;* if v also diminish without limit when compared with x^2, but always retain a finite ratio to x^3, the contact is said to be of the second order, and so on. These different orders of contact exhibit nothing to the eye but a closer approach, the higher the order of contact; except in this, that contacts of an even order are always accompanied by the *intersecting* coincidence shown at S, while contacts of an odd order make the curves tangent to each other in the sense in which the word is used by Euclid, as at T.

CONTAGION, THE MATTER OF, a poison which, on entering the blood, produces a definite train of morbid phenomena, and which communicates to the blood the property of generating a similar poison, capable of producing precisely similar morbid phenomena. Considered as a morbific matter *sui generis,* contagion, then, is an agent which produces a disease of a definite nature, one of the distinctive characters of which is that in its progress a peculiar matter is secreted from the blood, which, when introduced into the blood of another individual, produces precisely the same disease. The term contagion is also in common use to denote the actual propagation of diseases of a specific nature from person to person. Such diseases, so propagated, are called contagious; and the matter by which they are propagated is called contagious matter or contagion.

The disease called small-pox exhibits a series of morbid phenomena peculiar to itself. These peculiar phenomena constitute it a distinct or generic disease. The pustules formed in its progress, the formation of which is one of the series of morbid phenomena distinctive of it, contain a peculiar secretion, a specific poison, which, on being introduced into the blood of a person previously in sound health, as by inoculation, produces in that person small-pox. This disease, then, presents all the characters of a contagious disease.

According to the etymological signification of the term, the propagation of disease from person to person by contagion depends on the actual contact of the body which receives with that which communicates the poison. But direct contact is not indispensable to the propagation of a contagious disease. There are contagious diseases which are absolutely incommunicable without direct contact; but there are others which are capable of communication both by contact and without it. A particle of the matter of small-pox, for example, placed in direct contact with the body, will produce small-pox; but the matter of small-pox is likewise capable of being dissolved or suspended in the air; and the air thus loaded with small-pox matter, on coming in contact with the body, is capable of producing small-pox. Hence contagious diseases are divided into two great classes; into those in which the contagious matter acts only by positive contact of person with person, and into those in which it acts both by positive contact and through the medium of the air. Contagion may therefore be said to be immediate or mediate, contactual or remote.

Contagion is carefully to be distinguished from infection. [INFECTION.]

CONTEMPT. A contempt in law is a disobedience of the rules, orders, or process of a court of justice, or a disturbance or interruption of its proceedings. Contempts by a contumacious resistance to the process of a court, such as the refusal of a sheriff to return a writ, are punishable by attachment; but contempts done in the presence of the court, which cause an obstruction to its proceedings in administering the law, may be punished or repressed in a summary manner by the commitment of the offender to prison or by fining him. The power of enforcing their process, and of vindicating their authority against open obstruction or defiance, is incident to all courts; and the means which the law intrusts to them for that purpose are attachment for contempts committed *out of* court, and commitment and fine for contempts done *in facie curiæ.* [ATTACHMENT.]

CONTENT (contentus, contained), the quantity of space contained in any portion of space, measured by the number of times which some arbitrary unit is contained in the space. Thus, linear content is simply LENGTH; superficial content is AREA or surface; solid content (in which sense the word is principally used), also called volume, is the number of solid units contained in a space. These solid units are always cubes, described on the unit of length. Thus, when the inch or foot is employed in measuring lengths, the cubic inch or cubic foot is always employed as the measure of solid content.

The solid content of a rectangular parallelopiped (or figure like a box) is found by multiplying together the units in the lengths of its three dimensions. Thus, 3 feet of length, 2¼ feet of breadth, and 4 feet of height, give 3 × 2¼ × 4, or 30 cubic feet.

The solid content of any cylinder or prism is found by multiplying together the number of square units in the base and the number of linear units in the altitude; and one-third of a similar product is the content of a pyramid or a cone. The content of any irregular solid bounded by planes must be found by dividing it into pyramids.

Weight is thus connected with content accurately enough for common purposes. Multiply the number of cubic *feet* by 1000 times the specific gravity; the result is the number of ounces avoirdupois. Roughly, multiply the number of cubic feet by the specific gravity; and five-ninths of the result is the number of cwts. Thus, the specific gravity of brick being 2, a cube of bricks 20 feet long every way weighs $\frac{5}{9}$ of 20 × 20 × 20 × 2, or 8889 cwt.

To find the solid content of a sphere, take $\frac{377}{90}$ths of the rad. × rad. × rad. Thus, the radius of a sphere being 4 feet, the number of cubic feet contained is 4 × 4 × 4 × 377 ÷ 90, or 268 1.

CONTINGENT REMAINDER. [REMAINDER.]

CONTINUED BASE, in Music, is the figured base of a score used throughout, and so called to distinguish it from the vocal base, as well as from the base staves assigned to particular instruments. The term is only to be found in very old music, and is now become obsolete.

CONTRABAND. [CUSTOMS DUTIES.]

CONTRACT. [AGREEMENT.]

CONTRACTION, in Surgery, an abnormal and permanent alteration in the relative position and forms of parts, arising from various causes. Under the heads ANCHYLOSIS, and DISTORTION, some of the more remarkable results of contractions have been pointed out. In this article we shall describe the nature of club-foot and wry-neck, and point out the recent mode of treating these contractions by surgical operation, which has been remarkably successful.

Club-foot, *Talipes,* is the term which has been applied to all kinds of distortion of the foot. Four species have been described: *talipes varus,* distortion of the foot inwards; *talipes valgus,* eversion of the foot; *talipes equinus,* forced extension; and *talipes calcaneus* or *talus,* extreme flexion of the foot upon the leg. Till within a recent period it was a generally received opinion, that all forms of club-foot consisted in a malformation of the bones of the tarsus, more particularly the astragalus, and this malformation was traced to a diseased condition of the bones. It is a curious fact, however, that Hippocrates attributed club-foot to the unnatural contraction of one set of ligaments and the elongation of another. Whether this be the original cause of the distortion may be doubted, but there can be no doubt as to its being a result, and that the only malformation which exists in the parts is removed by relieving the contraction of the ligaments. It is, however, to Delpêch in modern times that we are indebted for a sound view of the nature of club-foot, and more particularly for suggesting, though himself unsuccessful, the modern operation for its relief. Two cases of club-foot, which had been produced after the bones had attained their full development, led him to regard the irregular action of the muscles as the cause. To this conclusion also Stromeyer of Berlin was led, by an inquiry in which he engaged, on the occurrence of paralysis in the muscles of inspiration. The following are the various sources of distortion dependent upon irregular action of the muscles, according to Dr. Stromeyer.

1. Structural changes in the muscles, inflammation and wounds, with loss of substance.
2. Debility and inactivity of antagonists, produced either by wounds of tendons or the bellies of antagonist muscles, or by paralysis of the nerves of antagonist muscles.
3. Diminution of voluntary power in the entire limb through which the flexors or extensors preponderate over the extensors or flexors by the constant organic contraction of the muscles.
4. Painful affections of the part, restraining or prohibiting motion, such as that from inflammation of a joint.
5. Increased energy in the muscle, morbid contraction or motion in the muscular fibres, tonic spasm.

The various modes of treatment of club-foot formerly pursued indicated the want of a definite knowledge of its nature. They were mostly mechanical, and seldom effected the object they had in view. The mode of treatment now more generally pursued is the use of mechanical means after the performance of a surgical operation. The operation consists in dividing the tendons of the contracted muscle, which admits of the restoration of the malformed parts to their normal position, and the space between the divided ends of the tendon is filled up with new matter, and the function of the muscle is normally performed. This operation, simple as it is, was never performed till the year 1784, when Lorenz, a surgeon at Frankfort, divided the tendo-achillis for the cure of a case of club-foot, under the direction of Thilenius. The same operation was afterwards unsuccessfully resorted to by Sartorius and Michaelis. In 1816 Delpech again attempted it, and upon more philosophical principles than his predecessors, but he also failed. This did not prevent Stromeyer from repeating the operation in 1831, which was perfectly successful. In 1833 and 1836 he published two memoirs, containing six successful cases. It was speedily performed again by several surgeons in England and on the Continent, and the value and utility of the operation are now universally admitted. The principal rule to be observed in the operation is not to cut through more parts than is necessary, and to divide the tendon of the contracted muscle. The division of the tendo-achillis is however only calculated to relieve talipes equinus and the slighter cases of varus. But in the severer forms of varus, the tendons of the tibialis posticus, flexor longus pollicis, and sometimes of the tibialis posticus, require division. In valgus the tendons of the peronei as well as the tendo-achillis require division. The principal part of the treatment takes place after the operation, and consists of applying various mechanical means for the restoration of the parts to their normal position. This treatment is generally commenced from two to four days after the operation. A great variety of apparatus have been designed for the purpose, but each case requires a peculiar adaptation of the means for effecting the reduction of the parts.

Club-hand does not occur so frequently as club-foot, but the distortion is of precisely the same nature, and requires for its removal the application of the same measures.

Wry-neck (*Caput obstipum, Torti-collis*) is a disease of the same nature as the preceding, and most frequently arises from the unequal contraction of the muscles of the neck, originating in some one of the causes previously mentioned. The consequence is that the head is permanently inclined towards one of the shoulders. Sometimes this disease arises from disease in the vertebræ or from the contraction of cicatrices after severe wounds and burns of the neck. In the former case the wry-neck can seldom be removed, but in the latter the cicatrix may sometimes be advantageously divided, and the wound allowed to heal again with the head in its natural position. Where it depends on contraction of the muscles, the same operation may be had recourse to as is used for the relief of club-foot and club-hand. It is a curious fact that the operation for dividing the muscles in wry-neck had been recommended and practised long before it was found to be generally applicable to the treatment of contractions. When it is determined to treat wry-neck by mechanical means without operation, the best apparatus is that of Jörg. It consists of a pair of leather stays, and of a band or fillet which goes round the head. To the stays is attached a pulley, over which runs a band to the back of the ear, in the direction of the muscles of the neck, and which can be tightened by means of a screw. It thus acts on the head as the muscles would do if they were in action.

Dr. Little of London has recently published a work on the application of the Stromeyerian operation to contractions depending on what is called partial ankylosis. These ankyloses depend upon some organic or functional lesion of tendon or muscle, arising from one of the following causes: 1. From sloughing or adhesion. 2. From spasmodic contraction. 3. From organic contraction through paralysis of antagonist muscles. 4. From contraction owing to long-continued rest of the limb. When this kind of ankylosis has not existed for a great length of time, or occurs in young persons, a division of the contracted muscle, and a careful extension of the limb afterwards, is very often followed by a complete restoration of the function of the ankylosed joint.

The same causes which produce the above-named diseases give rise to the irregular action of the eye called squinting, and the operation of Stromeyer has been found perfectly successful in this deformity. [SQUINTING.]

(Little, *On Ankylosis*; Little, *On Club-Foot*; Cooper's *Surgical Dictionary*; Cooper, *First Lines of Surgery*; Articles 'Anchylosis' and 'Club-Foot,' *Cyclopædia of Surgery*.)

CONTRALTO; CONTRATENOR. [ALTO.]

CONTRARY and CONTRADICTORY. Two propositions are commonly said by logicians to be contrary when the one denies every possible case of the other; and to be contradictory, when one being universal, the other denies some of the things asserted in the first. Thus, the contrary proposition to "every A is B" is, "no A is B," and its contradictory is, "some As are not Bs."

Contrary propositions may be both false, but cannot be both true; as in "all angles are equal," and "no angles are equal." But of contradictory propositions one must be true and one must be false; either "all angles are equal," or "some angles are not equal." One of the most common fallacies of conversation and debate (and occasionally of written argument) is fixing the assertion of the contrary upon one who simply contradicts. And, on the other hand, nothing is more common than to assume a contrary as proved upon grounds which establish only the contradictory.

The most easy way of establishing general propositions is, in many cases, the refutation of the contradictory; and here is another source of error, since the refutation of the contrary is frequently supposed to have the same effect.

In common language, the two words are used in the same sense; persons are said to maintain *contrary* sides of an argument, when their conclusions are not the technical contraries of the logicians, but only contradictory of each other. The common question, "Have you anything to say to the *contrary?*" always means, "Can you *contradict* this?"

CONVENT, from the Latin *conventus*, an assembly or meeting together. This word is used in a double sense, first, for any corporation or community of religious, whether monks or nuns; and secondly, for the house, abbey, monastery, or nunnery in which such monks or nuns dwell. Shakspere uses it in the first sense, when he says of Wolsey—

"At last, with easy roads, he came to Leicester,
Lodged in the abbey; where the reverend abbot
With all his convent honourably received him."
Hen. VIII., act iv., sc. 2.

Addison uses it for the building:—"One seldom finds in Italy a spot of ground more agreeable than ordinary that is not covered with a convent."

Furetière, who wrote his dictionary in the time of Louis XIV., says there were no fewer than 14,000 convents formerly in France.

Convent, as related to the foreign military orders, meant the principal seat or head of the order. Furetière says, "La Commanderie de Boisy, près d'Orleans, est le Convent général de l'Ordre de St. Lazare."

The earliest inhabitants of convents were termed Cænobites, from the Greek words *κοινός* and *βίος*, as living in community. They dwelt chiefly in Egypt. Fleury ('Hist. Eccles.,' 4to, tom. v. p. 14, Paris, 1720,) dates their institution as early as the days of the Apostles; others, probably with more correctness, give them a later origin. St. Pachomius, abbot of Tabenna, on the banks of the Nile, who was born at the close of the third century, is believed to have been the first person who drew up a rule for the Cænobites. (Moreri, 'Dict. Histor.,' tom. viii.) [MONASTERY.]

CONVENTION, MILITARY, a treaty made between the commanders of two opposing armies concerning the terms on which a temporary cessation of hostilities shall take place between them. It is usually solicited by that general who has suffered a defeat, when his retreat is not secure and small chance is left of maintaining his position; and it is seldom refused by the victor, since without incurring the unavoidable loss attending an action, his force becomes immediately disposable for other operations.

In 1757 the Duke of Cumberland, when in danger of being surrounded, entered into a convention with the Duke de Richelieu, through the medium of Denmark, by which, on consenting to disband all his auxiliaries, he was allowed to retire with the English troops across the Elbe. And in 1799, when the Anglo-Russian army failed in the attempt to deliver Holland from the French power, the Duke of York made a treaty with General Brune by which the invading force was allowed to re-embark on condition that 8000 French and Dutch prisoners of war in England should be restored.

After the battle of Vimeira in 1808, the Duke of Abrantes, having been defeated, and fearing a general rising in Lisbon against him, sent General Kellerman to the quarters of the British commander-in-chief, to request a cessation of arms, and propose a convention by which the French troops might be allowed to retire from Portugal. This being granted, it was finally arranged in the convention that they should not be considered as prisoners of war; and that, with their property, public and private, their guns and cavalry horses, they should be transported to France: on the other hand, all the fortresses which had not capitulated were to be given up to the British, and a Russian fleet, then in the Tagus, was to be detained in English ports till after the conclusion of a peace. This is the celebrated convention which was made at Lisbon, and is generally but improperly called "of Cintra." It excited much dissatisfaction both in Portugal and England. (Napier, vol. i.) By the appointment of a committee consisting of one individual of each of the three nations, all causes of complaint were, however, finally removed.

CONVENTION PARLIAMENT. Two days after the abdication [ABDICATION] of James II., the Prince of Orange invited the lords spiritual and temporal, to the number of about ninety, who had taken their places in the House of Lords, together with such persons as had sat in Parliament in the reign of Charles II., to the number of about a hundred and fifty, with the aldermen of London, and fifty of the common council, to meet him, and he requested them "to consider the state of the country, and to communicate to him the result of their deliberations." They did so, and the recommendation was that he should summon a convention of the estates of the realm. The prince accordingly despatched circular letters to the several counties, universities, cities, and boroughs, for the election of members. The convention, or parliament, as it was afterwards declared to be, passed the Act of Settlement, which declared the throne vacant, and conferred the crown, with constitutional limitations to its power, on the Prince and Princess of Orange jointly. The Convention Parliament was dissolved 29th January, 1691. (See "Popular History of England," by Charles Knight, vol. iv., p. 443, *et seq.*)

CONVENTION TREATIES. These are treaties entered into between different states, under which they each bind themselves to observe certain stipulations contained in the treaty. In 1848 two acts were passed (6 & 7 Vict. c. 75 and c. 76) for giving effect to conventions between her Majesty and the King of the French and the United States of North America for the apprehension of certain offenders.

The act relating to France (c. 75) legalises the convention entered into with the government of that country for the giving up of offenders who may escape from France into England. On requisition duly made by the French ambassador, a warrant will be issued for the apprehension of fugitives accused of having committed the crimes of murder (as defined by the French code), attempt at murder, forgery, or fraudulent bankruptcy; and any justice before whom they may be brought is authorised to commit them to jail until delivered up pursuant to the ambassador's requisition. Copies of the depositions on which the original warrant was issued, duly certified as true copies, are to be received as evidence. But no justice is to issue a warrant for the apprehension of any French fugitive unless the party applying is the bearer of a warrant or document, issued by a judge or competent authority in France, authenticated in such a manner as would justify the arrest of the supposed offender in France upon the same charge. The secretary of state will order the person committed to be delivered up to the person or persons authorised to receive him. If the prisoner committed shall not be conveyed out of her Majesty's dominions within two months from the time of his committal, any of her Majesty's judges, on application made to them, and after notice of such application has been sent to the secretary of state (or to the acting governor in a colony), may order such person to be discharged, unless good cause shall be shown to the contrary. The act is to extend to all her Majesty's present or future possessions, and to continue in force during the continuance of the convention.

The act relating to America (c. 76) is similar in its nature and purposes to the one relating to France; but the crimes specified include, in addition, piracy, arson, and robbery, and do not include fraudulent bankruptcy. Difficulties, however, have arisen as to the jurisdiction of either country as to crimes committed at sea. A murder may be committed on an English subject on board an American vessel (or vicé versâ), and in whichever country it arrives it is undecided whether either country has jurisdiction over the case.

In 1844 a case occurred of a fraudulent French bankrupt who had escaped to England, and the French government demanded that he should be given up under the Convention Treaty. He was arrested and taken to prison; but before the surrender could take place he applied for writ of habeas corpus, on the ground that fraudulent bankruptcy was an offence unknown to the law of England, and that therefore it was contrary to law to arrest him or keep him in custody on such a charge. The warrant of commitment did not specify that the prisoner should be given up on requisition duly made according to the act, but the words were, "until he shall be delivered by due course of law." In consequence of the defective application of the Convention Treaty in this particular case the prisoner was discharged.

CONVERGENT, CONVERGENCY, DIVERGENT, DIVERGENCY. When a series of numbers proceeding without end, has terms which diminish in such a manner that no number whatsoever of them added together will be as great as a certain given number, the series is called convergent. But when such a number can be added together as will surpass any given number, however great, the series is called divergent. Thus, of the two following series—

$$1+\frac{1}{2}+\frac{1}{4}+\frac{1}{8}+\text{, \&c., and } 1+\frac{1}{2}+\frac{1}{3}+\frac{1}{4}+\text{\&c.,}$$

the first is convergent, for no number of its terms, however great, will amount to 2: the second is divergent, and the sum of its terms may be made to exceed any number. By going a mile, then half a mile, then a quarter of a mile, &c., two miles could never be completed: but by going a mile, then half a mile, then one-third of a mile, &c., a hundred million of miles, or any greater number, could be surpassed.

The subject of the convergency of series is one of fundamental importance in the whole of the mathematics; but it is only recently that it has been treated, in works on algebra, in the manner which its importance requires. Algebraical writers once imagined that a series, however obtained, is safe and fit for use, whether convergent or divergent. This opens a question which has caused much discussion, and on which we cannot here enter. We shall state the results of investigation on the subject, together with the references to sources of information.

1. Series of increasing terms are certainly divergent.

2. Series of decreasing positive terms are divergent, unless the terms diminish without limit.

3. Of series of positive terms which diminish without limit, a test of convergency or divergency may frequently be given as follows. Let a, b, c, d, e, &c., be the terms of the series: form the new series

$$\frac{b}{a}, \frac{c}{b}, \frac{d}{c}, \frac{e}{d}, \frac{f}{e}, \text{ \&c. } \ldots\ldots \text{(A)};$$

then, if there ever arrive a term of the series (A), from and after which all the terms are not only less than unity, but tend towards a limit which is less than unity, the series is certainly convergent: but if the terms aforesaid become greater than unity, and continue so from and after a given term, the series is certainly divergent: and if the limit in the first case be not less than unity, but unity itself, the series may be either convergent or divergent, and each particular case must be examined by itself. Instances of both sorts can be given.

4. Series of the form $a+bx+cx^2+dx^3+ex^4+$&c., can always be made convergent by giving a sufficiently small value to x, except only in the case where the terms in the series (A) increase without limit from and after any term. If they do not increase without limit, let L be the limit; then the preceding series is convergent whenever Lx is less than unity, is referable to the preceding case when Lx is equal to unity, and divergent when Lx is greater than unity. But if $L=0$, the preceding is always convergent.

5. Series whose terms are alternately positive and negative, are always convergent when the terms diminish without limit, and the error committed by taking any number of terms to stand for the whole value, is never so great as the first term thus rejected. For instance, if the answer to a question be $1-\frac{1}{2}+\frac{1}{3}-\frac{1}{4}+$ &c., then 1 is not wrong by $\frac{1}{2}$, $1-\frac{1}{2}$ is not wrong by $\frac{1}{3}$, $1-\frac{1}{2}+\frac{1}{3}$ is not wrong by $\frac{1}{4}$, and so on. The results are alternately too great and too small.

6. When such a series as the last has its terms not diminishing without limit, but towards a finite limit, the sum of any number of terms, increased by half the limit, is never wrong by so much as the first-rejected term differs from the limit.

7. When series produced by algebraical development have their terms alternately positive and negative, the error committed by stopping at any term is never, *in any case which the student will meet with*, so great as the first rejected term, even though the series become afterwards one of continually increasing terms. If, then, such a series have the first few terms rapidly diminishing, a close approximation may be made by means of them to the real value of the expanded function. For instance, in the series $1-2x+2.3x^2-2.3.4x^3+\ldots.$ (in which an attempt to calculate from the whole series would be utterly futile, since, however small x may be, there must be terms of every degree of magnitude) when x is small, an approximation may be made to its value from the terms which decrease. Thus if $x=\cdot 1$, in which case the series is

$$1-\cdot 2+\cdot 06-\cdot 024+\cdot 0120-\cdot 00720+\text{\&c.,}$$

(and the first term which surpasses that preceding, is $2.3.\ldots.11\,x^{10}$): the aggregate of the terms up to $2.3\ldots.9x^8$ inclusive, will not differ from the true value of the expression by so much as $2.3\ldots.10x^9$, or ·0036288. The proof of this curious proposition, in the vast number of cases in which it is true, may be deduced from Lagrange's Theorem on the Limits of Taylor's Series. ('Lib. Useful Knowledge,'—Differential Calculus, p. 73.)

Series which are functions of x may be divided into—1. Those which are sometimes convergent, and sometimes divergent, such as the development of $(1+x)^n$. 2. Those which are always convergent at last, but in which the appearance of divergency (increasing terms) may be continued as long as we please, such as the development of ϵ^x. 3. Series which are always divergent, but to which a similar appearance of convergency can be given, such as $1+2x+2.3x^2+\ldots.$, and the like. 4. Series which are always convergent or always divergent, and never can be made to exhibit any symptom of approach to the other state, such as

$$x+\frac{1}{x}+\left(x^2+\frac{1}{x^2}\right)+\ldots \text{ and } \frac{x}{1+x^2}+\frac{x^2}{1+x^4}+\ldots$$

The series which are always convergent, both in reality and appearance, and upon which, therefore, an arithmetical algebraist would reckon with most security, do, in fact, offer difficulties of a very peculiar character. They are the only ones in which the usual algebraical generalisations would lead to absolute error (so far as has yet appeared).

On this subject generally, see Peacock's 'Algebra,' and 'Report on Analysis' ('Rep. Brit. Assoc.,' vol. ii.); Cauchy, 'Cours d'Analyse;' Grunert, 'Supplemente zu Klugel's Wörterbuche der Reinen Mathematik,' in the article 'Convergenz der Reinen;' 'Encyc. Metrop.,' article 'Calculus of Functions.' See also SERIES.

CONVERSE. We here state the ordinary theory of the logical converse. Converse, in logic, means a proposition which is formed from another by interchanging the subject and predicate, thus: the converse of "Every A is B" is "Every B is A." But care must be taken to put the proposition in its usual logical form before conversion. Thus the converse of "Every A has a B" is not "Every B has an A." For the proposition first stated is

$$\text{Every}\begin{bmatrix}\text{A}\\ \textit{subject}\end{bmatrix}\begin{bmatrix}\text{is}\\ \textit{copula}\end{bmatrix}\begin{bmatrix}\text{a thing which has a B}\\ \textit{predicate.}\end{bmatrix}$$

and the converse is "Every thing which has a B is an A."

Of the four forms to which all assertions can be reduced, namely (A) "Every A is B"; (E) "no A is B"; (I) "some As are Bs"; (O) "some As are not Bs", the logical converses (so called) are those in which the new subject appears with the same degree of generality of assertion as the old one. Thus the converse of "Every A is B", is "*Every* B is A.' Consequently in the first and fourth forms, or the general affirmative and the particular negative, the logical converse is not necessarily true. Thus "Every A is B,' does not give "Every B is A" *necessarily*, but only "some Bs are As'. The latter is called by writers on logic conversion *per accidens*, a term which, as Dr. Wallis has declined to explain it, we shall leave as we find it, adopting the phrase diminished or limited conversion, and calling the first kind simple conversion. The only other method of conversion which has a definite name is that in which the subject and predicate are made contradictory to the former ones, as when we convert the proposition, "All equilateral triangles are equiangular triangles," into "All triangles not equiangular are triangles not equilateral." This is called conversion by contra-position. Restricting ourselves to converses which are necessarily as true as the direct propositions, we have the following rules with respect to A, E, I, and O above.

E and I are simply convertible.

E and A are convertible by diminution.

A and O are convertible by contra-position.

Nothing is more apt to make a beginner believe that "Every A is B" yields "Every B is A," than the study of geometry without close attention to the meaning of terms and the force of the parts of an assertion. For as a majority of the earlier propositions have their simple converses true, the student does not sufficiently reflect upon this being contingent and not necessary.

In mathematical propositions there is a species of conversion which has no name, consisting in the interchange of the predicate with a part only of the subject. Thus if P, Q, R, and S be four circumstances, of which the existence of any three makes the fourth also exist, we may observe this species of conversion in passing from the first to the second of the following propositions:—

Every (thing which gives P, Q, and R) is (a thing which gives S).

Every (thing which gives P, Q, and S) is (a thing which gives R).

Thus of the following set of circumstances: 1. That two figures be parallelograms; 2. That they be equiangular; 3. That the sides about equal angles be reciprocally proportional; 4. That the areas be equal: exhibit the possibility of this conversion. For (1) (2) and (3) give (4); (1) (2) and (4) give (3); (1) (3) and (4) give (2).

The subject of converse is discussed by Aristotle, 'Analytic. Prior.,' i. cap. 2, &c. See the editions of the 'Organon,' by Pacius, 1597, &c.

CONVERSION. [Trover.]

CONVEX. [Concave.]

CONVEYANCE (in Law) is a deed or instrument in writing which passes real or personal property. The only conveyances used in the earlier periods of English history seem to have been feoffments and grants, though leases were soon used to pass a limited interest. The possession of land, as well as property of a moveable nature, passed by tradition or actual transfer. The possession of land was given symbolically, by the delivery of a twig, a turf, &c., the charter of feoffment being the evidence merely of the transaction, and not essential to its validity. Hence, in the charter of feoffment, the operative words, or those which expressed the gift or transfer of the property, were used in the past tense, *hath given*, &c.: these terms are still used by some practitioners, although the reason for them has long since passed away.

A grant was applied to the conveyance of incorporeal hereditaments which did not admit of actual delivery into possession. From this difference in their application, a diversity was supposed to exist in the innate qualities of the two modes of conveyance, the feoffment being used to convey the actual possession of land, and operating upon the possession without any regard to the estate or interest of the feoffor; the grant to transfer the right of the grantor to the grantee: the former was formerly defined as a tortious, the latter a rightful conveyance. This definition however was not always recognised by the courts (see Goodright *v.* Forrester, 1 Taunt, 613). The stat. 8 & 9 Vict. c. 106, formally abolished a distinction which often led to inconvenient consequences, and now no feoffment can have a tortious operation.

Sir William Blackstone distinguishes conveyances as original or primary, which are those by means of which the benefit or estate is created, or first arises; and derivative or secondary, whereby the benefit or estate originally created is enlarged, restrained, transferred, or extinguished. This division however is of little practical importance. Conveyances operate either according to the rules of the common law, or under the statute of uses. Conveyances may be further divided into those made by matter of record and by deed. As examples of those by matter of record, we may mention private acts of parliament, and the queen's grant; and, until those modes were abolished by the statute 3 & 4 Will. IV., c. 74, fine and recovery. Those by deed are by feoffment, grant, bargain and sale, covenant to stand seised, lease, release or confirmation, exchange, surrender. Conveyances simply transferring personal property are called assignments.

By the statute 13 Eliz., c. 5, voluntary or fraudulent conveyances of real property are rendered void, as against the creditors of the party making the transfer: and the 27th Eliz., c. 4, extends similar, and in some instances more extensive, relief to subsequent purchasers of the same property, although they may have had notice of the prior conveyance. The bankrupt and insolvent laws also provide for the relief of creditors against certain conveyances of real and personal property in derogation of their claims, or made within a specified time previous to the bankruptcy or insolvency.

The old system of conveying by lease and release has been effectually uprooted by the simple enactment of the statute 8 & 9 Vict, c. 106, to the effect that "all corporeal tenements and hereditaments shall, as regards the immediate freehold thereof, be deemed to lie in grant as well as in livery."

In many of the states of North America a simple bargain and sale is the usual mode of conveying real property. In New York it is called a grant; and the conveyance by feoffment and livery of seisin, and also the statute of uses, are expressly abolished by the legislature.

Conveyances in Scotland are made according to the strict principles of the feudal law there established, which imparts to them the appearance of far greater speciality and quaintness than those used in modern English practice.

(Bl. *Comm.*; Butl. *Co. Litt.*; Kent's *Comm.*)

CONVEYANCING is the business of preparing conveyances of real or personal property, of investigating the title of the vendors and purchasers of property, and of framing those multifarious deeds and contracts which govern and define the rights and liabilities of families and individuals. It is carried on by barristers, or by members of the Inns of Court, who having kept twelve terms, obtain a certificate according to the provisions of the 9 Geo. IV., c. 49, and are called certificated conveyancers. [Barrister; Inns of Court.] The increased number of transactions in this branch of the law has rendered a division of labour and a special course of study necessary.

There are two opposite systems, by which the transfers and transactions of the owners of real property are capable of being carried on; and between the extreme points of which, in some portion or other of the intermediate ground, all existing systems must arrange themselves. In one of these systems, as in the present sytem of England, every transaction is accomplished and evidenced by means of instruments in writing, varying infinitely, and governed by a scientific and ascertained mode of construction. In the other, the effect is accomplished somewhat like the transfer of stock, by a comparatively mechanical operation, a process of book-keeping, of which the evidence is to be kept, not in private muniments, but in the ledger-books or registers of the State.

The respective objects of these systems are, in the one, to protect the rightful owner; in the other, the innocent purchaser. In the latter the State takes upon itself the duty of seeing to the title of the owner whom it admits to registration, and consequently takes upon itself the risk of being deceived; in the former, it leaves the parties to concert titles and transfers in secret and in silence, leaves them unrestrained and unchecked to transact with one another, but compensates this want of interference by the alternative of following the right, by its judicial machinery, against all parties, however ignorant, however innocent, who may have had the misfortune, at any time subsequent to a defective transaction, or wrongful succession, to become the owners or purchasers of the property; limiting that restoration or succession only by reference to certain durations of adverse possession. (Parke's 'Lect.')

In the time of the feudal law, and the period immediately succeeding, restraint was placed on every species of alienation; landed property was rarely the subject of barter. Every transfer of land took place in open court, that is, on the land itself *coram paribus* (before the pares or peers), who were the other tenants of the feudal lord, and who subscribed the instrument of investiture as witnesses (Sulliv. 'Lect.,' p. 58); so that, in the words of Lord Mansfield, it was as notorious who was feudal tenant *de facto*, as who is now *de facto* incumbent of a living, or mayor of a corporation. Land was "of a stubborn nature," money portions were unknown, and personal property did not exist in sufficient quantities to be made the subject of settlement, and consequently conveyancing transactions were few and simple. But the devices of the ecclesiastics to evade the statutes of mortmain, the invention of uses and trusts, and subsequently the passing of the statutes of uses and wills, which enabled the possessor of land to provide for the contingencies which might occur in his family, and to mould his estate according to his whim or fancy, controlled only by the laws from time to time established to guard against the abuse of the privilege, the power of devising real estate, and the multifarious wants of a large and wealthy population, laid the foundation of the system of modern conveyancing. "By means of this system," says a late eminent professor, "there is no device, arrangement, settlement, or disposition which imagination can conceive, or ingenuity construct, which the machinery of the law of England cannot carry into effect with certainty. There is no conceivable purpose to which property may not be applied or rendered instrumental; no event, or combination of events, which can possibly happen in a family, of whatever rank or number, which may not be provided for and met, by a family settlement framed by a master of his art."

Modern conveyancing is conducted on principles which in general are well defined and accurately settled. Of this a remarkable proof was afforded by a statement in Mr. Parke's 'Contre-Projet to the Humphreysian Code,' p. 199, upon the authority of Mr. Preston, that of the cases which came before him (averaging thirty a week), three per cent. only went on to judicial litigation.

The great endeavour, from the earliest times, on the part of the owners of property, has been to be enabled to effect sales and dispositions with secrecy and dispatch, without incurring that publicity which it was the policy of the common law to enforce. Whether it be desirable, for the sake of mercantile credit, to favour secrecy, or promote publicity, in the sale and disposition of property, has been lately much discussed; a general registry has been proposed, and bills for establishing it have been from time to time introduced and thrown out of the House of Commons. [Registration.]

CONVICT. [Penal Servitude; Transportation.]

CONVICTION. [Justice of the Peace.]

CONVOCATION. The assembling of the clergy of the Established Church, in obedience to a writ from the crown, which issues on the meeting of every *new* parliament. In former times, the archbishops, bishops, and the most considerable abbots, were an integral part of the great council of the nation, and as such took their seats with the barons, with whom they were classed. The bishops who now sit in the House of Lords do so by the same prescription. When the burgesses were summoned to assemble by Edward I., to aid in providing supplies for the public service, the inferior clergy were also called upon to do the same, but they objected to do so under the writ of the king, lest they should acknowledge thereby the authority of the temporal power of the sovereign. The expedient was therefore devised of directing the writ to the two archbishops, so that they might compel the clergy to obey their spiritual head. To this the clergy did not object, and thus at this day the two convocations in the provinces of Canterbury and York are wholly distinct and independent of each other; each summoned and controlled by its own metropolitan, to whom alone the suffragan bishops and clergy of each province owe canonical obedience. Thus before, and for some time after the Conquest, matters of Church and commonwealth were often determined in the same meeting, as well by clergy as laity: that is, the chiefs of either being present. But after the course adopted in the reign of Edward I., upon the summoning of the burgesses as a distinct class, and thereby creating the type of our parliament, the archbishops of York and Canterbury, as to them seemed fit, upon cases of emergency summoned their clergy to assemble in convocation of their own mere motion and authority, and such canons or constitutions as were therein determined on were held binding without ratification from the Sovereign on all subject to ecclesiastical jurisdiction, and such custom continued until the statute of Hen. VII. c. 25, s. 19 (commonly called the statute of præmunire) was enacted. On the meeting of every new parliament the archbishops of Canterbury and York, in obedience to the writ from the crown, convoke the bishops of their respective provinces, and the bishops the clergy of their respective dioceses. They meet and proceed, with those who choose to attend (those who do not attend are pronounced contumacious, but the notification of their contumacy is deferred *sine die*), in the province of Canterbury to St. Paul's cathedral, in York to the minster. Prayers are read, and a sermon delivered, both in Latin; the convocation is then, after a few formal matters, adjourned to a future day and to another place; it then meets for the ostensible despatch of business. In the meantime, the inferior clergy proceed to elect proctors to represent them in their own future assembly; they also select prolocutors to communicate with the upper house as occasion may require. In conformity with the two divisions of the legislature, convocation has its upper and lower house; the former composed of the archbishop and bishops of each province, the latter consisting of representatives termed proctors, who are elected from the incumbent clergy. The mode of election varies; in the diocese of London each archdeaconry selects two proctors, and from the collective number so chosen the bishop names two to attend the convocation; in that of Salisbury the archdeacons, three in number, choose six proctors, and those six select two of themselves to represent them: such also is the custom in the diocese of Lichfield and Coventy. In the diocese of Bath and Wells all the incumbents, that is, rectors, vicars, and perpetual curates, have a conjoint voice in the selection. In the diocese of Lincoln, the six archdeacons, through the agency of commissioners, name two persons as proctors. In the diocese of Norwich, the two archdeaconries of Norwich and Norfolk name one proctor, and those of Suffolk and Sudbury the other. The same (*mutatis mutandis*) is the course adopted in the diocese of Chichester. In the province of Canterbury proper, as distinguished from the dioceses comprising the province *in extenso*, the archdeacons represent the clergy. In the province of York, two proctors are returned by each archdeaconry.* Although convocation meets with all the solemnities due to an important body, its functions are practically of little effect; it assembles, it is true, in obedience to the sovereign command, but it is also within the power of the sovereign to command it to discontinue its sitting. In these days, an effort has been made by some of its members to continue its sittings from day to day without prospect of adjournment; but both in Canterbury and York, and more especially in the latter, the archbishops have resolutely defeated the object of those who have been anxious for a continuous session. The act of parliament (25 Hen. VIII. c. 19) subjects to the penalties of a præmunire (that is, *quasi* high treason) any archbishop who summons a convocation without the sovereign's command, or continues to hold it after notice of the crown to cease to do so. Consequently it is generally prorogued from time to time, with little opportunity even for discussion; and, moreover, the convocation itself is so completely under the control of the crown that it cannot pass any canon (that is, any rule or law affecting the clergy, or matters relating to the Church) without a royal licence. Attempts have recently been made to rescue convocation from its present lifeless state, but hitherto without effect; and the assembly of the clerical parliament, for practical purposes, still remains little more than an empty form.

CONVOLVULIC ACID, *Rhodeoretic Acid*, *Hydrorhodeoretin* ($C_{62}H_{54}O_{35}$?). A white uncrystallisable acid, produced by the metamorphosis of convolvulin under the influence of alkalies.

CONVOLVULIN, *Jalapin*, *Rhodeoretin* ($C_{62}H_{50}O_{32}$?). A white gum-like substance, obtained from jalap root. Convolvulin is very slightly soluble in water, insoluble in ether, but soluble in alcohol. Although its alcoholic solution slightly browns turmeric paper, yet it has no basic qualities. It may be detected by its reaction with concentrated sulphuric acid, in which it dissolves with a beautiful amaranth-red colour which disappears after the lapse of some time. Convolvulin is the active principle of jalap, and is highly purgative even in very small doses.

CONVOLVULINOLIC ACID, *Rhodeoretinolic Acid*, *Rhodeoretinol* ($C_{26}H_{24}O_6$?). A colourless crystalline acid, obtained by the action of dilute acids or of emulsion upon convolvulic acid.

CONVOY, in the military service, is a detachment of troops appointed to guard supplies of money, ammunition, provisions, &c., while being conveyed to a distant town, or to an army in the field, through a country in which there is danger that such supplies may be carried off by the peasantry or by parties of the enemy.

In the navy, the name is applied to one or more ships of war which are ordered to protect a fleet of merchant-vessels on their voyage.

CONVULSIONS, irregular (abnormal) and violent contractions of muscular fibres with alternate relaxations. The muscles of the body are divided into two great classes—those which produce the motions necessary for the due exercise of the organic functions, and those which produce the motions necessary for the performance of one of the animal functions, namely, locomotion. The first division comprehends the class of the involuntary, and the second that of the voluntary muscles. Contractility, the property of shortening itself on the application of a stimulus, is the proper function of the muscular fibre; and by this property all vital motion of every kind which takes place in the living system is performed. [MUSCLE, NAT. HIST. DIV.]

The property of contractility is inherent in the muscle; but the manifestation of this property is wholly dependent on the nervous influence; for if the nervous influence be abstracted from a muscle, its fibres are incapable of contracting, whatever degree of stimulus be applied to them. When the muscular fibre is in a sound state, and is supplied with the nervous influence in proper quantity and of proper quality, the fibre contracts with a given degree of force on the application of a certain amount of stimulus. This degree of contraction constitutes its regular or normal action. Contraction, after it has continued a certain time, is succeeded by relaxation; relaxation, in its turn, yields after a given time to another contraction; this contraction to relaxation, and so on successively according to the order proper to muscular action when natural and sound.

But when, on the application of a given stimulus, the muscular contraction is either more violent or more rapid, or longer continued than natural, that is when it does not yield in proper time to the alternate state of relaxation, the muscular action is said to be convulsive, and the disease termed convulsion is induced. The state of convulsion is also produced when the muscular fibre is excited to inordinate action on the application of a stimulus not natural to it. The function ultimately deranged in convulsion is the muscular contractility; but the function proximately deranged is the nervous influence; the manifestation of disease is in the muscular, but its true and proper seat is in the nervous system.

Both divisions of the muscular system, the voluntary and the involuntary, are subject to this irregular and violent action. When the muscles of animal life, or those of voluntary motion, are thus affected, it constitutes the disease called *convulsion* in its true and proper sense; when the muscles of organic life, or those of involuntary motion, are thus affected, the disease is usually termed *spasm*. This distinction is not indeed invariably and universally observed by medical writers; but it would be very convenient if it were so. When the muscle is rigid and tense, and its contraction is persistent, not quickly alternating with relaxation, the contraction or spasm is called tonic; when the contractions rapidly alternate with relaxations, the convulsion or spasm is called clonic. When the convulsive or spasmodic action is of the clonic kind, but instead of being violent is slight, and when very slight contractions rapidly alternate with relaxations, it constitutes what is called *tremor*.

Convulsions differ, first, in kind, as dependent on an excess or a deficiency of vital energy; secondly, in degree; varying from the most powerful, violent, and persistent contractions, without perceptible relaxations, or with relaxations of very short duration, down to the feeblest contractions, with the most rapid alternate relaxations of the slightest tremor; thirdly, in their seat, affecting either the voluntary or the involuntary muscles, or both simultaneously or in succession; fourthly, in their cause, arising from a primary affection of the nervous system, or from irritation propagated to the nervous system from some other part (primary or secondary); fifthly, in their extent, affecting one part separately, or nearly the whole frame simultaneously (local or general); and sixthly, in their character (simple or specific): simple, when unattended with phenomena which give them a determinate type, that is, when the phenomena consist merely of convulsive or spasmodic action; specific, when the convulsive actions pursue a regular and determinate course, and when, moreover, some particular phenomenon is superadded to the series constituting a distinct form or type of disease. In this latter case the disease receives a generic name. The term epilepsy, for example, is given to the disease when the convulsions come on in a peculiar mode, and pursue a determinate course, and when there is present the superadded phenomenon of insensibility or sopor. On the other hand, in the affection called hysteria, the convulsions come on in a different mode, pursue a different course, and are attended with a different but still a determinate train of morbid phenomena. [EPILEPSY; HYSTERIA.]

Voluntary muscles are far more frequently the seat of convulsions, properly so called, than the involuntary muscles. The diaphragm, indeed, an involuntary muscle, next in importance to the heart, is often affected with a proper convulsive action, constituting the disease called *singultus* or *hiccup*; and the heart itself appears to be occasionally affected with a proper convulsive action, in some of the forms of palpitation, for example; but in general, when the organs of the organic life, as the bronchi, the stomach, the intestines, the urinary bladder, the uterus, &c., are attacked with an affection of this kind, it is much more closely allied, as has been stated, to the nature of spasm than of convulsion.

---

* This summary is taken from Mr. Marsden's recently published volumes.

Of the voluntary muscles, whether those appropriated to locomotion, or those destined to act on foreign bodies under the command of the will, and also of certain muscles which, though not under the direct command of the will, still belong to the animal life, having a close relation either to sensation or motion, there is not one which may not be the seat of convulsion, singly, or conjointly with many others.

The muscles of the eyelids, the muscles that move the ball of the eye, the muscular fibres of the iris, the muscles of the face, and more especially of the lips, the muscles of the tongue, the muscles of the pharynx, the muscles of the jaws, and particularly of the lower jaw, the muscles of the neck, the muscles of the chest, back, and abdomen, and the muscles of the upper and lower extremities, may be severally attacked singly or in combination, simultaneously or in succession, with every degree of convulsion, from the most violent tonic contractions to the slightest clonic tremor or twitching. The particular muscles affected, the particular combinations of the muscles affected, the particular order in which the muscular affections succeed each other, may be indicative of specific diseases of the nervous system or of diseases seated in particular parts of the nervous system. The study of these convulsive affections is therefore most important in a practical point of view, as indicating, at one time, the near approach or the actual existence of highly dangerous diseases, having their primary seat in the brain or in the spinal cord; and at another time pointing to no less formidable diseases of the brain and spinal cord excited by diseases of some distant organ. At the same time it should always be remembered that these affections may be purely functional, and not dependent on organic disease at all.

When convulsions attack a single muscle, or a particular set of muscles, the convulsions are called partial or local; when they attack a great number of muscles simultaneously or in rapid succession, they are called general.

The accession of an attack of general convulsion, whether local or general, is commonly, though not invariably, preceded by premonitory signs, which should be carefully looked for, that measures appropriate to the particular nature of the case may be promptly taken to prevent an occurrence of the attack.

In the actual paroxysm, the features of the face are sometimes hideously distorted; the eyeballs are prominent, staring, vacant, wild, and are rolled in every direction; the teeth gnash; the mouth foams; the tongue protrudes; and the action of inspiration from the passage of the air through the clenched teeth, is attended with a hissing sound. So violent are the contractions, that occasionally the teeth, and sometimes even the bones of the extremities are broken by the force. When the muscles of inspiration are involved, and the respiratory function is much obstructed, the face becomes tumid, bloated, and of a dusky or purple colour; and sometimes even the entire surface of the body assumes a leaden hue, from the obstructed circulation through the lungs and the imperfect aëration of the blood. Such is the obstacle to the progress of the blood, that the blood-vessels sometimes give way, and the blood bursts from the nose, or is effused extensively beneath the skin, the effusion probably preventing irreparable mischief to the brain. At other times the face, instead of being red, is pallid and sunk, and then the pulse is feeble, small, and contracted; as in the former case it is full and strong, and attended with a violent beating of the carotids. The violent contractions of the muscles act upon the bladder and rectum, and expel the contents involuntarily and with force. In all the cases in which the current of the blood is much obstructed, the functions of the brain are proportionally impaired, the general sensibility is diminished, and there is sopor, or even coma; at other times consciousness is but little affected, and the violence of the contractions produces severe pain.

The duration of the paroxysm varies from a few minutes to as many hours. The moment the convulsions subside, the patient commonly falls into a long and profound sleep, from which he awakes suddenly, altogether unconscious of what has happened. The attack is generally succeeded by languor, lassitude, sickness, and a disordered state of the stomach.

The paroxysm commonly returns at uncertain intervals, preceded by the premonitory symptoms just enumerated. But sometimes it proves fatal at the very first attack, by producing apoplexy or asphyxia; and not unfrequently it leaves behind it either paralysis or some definite and permanent form of convulsive disease, as epilepsy, chorea, and so on. The frequent recurrence of the fits invariably impairs, and sometimes wholly destroys, the mental faculties.

In some peculiarly nervous and irritable temperaments, instead of the languor and lassitude which ordinarily follow a severe convulsive paroxysm, the exhaustion is so extreme that the patient falls into a state of profound syncope or fainting, which continues for so long a period as justly to excite alarm; and sometimes the patient actually dies in this fainting fit, the brain never recovering its functions. At other times, the animal life is completely suspended, and the action of the organic life appears to have ceased, but the latter is not wholly extinguished, though its functions are performed so feebly as to afford no indication of their existence; consequently, to all outward appearance the patient is dead; yet he may be only in a state of lethargy or torpor, and may ultimately revive.

The preceding account of a paroxysm of convulsion, is the description of it only as it exists in its severest form. In general even the tonic seizure is a much more mild attack; the convulsions being not violent; affecting only a few muscles at a time, and rather passing in succession from one set of muscles to another, than attacking a great number simultaneously. In general too the convulsions are unattended with the obstruction of respiration; are without the abolition of sensation; in short, are without the permanent and dangerous interruption of any function, organic or animal. And more especially when the paroxysm is of a clonic character, the muscles are not rigid, the contractions are not vehement and long-continued, the face is not swollen and livid, but rather pale and sunk, the features are little distorted, the pulse is feeble and rapid, and the extremities are cold.

Convulsions are frequently excited in the progress of other diseases, towards the termination of continued fevers, for example, in which they are almost always of bad, and sometimes of fatal omen; at the commencement of eruptive fevers, as small-pox, measles, scarlet fever, &c., when, though generally indicative of a severe form of disease, they are not so alarming as at the close of continued fever; in inflammatory affections of the brain; in hooping-cough; in cramp; in disordered states of the reproductive organs, and more especially of the uterus, and in long-continued suppression or imperfect performance of the catamenial function.

The causes of convulsions are exceedingly numerous and varied. There is, without doubt, a constitutional predisposition to such affections. They occur far more frequently in the nervous temperament than in any other. The distinctive character of the nervous temperament is muscular mobility combined with nervous irritability. The muscular fibre is relaxed, delicate, and weak; the nervous fibre is peculiarly sensitive, while it is proportionally without energy. Other powerful causes are, peculiar conformation of the body, namely, a feeble frame, with a largely developed head: a relaxed and delicate fibre; a full and plethoric habit; a constitution often manifestly propagated from parent to child; all circumstances capable of producing over-excitement, or in any other mode of inducing debility, physical or mental; an idle and luxurious mode of life; too much indulgence in sleep; neglect of regular and active exercise, and, as would appear, certain electrical conditions of the air, by which the nervous system is rendered more susceptible of impressions, and its vital energy is more rapidly exhausted.

The exciting causes are those which act either upon the animal or upon the organic portion of the nervous system. It has been stated that contractility, though a property inherent in the muscular fibre, can be excited only through the agency of a stimulus derived from the nervous system. All the muscles which are under the control of the will, or which depend on an act of volition for the exercise of their function, derive their nervous stimulus from a particular portion of the nervous system, namely, the spinal cord. Modern physiology has demonstrated that the nervous fibres which supply the stimulus necessary to voluntary muscular motion are different from the nervous fibres which communicate sensation. The first, the motive nerves, communicate with a particular portion of the spinal cord; the second, the sentient nerves, communicate with another portion of the spinal cord. Now, it is found that whatever disturbing influences act immediately upon the motive nerves, or upon that portion of the spinal cord with which the motive nerves are in direct communication, constitute most powerful exciting causes of convulsions. But there is so close a sympathy between the sentient and the motive portion of the spinal cord, and between the spinal cord and the brain, that any disturbing influence which acts powerfully on the one is rapidly communicated to the other. It is indeed seldom that it is possible to trace the seat of the irritating cause either to the motive or to the sensitive portion of the nervous system exclusively; that would imply an accuracy and completeness of knowledge which pathologists are at present far from possessing. All that the present state of knowledge almost ever admits of is to trace the seat of the irritating cause to some portion of the spinal cord or brain; and this, which is nearly all that can be done in any other case, is sufficient to connect the morbid condition of the organ with its disordered function. There are then morbid conditions of the spinal cord and brain which are clearly ascertained to be immediately connected with that disorder of their functions of which convulsions are the result.

Such are, 1. A disordered state of the circulation of the blood through these organs. One of the conditions, the most essential to the due performance of the functions of the nervous system is, that the spinal cord and brain receive a certain supply of arterial blood. If the quantity of blood which flows to these organs be deficient, syncope will be induced, with a diminution or loss of muscular power: of this state convulsions, always of a clonic character, are a constant result. If the blood transmitted to the spinal cord and brain do not circulate through the blood-vessels with a certain impetus and velocity, but be retained either in the capillary arteries or veins, or in both, the state termed congestion [CONGESTION] will be induced, of which convulsions, also in general of a clonic character, are a constant result. If the blood sent to the spinal cord and brain be in preternatural quantity, and if it circulate with preternatural energy, the state of inflammation will be induced, of which convulsions, always of a tonic character, are a constant result. Whether, then, the balance of the circulation be disturbed by deficiency or excess in the quantity of the circulating blood, or deficiency or excess in the motion of it, it will prove alike an exciting cause of convulsions. 2. Precisely the same results are produced if there circulate through the blood-vessels blood vitiated in quality, blood too much venalised, or too much arterialised, or impregnated with poison. The character of the convulsions induced by exciting causes of this class vary essentially according to the nature and extent of the vitiation of the blood and the kind of poison with which it may be imbued. 3. Extravasation of blood upon the surface or into the substance of the spinal cord and brain, by the rupture of the blood-vessels; or the effusion of the serous portion of the blood, occasioning direct pressure on the nervous matter. 4. Organic changes in the constitution of the nervous substance, as a preternatural softening or a preternatural hardening of it. 5. Morbid growths within the nervous substance, forming tumours of various natures and sizes. 6. Mechanical injury of the nervous substance, from the irritation occasioned by the deposition of bony matter on the investing membranes of the nervous substance, or from spiculæ of bone growing out from the inner table of the osseous cases that inclose it. 7. Mechanical violence directly applied to the nervous substance, as from a blow or fall, by which a shock, exhaustive of its vitality, may be communicated to it, or its substance injured, or its circulation disturbed. Such are the more powerful exciting causes which act directly on the animal portion of the nervous system.

But convulsions may be equally induced by the action of an irritating cause on the organic portion of the nervous system. The irritation excited in the organic nerves is transmitted to the communicating branches of the spinal and cerebral nerves, and is by these communicating branches conveyed to the spinal cord or brain. It is in this manner that irritating substances in the stomach or in the intestines induce convulsions, as indigestible or acrid substances taken as food, or acrid matters generated or evolved during the digestive process, or retained by long-continued constipation [CONSTIPATION] in some part of the alimentary canal; or the accumulation of acid, or the presence of worms, &c. Many other noxious agents which act upon one or other of these nervous circles, or upon both conjointly, might be enumerated as the exciting causes of convulsions; but those which have been stated may suffice to indicate the kind of noxious agents which induce this affection, by disturbing the functions of the nervous system.

The treatment in every case of convulsion must be directed to the subduing of the paroxysm and to the prevention of its return. There are certain things proper to be done the instant a person is seized with a fit of convulsions, with a knowledge of which it is desirable that every one should be familiar. The patient should be immediately surrounded as completely as possible with fresh cool air. If he be seized in a small heated and crowded room, circumstances of themselves sufficient to produce a paroxysm in a person strongly predisposed to it, he should be removed into a spacious apartment, the windows of which should be thrown open, and every one whose assistance is not absolutely required should be excluded from the room. In the male, the neckcloth should be immediately untied, and the face, neck, and bosom freely exposed to the air; in the female, the stays should be unlaced, and every thing tight about the body should be removed. If the skin be cool, and the face pallid and sunk, the patient should be placed in the horizontal posture; if the skin be hot and the face flushed, he should be sustained in the sitting or the erect posture, in order, in the former case, to favour the flow of blood to the spinal cord and brain; and in the latter to retard it.

The remedies employed to put an end to the fit must of course depend on the nature of the exciting cause, and on the pathological condition of the nervous system.

COOKING APPARATUS. If cookery be raised to the dignity of a chemical art (and there is no good reason why it should not), we ought to regard cooking vessels as chemical apparatus. It is, however, chiefly in the mode of applying and economising heat, that such apparatus calls forth the exercise of ingenuity.

Of the ordinary cooking vessels we need say nothing; their simplicity has rendered them familiar to all; but of the modern cooking stoves and apparatus, many examples evince skilful arrangement.

In the so-called "bachelor's kettles," of which Spiller's is one specimen, the problem seems to be to determine in how short a space of time, and with how little trouble, can a frugal meal for one person be prepared. Spiller's apparatus consists of a kind of saucepan, with a small opening on one side to admit air, and a flue fixed in the opposite side to let off smoke. A very shallow tea-kettle forms the cover to this saucepan. In the middle of the saucepan is a small iron grating, and on this grating is placed one of those small net-work arrangements of sticks which constitute "patent firewood," and which are now sold so cheaply at one farthing each. This wood being kindled, and the kettle placed over it, the heat is so confined as to make the water in the kettle boil by the time the wood is consumed. With some of these contrivances a kind of small frying-pan is sold; and by using a larger piece of patent firewood, time is allowed for a small dish of savoury cookery after the water has boiled: the kettle being quickly replaced by the pan. There is a certain amount of usefulness in the contrivance which makes it available for others besides the "bachelors" whom the patentee seems to have had in his thoughts.

Many varieties of gas cooking-stoves have been introduced, in which gas jets are made to yield heat sufficient for the processes of boiling, stewing, roasting, baking, frying, &c. Among others is Defries' "Economic Gas Cooking-stove," which is made to suit either large or small culinary wants. Mr. Boggett's gas stoves, for which a patent was taken out in 1850, comprise many varieties, differing from each other chiefly in the mode of making the heat practically available. There is one form called the Liverpool gas-stove, in which separate departments are provided for roasting, baking, broiling, frying, boiling, stewing, and steaming. For many of these purposes the gas is supplied in a ring of jets. On a festive occasion at Exeter, the late M. Soyer cooked a monster joint of meat by means of this apparatus; the meat weighed 565 lbs, and was cooked in a gas oven in five hours, with an expenditure of about five shillings' worth of gas.

The kitchen ranges and other stoves and grates in which coal or coke is burned, are for the most part contrived both for warming apartments and for cooking; but some are designed especially for cooking. The "cottager's stove," manufactured by Messrs. Bailey, of Holborn, consists of a square iron case supported on four legs. Inside this case, and near one end, is a fire-pot, the top of which opens into a flue to carry off the smoke; the rest of the vacant space constitutes an oven; while the top, being flat, is available for many cooking processes. In some of these stoves a boiler is attached to that end which is nearest to the fire. It has been shown that, in one of these stoves, 100 lbs. of meat and 115 lbs. of vegetables, can be cooked with an expenditure of 20 lbs. of coal.

The cooking apparatus of Messrs. Burbidge and Healy is founded on the plans of heating developed by Mr. Sylvester. There are, as in many other similar kinds of apparatus, a large range, an oven, a boiler, a hot-plate, and various subsidiary parts; but its chief features consist in the economising of fuel, and in lessening the amount of radiation sent into the middle of the room. This radiation is an annoyance to the persons present, and involves a loss of some of the heat produced; and it is unquestionably an improvement, other things being equal, if nearly the whole of the heat produced can be applied to the purposes for which it is primarily intended.

Among the many forms of cooking apparatus, that of Mr. Brown is distinguished by having the whole kitchen range, with its oven, boiler, hot-plate, &c., set in a framework which may be placed in any sized fire-place, however large, without setting. The throat, or opening to the flue, is formed in the iron-work of the range itself, so as to be at once determinate in shape and size. With this range is used an automaton roasting jack, arranged in a singular way. In front of the range is placed a sort of semi-cylindrical oven, with the usual hooks and dripping-pans for roasting. A hollow tube projects from the lower part of the oven; and when the oven and range are arranged for cooking, this tube is thrust into an opening beneath the fire-place of the range. While the contents of the oven are exposed to the action of the fire, a current of air is continually drawn through the tube into the oven; and this current sets in rotation a vane-wheel to which the suspended hooks are attached.

Remington's roasting apparatus is, as the name imports, adapted to roasting only. The meat is suspended from or below a jack. There are concave reflectors above and below, which reflect the heat so as to act on the upper and lower surfaces of the meat. The centre of both reflectors is hollowed; the fat which drips from the meat passes through the hollow in the lower reflector into a sort of cup beneath, and is from time to time poured into another vessel, which is perforated and placed over the hole in the upper reflector. The inventor hence calls his apparatus not only a roaster, but a "self-acting baster."

M. Soyer devised a pretty and scientific cooking stove, in which spirit of wine is the fuel used. A lamp is so placed as, by its heat, to boil spirit placed in a vessel above; the steam or vapour of this boiling spirit has no outlet, except through a tube which gradually becomes so narrow as to resemble a blow-pipe; this blow-pipe is placed opposite to a second spirit-flame, and the blowpipe wafts such a constant stream of spirit-vapour into this flame as to heat it greatly, and to make it act rapidly on small cooking vessels placed above it. There is a good deal of chemical ingenuity shown in thus feeding one spirit-flame by vapour derived from another; but the apparatus is somewhat costly.

Mr. Norman has devised a mode of using steam as well as interior radiated heat, in a cooking apparatus. There are two vessels, one within the other, having a space of about three-quarters of an inch between them at top and bottom: this space is partly filled with water. There is a tray for meat, and another tray, perforated, for vegetables, &c. When the vessel is heated, the steam from the water is received by two small pipes, and projected upon the contents of the lower tray; after which, the steam ascends through the perforations to the upper tray.

A lecture delivered at the Royal Institution in 1857, by Captain Grant, of the Royal Artillery, gave much useful information on the important subject of cooking in the British army—a subject to which that officer has devoted considerable attention. Captain Grant draws attention to the much neglected fact, that all stoves or grates imbedded in a mass of brick- or stone-work, occasion great waste of fuel by absorbing some of the heat unprofitably, and by sending a further portion unused up the chimney. The polished steel fittings of modern fireplaces reflect much heat into a room which would otherwise be lost; but unfortunately these costly articles are unattainable by the poor, who are most interested in economy. Hence the detached stoves, whether called Dutch, Brussels, or any other name, render more service than fixed grates, although they may not to an equal degree present the cheerful aspect of an open fire. For cooking, the masonry setting is still more improvident of heat; and it is mainly on this ground that so many portable stoves, gas stoves, steam kitchens, &c., have been introduced.

At the North-West Reformatory in the Euston Road, some of the persons benefitted were employed to construct a cooking stove for their kitchen. It was a detached portable cooking apparatus, in which fuel was used so economically that in 1857 it was found that cooking could be effected for eighty-two persons at a cost of sixpence per day.

The great sufferings of the troops outside Sebastopol, in the winter of 1854-5, from cold, privation, and fatigue, were aggravated by the imperfect arrangements for military cookery. Since that time many improvements have been introduced. On the suggestion of Captain Grant, when Aldershott Camp was first formed, a new kind of cooking apparatus was adopted, primitive in character, but suited to teach soldiers how to cook for themselves more effectively than they have hitherto done. A trench was cut in the ground, and over it was placed a covering of thin iron plates, having a central hole in each large enough to receive an ordinary camp-kettle. A chimney was formed at one end of the trench of sods piled up to the height of three feet; and at the other end of the trench was the fire-place. By this very simple apparatus several regiments cooked their provisions during many months. The next improvement related to battalion cooking-kitchens, when the camp at Aldershott assumed a more complete form. The same principle of the trench was adopted, with modifications; and for two years many of the regiments had their cooking effected in this way. The consumption of fuel requisite for this system is about half a pound of coal per man per day; and the cost is a halfpenny per man per week for three daily meals.

It is a subject for much regret, that English soldiers have never been accustomed to meat cooked otherwise than by boiling. Medical men well know, and on all fitting occasions urge, that this is not the best mode of developing the nourishing qualities of the food. Roasting, baking, frying, and broiling, are processes not adopted in military kitchens in connection with our armies; whereas French soldiers manage to prepare many savoury rations by such means. If soldiers in our barracks wish for a change from the never-varying boiled meat, they club together a few pence, and send their meat to a public bake-house. Captain Grant, like many other intelligent officers, believed that this defect might be overcome by the exercise of a little ingenuity. He has contrived an oven to be introduced in the chimney of his trench-kitchen; and as he makes one chimney serve for two trenches, the oven becomes surrounded by the heated air of two flues. He thus economises heat, and prepares a baked dinner for his men. Without the addition of a single pound of fuel, he found that he could bake 250 lb. at once in a large chimney. So effective is this said to be, that a battalion of a thousand men may be cooked for by two small fires 18 inches square and 6 inches deep.

Captain Grant has still more recently planned a further extension of his simple apparatus, in such form as to enable troops to bake, stew, and steam their food *while actually in the field*. In June, 1859, he made experiments on this subject at Woolwich, in presence of Colonel Tulloh and other officers. The apparatus is fixed to an ordinary four-wheeled advance-waggon, to be drawn by two or more horses, as circumstances might render expedient. The operation of cooking goes on while the vehicle is in transit. A furnace at one end of the apparatus heats the water of a boiler, the steam from which is the chief cooking agent. Steam-pipes communicate from the boiler to a perforated steamer, oven, stew-pan, &c. Each apparatus is calculated to cook food for about 200 men, by means of a very small amount of fuel. The boiler being filled with 120 gallons of water, can have its steam raised in ten minutes, and the cooking can then be conducted while the vehicle is actually in motion. Another apparatus, similar in principle but different in details, has been planned by Captain Grant for making soup instead of cooking joints of meat. It will be an immense boon to the British soldier if these excellent inventions should prove to be as effective in practice as they have been in preliminary trials.

COOLER, COOLING. Various contrivances have been adopted by brewers and distillers for cooling their worts. This has been done by exposing the hot liquor in shallow wooden vessels to the air, and by the use of stirrers or fans to keep the liquor in motion, and thus expose fresh surfaces to the air. The plan has also been adopted of passing spring-water, which in deep wells is usually about 52° even in summer time, through metal pipes placed in the liquor to be cooled.

Wine-coolers are made of porous earthenware, which being soaked in and saturated with water, by its gradual and copious evaporation occasions cold; and in Spain, water-coolers, called *alcarrazas*, are made on the same principle. Coolers of this kind, made of porous clay, lightly baked, and rather thin, are also common in Egypt, where they are often represented on the ancient monuments in a form very much resembling both those now used in Egypt and such as we see in use at Cadiz and other places in the south of Spain. On the monuments of Egypt we sometimes observe a man fanning these earthen vessels with a palm-leaf, in order to promote the evaporation. The Arabs of Egypt are well acquainted with the practice of fanning their earthen vessels to quicken the evaporation. M. Costaz, when in Egypt, made the following experiment on the refrigerating power of these earthen vessels. The thermometer in the shade, but exposed to the air, marked 110°·75 Fahr. during the greater part of the day. At sunset the Nile water was 82°·6; an earthen vessel filled with this water was placed on the deck of the boat in which M. Costaz passed the night on the Nile. At day-break the temperature of the river was the same, but that of the water in the jars was only 61°·25, and more than half of the water was evaporated.

A remarkable mode of cooling liquids was introduced in 1848 by Mr. Lillie of Manchester. It depends on centrifugal force. The liquid is placed in a bowl or colander, either pierced with minute holes all round the sides, or having sides made of wire gauze. Through the intervention of a vertical shaft, this bowl is made to rotate rapidly. The water first rises all round the sides, and then rushes out through the perforations or meshes in a multitude of small streams; these streams, coming in contact either with the ordinary atmosphere in an outer vessel, or still more effectively with artificial currents of air, become rapidly cooled.

Professor Smyth, of Edinburgh University, has suggested a method of cooling the air of rooms in sultry weather. It depends on the principle that air, when compressed, shows a higher temperature than it had before, but resumes its initial temperature on the pressure being removed. The Professor conceived the idea of compressing air, and cooling it while under pressure, in order that, on regaining its original bulk, the temperature should be lower than that of the external air.

COOPERAGE, COOPERING, or the making of casks, barrels, butts, puncheons, hogsheads, tubs, &c., is among the very old mechanical arts. It is supposed that the wine-growers of ancient Italy invented the mode of building up from small pieces of wood vessels which would contain liquids. The coopers of London were incorporated many centuries ago. There is extant a record, under date 1396, in which the Mystery of Coopers applied to the lord mayor for an ordinance, restraining those of the mystery from making vessels for beer or other liquors out of oil- or soap-tuns, whereby the flavour of such beer or other liquors might be injured. This was accordingly ordained. There was another ordinance in 1407, relating to the proper material and workmanship of casks, and to a record of the trade-marks of all the master coopers in London, forty-six in number. By an Act of 1532, brewers were forbidden to make their own casks; and as there is an entry in the books of the Coopers' Company, of a payment of "three pounds, six shillings, and eightpence, for a pipe of Gascony wine that the speaker of parliament had," it has been conjectured whether that curious gift had anything to do with the passing of a statute which threw the whole cask-making trade into the hands of the master coopers of that day.

The trade of cooperage is divided into several distinct branches,—dry coopers, wet coopers, white coopers, general coopers, and back-makers. Dry coopers make the casks for containing sugar, currants, flour, and other dry goods; the work is of a common kind, and is paid for at a low price. Wet coopers make the chief varieties of casks for liquids; the vessels are classed into "large work" and "small work," done by different bodies of workmen. White coopers make tubs, pails, churns, &c., the cleanest and lightest kind of work. General coopers practise all the branches of the trade, without acquiring a high degree of skill in any one. Back-makers, who fabricate the enormous vessels used in breweries, scarcely rank among coopers; they build up pieces of wood in a manner not recognised by regular coopers.

A short description will suffice of each of the above kinds of cooperage.

Small dry work.—Small casks for dry goods are usually made of Quebec oak and of old ship timber. The wood is sawn into lengths, and these into narrower pieces called *codlings*. The codlings are *listed* or chopped with an axe, to make them narrower at the ends than in the middle; and then *cleft* into stave-pieces by a cleaving-knife and a maul. The staves are next *shaved* or *dressed*, a cutting instrument being employed to make them convex on one side and concave on the other. They are then *jointed;* that is, every piece is so shaped on all sides, and from end to end, that all the staves together may make a symmetrical whole, with water-tight joints; in this, the workman relies almost wholly on his accuracy of hand and eye,—an accuracy which nothing but long practice will produce. The cask-heads are usually made of one or two pieces each, properly shaped, and then glued together. By means of temporary circles called *truss-hoops*, the several staves for making one keg are brought together in their proper places, all touching edge to edge at the bulge or widest part, but not yet closed in at the ends. The staves are heated, to enable them to bend without cracking, and the hoops by which they are to be held together are driven on. A groove is cut round the inside of the two ends of the keg, to receive the head and the bottom. The *truss-hoops* at first used are made of iron, and are merely intended to hold the keg together until the head and bottom are put in; they are afterwards removed, and wooden hoops used, made of hazel, birch, willow, ash, or other tough wood. These hoops are bent, notched, and fitted by workmen who carry on this operation alone.

Small wet work.—The smaller casks or kegs for containing liquids differ from those just described chiefly in the greater care necessary; every part is more accurately adjusted, and iron hoops are frequently used instead of wood.

Large dry work.—Large casks for dry goods are made of beech, ash, or oak. The staves are sawn to the proper length; listed or chopped narrow at the ends; slightly dressed or shaved on the side which is to be outwards; jointed or bevelled so as to fit accurately side by side; and thus prepared for building up or putting together. The large casks are more difficult to put together than those of smaller size; but it is done nearly in the same way, by the aid of temporary hoops, within which the staves are adjusted side by side. One man can make a small cask; but it requires two or three to hoop together the staves which are to make a large one. The *chime*, or smooth curved surface of the cask, is produced by a dexterous use of the adze. The permanent hoops, which are to supersede the temporary truss-hoops, are made of birch, hazel, or ash, and are partially prepared before they reach the cooper's hands. The hoops are secured partly by notches and partly by nails.

Large wet work.—Wet work and tight work mean the same thing in the cooper's vocabulary; they refer to the making of casks with the joints so close as to be fitted for the retention of liquids. Rum-puncheons and other kinds of large wet work are made of oak—Quebec, Virginia, Dantzig, Hamburg, or English; the first two are found to be the best for spirit-casks, and the last three for beer-casks. Quebec is the closest-grained, toughest, and most pliable; English is the hardest, most durable, and most expensive to work. The oak is too tough to be split into stave-pieces; it is cut by the saw; and according to the mode in which this sawing is effected, the pieces are called slabbed staves, tongued staves, straight-cut staves, or doublet staves. The successive processes by which a cask is made—the listing, jointing, backing, shaving, head-making, dowelling, firing, trussing, grooving, heading, hooping, &c.—are analogous in general character to those for large dry work, but more precise at every stage, and requiring more skill in the workman. The making of the sides or edges of the staves requires peculiar care. Let it be supposed that a beer-barrel is to be made. Not only must the joints be made so smoothly and accurately that when the staves are brought together they must be perfectly watertight, but as the cask must hold precisely 36 gallons, and as the staves may vary in thickness, the cooper must so manage his exterior curve as to preserve symmetry, and yet retain a uniform internal capacity. The oval casks, which occasionally adorn the bar of a modern gin-palace, are the most difficult part of a cooper's work; two circular casks of different sizes are partially made and taken asunder, and the staves of the larger are so adjusted as to produce the broad sides of the oval, the ends being formed from the staves of the smaller.

White work.—White cooperage comprises open vessels, such as tubs and pails, generally larger at the top than the bottom; and, unlike casks, such vessels are smoothed on the inside as well as the out. The timber mostly employed is either oak or ash. Almost the whole of the cutting is effected by the instrument called a shave, something like the wheelwright's spoke-shave in its mode of action, but used by the cooper in a great variety of different forms. The building up of the vessel requires great neatness of handling; but not so much practised skill is needed as in large wet work, owing chiefly to the circumstance that such accuracy of dimensions is not needed.

Back-making.—The large brewing vessels called backs are thus made: The bottom is usually set up first. The staves are fitted in and pegged to each other, without reference to any particular proportion between them, some being wide at the top and narrow at the bottom, or *vice versâ*. The workman can bring all into symmetry by adjusting the size and form of the pieces last put in. His work is, in fact, carpentry rather than cooperage.

Dock-work.—In addition to the above, there is a kind of cooper's work done at the Docks, to filled rather than to empty casks. Sugar comes over in hogsheads, containing from 1000 to 1500 pounds each. These are thin and slightly made; they are subjected to rough treatment when the sugar is packed into them, and to rougher on shipboard. As a consequence, the hogsheads are distorted in every imaginable way, when landed at the docks in London, Bristol, Liverpool, or elsewhere. It is a custom, perhaps a necessity, that these hogsheads should be brought into something of a symmetrical shape before the sugar is sold to the dealers. This is difficult work to accomplish with the sugar remaining in the hogsheads, for it frequently happens that several of the staves and some of the hoops have been so shattered as to require removal and replacement by new pieces. Casks containing wines and spirits are always examined at the docks, to test their soundness; and any defective places are repaired by piecing. When such casks are landed in such a damaged state as to be unsafe, the wine or spirit is racked into other vessels, and the damaged cask is remade out of the old materials; this is done, not simply to save the expense of new wood, but because the old and well-seasoned wood is less likely than new to impart a bad flavour to the liquor. It is generally rum-puncheons, made by negroes in the West Indies, which require this process of remaking.

When we consider how mathematically exact all the angles and curves must be, cask-making would seem to be a branch of manufacture peculiarly fitted for the application of machinery. Accordingly, we find that patents are frequently taken out for cask-making machinery. Some of these we shall describe.

One patent, by Mr. Brown, obtained thirty years ago, relates to a system of machinery, of which one part cuts the edges of the staves; another part cuts the groove or chime for receiving the head; a third part cuts the head into a circular shape; a fourth bevels the edge of the head; and a fifth gives a smooth circular surface to the exterior of the cask.

Davison and Symington's patent respecting casks, taken out in 1844, relates to the value of a rapid current of heated air, not only in drying wood, but in removing fungous impurities which often accompany damp wood. They recommend that, in making a cask, instead of drying the wood in the ordinary way before using, by which it is difficult to bend without blistering, it should be cut up quite green, and shaped into staves and heads, due allowance being made for shrinkage. The pieces are easily bent in this state, and being temporarily fastened together, they are exposed to a rapid current of heated air, which carries off all the moisture, and shrinks the pieces to the proper size.

The same patentees also use hot air to cleanse casks after using: a method which they consider to be more effectual and cheaper than the use of steam, which is ordinarily employed in the great breweries. In order to remove from the interior of the cask any fungus or impurity which cannot be removed by the heated air, the patentees use a peculiar kind of chain, which enters at the bung-hole, and is worked about by means of machinery.

Mr. Robertson, a cooper of Liverpool, took out a patent in 1849 for a series of machines of rather complicated character, for making casks and similar vessels. One piece of apparatus is intended to plane at one time, both sides of the staves which are to form the curved part of the cask; giving a convexity to one surface and a concavity to the other surface of each piece of wood. A second piece of apparatus planes the edges of the staves, giving to each edge the particular slope necessary for the staves to assume a circular arrangement when placed edge to edge. A third machine compresses all the staves together in a circular form, and forces the ends within the hoops which are to bind them together. Another machine presses together the pieces of wood which are to form the head of the cask, cuts them into a circular form, and bevels the edges. A fifth piece of apparatus cuts the groove in which the head is fitted to the cask; and another punches the holes in the iron hoops. Thus, according to the patentee's plans, every part of a cask is made by machinery.

Mr. Samuel Brown patented in 1840 a mode of making metallic casks. The cask is formed of a parallelogram of sheet iron or other metal, turned up into a cylindrical form, with an ordinary lap joint. The head of the cask is formed of a circular piece of metal, cut out and turned up all round the edge; this being forcibly driven into the cylindrical barrel, has rivets placed at intervals of four or five inches all round, which are rivetted through the barrel and through the turned-up edge of the head. The other end of the cask, called the moveable head, is made like the first, but attached in a different manner; in this case, projecting ears of metal are rivetted at proper intervals around the cylinder; and the heads of these rivets being within the cylinder, serve as stops to prevent the head of the cask from being driven in too far. This second head being forced into its place, the ears are bent down upon the edge of the cylinder, and over the raised edge of the head, thereby retaining it firmly in its place. The joints are to be made fluid-tight with any of the ordinary paints or cements.

In 1852, Messrs. Fox and Henderson devised a mode of making iron casks, for the palm-oil trade; they produced casks 43 inches in length by 38 in bulge, containing 214 gallons each.

In the same year, Messrs. Duncan and Hutton took out a patent for machinery for giving form to the jointing-edges of wood-planks for the staves of casks; producing edges to the pieces for forming the cask-heads; drilling the holes for the dowels used in putting together the heads; giving form to the outer edge or circumference of wood-planks for heads; hollowing and bevelling the ends of the staves; forming the grooves to receive the heads; and putting together.

Perhaps the most complete system of cask-making machinery is that of Mr. Grist, recently patented. It comprises several highly ingenious pieces of apparatus. One is a machine for bending wood to form the staves. The piece of wood to be bent is first saturated with hot water or steam, and is then placed upon the outside of a hollow metal case, shaped exactly as the stave is intended to be shaped; the case is made hot, and a lever, pressing on the piece of wood, keeps it in position until it has permanently acquired the desired form. A second machine gives the proper shape to the edges of the staves. Each stave is held firmly in a frame, and is urged forward at a particular angle to meet a saw and a cutter; the saw cuts the edges of the stave to a right line, and at the proper angle for the radius of the cask, and after this the cutter smoothes or planes each edge. A third machine builds up the staves into the form of a cask. A framework is built up of wood, corresponding on its exterior with the intended dimensions of the cask, or rather, having an expanding and contracting power, to suit it for casks of different dimensions. The staves are placed against this frame, and held there temporarily; after which, truss hoops are fixed on, and the frame and belts removed. A fourth machine performs the operations of chiming and creuzing. The cask, or rather the stave-work which is to form its principal part, is made to rotate horizontally in a lathe, while cutting-chisels or other tools trim the ends in the modes which coopers call chiming and creuzing, to enable the staves to fit into the two ends of the cask. A fifth machine cuts the ends or heads of the casks. The pieces of wood to form the heads and bottom are placed together, and brought under the action of a circular saw, which gives the requisite circular form, and at the same time gives the bevel for adjusting the head to the staves; by a slight adjustment of the mechanism, the head may be made oval instead of round. With two of the shaping machines, one man can shape the edges of the staves for a hundred hogsheads in a day.

Many modes are adopted for cleansing casks which have become foul. They are washed with dilute sulphuric acid, or with a solution of chloride of lime; or are exposed to the mingled fumes of sulphur and saltpetre; or are whitewashed with fresh milk of lime; or are charred by a fire of shavings; or are affected with a sort of charring action by very strong sulphuric acid applied to the wood when perfectly dry; or are exposed to high-pressure steam; or are filled with a mixture of charcoal and water, frequently agitated; or are soaked with a lye of pearlash, lime, or alum. After any of these processes the casks require to be well rinsed with cold clear water.

COORDINATES mean lines, angles, &c. ranged in order. The notion from which the word arose was this, that when the positions of consecutive points on a curve are referred to given points or lines by means of lines (as in ABSCISSA) or angles, those lines or angles present a succession of *arranged* data, by which the several points of the curve may be treated *in order*. It was Descartes who first used coordinates in the second book of his geometry, and the words in which this now all-pervading method of expression was announced are as follows:— "Eligo rectam aliquam lineam, veluti A D, ut ad diversa ejus puncta referam omnia puncta hujus curvæ lineæ C E; deinde eligo etiam punctum aliquod in A B, veluti A, ad *ordiendum* ab eo calculum." We do not find the word in Schooten, Beaune, or others of the immediate school of Descartes. De Witt calls the abscissa *crus patiens*, and the ordinate *crus efficiens*. Coordinates (so called) are used in the writings of John Bernoulli, but in Newton the phrase for them is "lineæ ordinatim applicatæ:" in later times the use of the word has become universal. Coordinates either determine the position of a point in space, or in a plane which is understood to contain all the figure under consideration, as in the first six books of Euclid. They determine position either by straight lines only, or by a straight line and angles: in the latter case they are called *polar* coordinates.

1. Rectilinear coordinates in a plane. In the given plane draw two straight lines meeting in a point O (called the *origin*). From any point P draw parallels to the two lines just named: the parts intercepted between P and these lines (called *axes*) are the coordinates of the point. When the axes are at right angles, the coordinates are said to be *rectangular;* when at another angle, *oblique*. [ABSCISSA.]

2. Rectilinear coordinates in space. Through any point O (the origin) draw three planes which intersect in right angles (the axes). Through any point P draw parallels to the axes: the parts intercepted between P and the coordinate planes (three in number) are the coordinates of P.

3. Polar coordinates in a plane. Choose any point O in the plane, and any right line O A passing through O. Then taking any point P, the distance O P (called the *radius vector*) and the angle P O A (which has no distinct name, but might be called the *vectorial* angle) are the polar coordinates of P.

4. Polar coordinates in space. Choose a plane (M), a point O, and a line O A, in the plane M. Take any point P above or below the plane, and let fall P B, a perpendicular on (M) meeting (M) in B. Then the radius vector O P, and the angles P O B and B O A are the polar coordinates of P. In astronomy, if O be the earth's centre, O A the line passing through the equinox, and (M) the plane of the ecliptic; then B O A is the longitude of P, and P O B its latitude. But if (M) be the plane of the equator, then B O A is the right ascension of P, and P O B its declination.

COPAIBA or COPAIVA, an oleo-resin or turpentine (incorrectly termed a balsam, since it is destitute of benzoic or cinnamic acid), is procured not merely from the *Copaifera officinalis* (Willd.), a native of Venezuela, also naturalised in the Antilles, but from ten to twelve species, chiefly natives of Brazil. It varies in appearance and qualities according to the species from which it has been procured, and likewise according to the age of the tree and the time of the year. Incisions are made in the tree, from which flows a liquid differing little in consistence from thick sap. It is collected in calabashes, after which the incisions are closed with wax or clay. The incisions are repeated in general three times each season. The fluid is brighter or darker in colour, more or less rich in volatile oil, more acrid or more bitter, according to circumstances. It is mostly of a light yellow colour, clear and transparent, seldom turbid or cloudy; odour peculiar, volatile; taste oily, mild, slightly aromatic, at last acridly bitter. Specific gravity 0·966 to 0·997, according to its age. Exposed to heat in a platinum spoon, it is entirely consumed with a white smoke. In a state of purity, it consists of a volatile oil, in the proportion of 40 per cent., and 50 per cent. of an acid crystallisable resin (copaivic acid), with a soft brown resin. The oil may be separated by distillation, or by means of mixing equal parts of copaiba with alcohol of specific gravity 0·837, shaking them diligently, then mixing 100 parts of the copaiva which has been so treated with 37½ parts of a ley of caustic soda, to be again well shaken; after which 150 parts of water are to be thoroughly agitated with it, and the whole left to rest. The specific gravity of the oil thus obtained is 0·900. A slight difference exists between the oil thus procured and that by distillation. Both are used in medicine; indeed the oil is the active principle of copaiva, the resin being of very secondary importance. The oil is destitute of oxygen, and may be employed for the preservation of potassium.

Copaiva is frequently adulterated: the presence of any extraneous matters may be known by the manner in which the suspected portion conducts itself towards solvents and re-agents. Copaiva is occasionally mixed with castor-oil, almond, poppy, nut-oil, and the finer sorts of turpentines. All fixed oils (except castor-oil, the presence of which may be detected by sulphuric acid, but the accuracy of this test is called in question by Brandes) separate from it by being allowed to remain at rest. Good copaiva should be perfectly soluble in alcohol of 90 per cent. It is soluble in all known ethers, and in the volatile and fixed oils. Three parts of copaiva with one of caustic ammonia of specific gravity 0·950 form by agitation a clear soap. The simplest test of the purity of copaiva is to heat a small quantity in a watch-glass, when, if good, a hard brittle resin remains, which has considerable analogy with styracin. The crystals which form in this resin are six-sided prisms, and have the property of polarising light.

A kind of copaiva is obtained in St. Domingo from the *Croton origanifolius* (Lamarck); in Java and elsewhere the juice of the *Canarium commune* (Linn.) is found to possess similar properties. A wood oil from various species of *Dipterocarpus*, especially *D. turbinatus*, is obtained in Moulmein, in the East Indies, and imported into England (Royle).

Copaiva acts as a stimulant to the mucous surfaces, especially of the rectum and urino-genital passages: when the dose is small, it influences the kidney and urethra; but if large, the rectum. It is chiefly used to lessen increased discharges from those organs, and if judiciously employed, generally effects this object; but if given prematurely or in too large a dose, it seldom fails to aggravate the complaints and occasion other serious symptoms. It has likewise been beneficially given in affections of the mucous membrane of the lungs, such as chronic bronchitis, which must be carefully distinguished from true phthisis pulmonalis or consumption, a disease in which it cannot fail to prove injurious. It sometimes occasions a singular eruption, something like measles, and also a swelling of the joints resembling rheumatism.

Various means have been devised to conceal the disagreeable nauseous taste of copaiva without impairing its qualities. Calcined magnesia thickens it, and permits it being made into pills; an etherial or alkaline solution will also retain the virtues, and lessen the repulsive taste.

COPAIVIC ACID. [BALSAMS.]

COPAL, a resin possessed of peculiar properties, the produce of the *Rhus copallinum*, a native of Mexico; it is in rounded masses, smooth and brittle, transparent or nearly so, without colour, or having a slight tinge of yellow: it has but little taste, and is nearly inodorous; it is insoluble in water, fusible, and inflammable. It differs from most other resins in its very sparing solubility in alcohol; and of the little that dissolves with the assistance of heat the greater part is deposited as the solution cools. It is dissolved by ether and some essential oils.

COPAL VARNISH is the substance for which gum copal is chiefly employed. It is probable that every manufacturer has his peculiar mode of proceeding: Tingry prepares the simple copal varnish by heating eight ounces of oil of turpentine in a matrass with the heat of a salt-water bath; as soon as this reaches its boiling point, he gradually throws in an ounce and a half of copal reduced to powder, keeping the vessel in a state of circular motion. This author further states that to obtain this varnish colourless, the rectified oil is to be exposed previously to the sun for some months in bottles, leaving an interval of some inches between the cork and the surface of the liquid; by this the oil undergoes some change, which renders it a better solvent of copal.

The varnish thus prepared is stated to be exceedingly durable and brilliant; it resists scratches, and is susceptible of a fine polish. Tingry particularly recommends it to be applied to philosophical instruments. There are several modifications of this varnish used for particular purposes, as with the addition of oil of lavender and oil of lavender and camphor, an account of which may be seen in the author above named.

The relation which copal bears to other varnishes will be pointed out in a later article. [VARNISHES.]

COPARCENERS. [PARCENERS.]

COPERNICAN SYSTEM. [COPERNICUS in BIOG. DIV.]

COPING, the stone, brick, or plaster cap or covering of a wall, a term perhaps derived from the Italian *coprire*, to cover. Some think it is derived from the German *kopf*, or Dutch *kop*, the head. Coping-stones are placed on the tops of walls to protect them from the weather. Flat coping is called *parallel coping*, and is used upon inclined surfaces, as on the gables and parapets of houses, and also on the tops of garden and other walls. *Feather-edged* coping has one edge thinner than the other. *Saddle-back* coping is thicker in the middle than at the edges. Coping-stones should project over the walls which they cover, and should have a groove or *throating* underneath the projected part to throw off the water. The coping of Gothic battlements and the walls of churches, castles, and dwellings in Gothic architecture, have a deep throating in the form of a bold cavetto in front, and are sometimes decorated with mouldings. [BATTLEMENT.] When the ends of the stones are left higher than other parts, the junctions are called *water-joints*. York stone is much used for parallel coping, and also Portland, but the latter is more expensive and not so durable. Bath stone coping is often used for Gothic works, but it is not calculated to withstand long the constant action of the weather.

COPPER. A well-known metal. It is an element, and is represented by the symbol Cu, an abbreviation of its Latin name *cuprum*.

Copper has been known from the earliest historical ages. It derives its present name from that of the island of Cyprus (Κύπρος) where it was first worked on a large scale. The alchymists called it *Venus*, perhaps on account of the beauty of its lustre, and gave it the symbol ♀, a compound hieroglyphic indicating that they thought it a mixture of gold, ☉ and a certain hypothetical substance called acrimony ✠, the corrosive nature of which was symbolised by the points of a Maltese cross.

Copper occurs native, and as the base of numerous ores. Its mineralogy has already been treated of and the ores described in detail, under COPPER, in NAT. HIST. DIV. The source of commercial copper is principally *copper pyrites*, a double sulphide of copper and iron (Cu_2S, Fe_2S_3). It occurs abundantly in Cornwall, two-thirds of the copper annually smelted in Great Britain, having a value of nearly one million sterling, being obtained from the ore raised in that county. More valuable but far less abundant ores are the *red oxide* (Cu_2O), *black oxide* (CuO), *malachite* a green carbonate, and *azurite* a blue carbonate.

The metallurgy of copper or copper smelting, is a branch of manufacture extensively conducted in the neighbourhood of Swansea, South Wales, a locality peculiarly fitted for the operation on account of its proximity to the coal-fields, and its position as a sea-coast town; these advantages at all times insuring cheap fuel and cheap freightage to the different metallurgical establishments.

The ore of copper as raised from the mine is first cleaned from adhering portions of the strata through which the vein passed, then sorted according to quality, so far as appearance indicates, and placed in heaps of convenient size for sale. To ascertain the value of a heap, a fair average sample is taken, and about four hundred grains of it assayed by roasting, fluxing with borax, reducing with black flux, &c., according to the nature of the ore: or a weighed quantity may be dissolved in nitric acid, excess of ammonia added, the mixture filtered, boiled with caustic potash or soda, and the resulting oxide collected on a filter, washed, dried, ignited, and weighed; 100 parts will contain 79·82 of copper. As both the composition of copper ore and its richness in metal are liable to great variation, the methods of smelting are necessarily complicated in order that these variations may be met. The process, however, on which the modifications are all based, is a very simple one. It consists first in roasting the ore on the hearth of a powerful reverberatory furnace; any arsenic is thus driven off, whilst a portion of the sulphur is converted into sulphurous acid and escapes, oxygen taking its place. The iron present in the ore, however, has a greater affinity for oxygen than the copper has, and hence the sulphide of iron will be decomposed before the sulphide of copper. As soon as the sulphide of iron is thus oxidised the roasting is discontinued, and the oxide of iron removed by fusion with sand or siliceous ore, and sometimes a little fluor spar. The sulphide of copper is now partially roasted into oxide and then fused, when an interesting reaction occurs, the sulphide and oxide mutually decompose each other, sulphurous acid escapes and metallic copper remains; the decomposition is expressed in the following equation :—

$$\underbrace{CuS}_{\text{Sulphide of copper.}} + \underbrace{2CuO}_{\text{Oxide of copper.}} = \underbrace{SO_2}_{\text{Sulphurous acid.}} + \underbrace{Cu_3}_{\text{Metallic copper.}}$$

The metal thus produced is again roasted to remove the last traces of foreign matters, and is finally thoroughly deoxidised by heating with carbonaceous materials, and especially by the operation of *poling*; in which a pole of green wood, generally birch, is thrust into the molten metal and rapidly moved about; the powerfully deoxidising gases given off from the wood effectually reduce the oxide, and when a small sample taken from the mass, and tested when cold by partially cutting through and then breaking, presents a fine fibrous fracture and a satiny lustre, the operation is considered to be complete, and the metal is at once ladled out and cast into ingots. Great care and considerable experience are necessary to detect with certainty this latter point, as a few minutes *overpoling* would determine the formation of carburet of copper; and this would render the whole mass brittle and necessitate re-roasting.

Such is an outline of copper smelting. For an elaborate description of it in all its details, see Muspratt's 'Chemistry, applied to the Arts and Manufactures,' pp. 493 to 532.

Perfectly pure metallic copper may be obtained on the small scale by decomposing a solution of sulphate of copper by means of the voltaic battery, or by inserting strips of iron into the same solution; in the latter case the precipitated metal is called *cement copper*. Another method consists in strongly heating six parts by weight of the pure oxide with one part of finely powdered charcoal and a little borax; in this way a button is at once obtained. Copper in a state of fine division results, when a current of hydrogen gas is passed through the pure oxide heated to redness.

Copper has a characteristic red colour; very thin films of it however, such as are frequently obtained by the chemist in analysing organic substances by the aid of black oxide of copper, appear by transmitted light of a beautiful green colour, though by reflected light they also have the usual tint. Copper is rather hard, sonorous, and exceedingly ductile and malleable. Its specific gravity varies from 8·78 to 8·96, according to the manipulation to which it has been subjected; it is one of the best conductors of heat and electricity, and expands one part in 582 on being heated from 32° Fahr. to 212°. Copper crystallised in the form of cubes or octohedra is occasionally found native. It may be obtained in the same state artificially by slow voltaic action. The melting point of this metal is under that of gold, but higher than silver; in the fused state it exhibits a bluish-green colour, and at an intense white heat, such as is produced by a powerful electric current, or the oxyhydrogen blowpipe, it boils, burns with a green flame, and is entirely volatilised.

Copper does not tarnish on being exposed to dry air, but in the presence of moisture and carbonic acid, it gradually becomes covered with a greenish coating of oxide and carbonate. Nitric acid rapidly attacks and oxidises copper, forming a nitrate of copper. Sulphuric acid does not act upon it when cold, but at a boiling temperature oxidises it with evolution of sulphurous acid and formation of sulphate of copper. Hydrochloric acid acts only on copper in the presence of oxidising agents. The fixed alkalies act but little on the metal, ammonia in the presence of a small quantity of air gradually dissolves it, forming a colourless solution of suboxide; more air causes the formation of a deep blue solution of protoxide. Copper has a nauseous styptic taste, and on being rubbed emits a peculiar disagreeable odour.

The equivalent of copper is 31·75.

Copper and *oxygen* unite in four different proportions :—

	Formula.	Equivalent.
Suboxide of copper	Cu_2O	71·5
Protoxide of copper	$Cu\ O$	39·7
Binoxide of copper	$Cu\ O_2$ (?)	
Cupric acid	(?)	

1. *Suboxide of copper* (Cu_2O); *cuprous oxide, dinoxide*, or *red oxide of copper*. This oxide occurs native in the form of beautiful red crystals. It is best prepared artificially by heating a solution of sulphate of copper with excess of caustic potash or soda and a little honey, the suboxide deposits in the form of bright red granular crystals.

The salts of this oxide are very unstable, and consequently difficult of preparation,

Sulphite of cuprous oxide and potash is formed by gradually adding solution of sulphate of copper to a hot solution of sulphite of potash; on cooling the salt deposits in crystalline needles. The principal use of suboxide of copper is in the staining of glass, to which it communicates a ruby-red colour.

2. *Protoxide of copper* (CuO), *black oxide*, or *cupric oxide*, prepared either by heating copper-plates and turnings in a current of air, or from the nitrate of copper, by heating that salt to redness in an earthen crucible. By the former method it is obtained more or less massive and crystalline, by the latter in the state of fine powder. In either condition it is used to some extent by chemists in the analysis of organic substances. [ORGANIC ANALYSIS.] It is also used to stain glass of a beautiful green colour.

The salts of protoxide of copper are numerous, well-defined, and important. The following are the principal of them.

Sulphate of copper (CuO, $SO_3 + 5$ Aq.), equiv. 124·7, *blue vitriol*. This salt occurs native, see BROCHANTITE, NAT. HIST. DIV. It is obtained as a by-product in silver refining; also in large quantities in the roasting of copper pyrites at a temperature approaching low redness; this heat is sufficient to decompose the sulphate of iron formed at the same time, but is not high enough to affect the sulphate of copper. It is purified by crystallisation from a hot aqueous solution. It may also be formed by boiling copper with three times its weight of strong sulphuric acid, diluted with one-third its weight of water; the copper is oxidised at the expense of part of the sulphuric acid, and combines with the remainder. Commercial sulphate of copper is, however, principally manufactured by simply dissolving the crude oxide or scale in sulphuric acid with the aid of heat. The scale is obtained by roasting waste copper, and in the process of annealing copper-plates; it consists of a mixture of metallic copper with oxide.

Sulphate of copper crystallises in large blue crystals of an oblique rhombic form. It is soluble in two parts of boiling water, from which solution one half of the salt crystallises out on cooling. Heated, it loses its water of crystallisation, assumes a white colour, and at a higher temperature is decomposed, the acid being expelled and the oxide left.

Sulphate of copper is largely used in calico-printing, and in the manufacture of pigments. Large quantities of it are also employed in agricultural districts to steep seed-corn in, it being found that this is an effectual remedy against the disease in wheat called "smut." For the latter purpose, however, a very impure sulphate of copper is frequently used; obtained by evaporating the Birmingham "pickle," or "dipping liquor," of the brazier and coppersmith. This liquor is an acid solution into which manufactured brass articles have been dipped in order to render them perfectly clean before lacquering, varnishing, &c. The sulphate thus obtained costs some shillings less per cwt. than the purer variety, but more of it must be used to produce the desired effect.

Double sulphates of copper and alkali, are obtained by evaporating a solution containing equivalent proportions of the separate sulphates. The potash salt contains $(CuO, SO_3 + KO, SO_3 + 6\ Aq.)$ the ammonia salt $(CuO, SO_3 + NH_4O, SO_3 + 6\ Aq.)$, the soda salt $(CuO, SO_3 + NaO, SO_3 + 2\ Aq.)$; the latter is rather difficult to prepare. Double salts may also be formed with the sulphates of several other metals.

Ammonio-sulphate of copper $(CuO, SO_3 + 2\ NH_3 + HO)$ separates in dark blue crystals on cautiously evaporating a solution of sulphate of copper to which excess of ammonia has been added. Anhydrous sulphate of copper absorbs ammoniacal gas, yielding a compound consisting of $(2(CuO, SO_3) + 5\ NH_3)$.

Nitrate of copper $(CuO, NO_5 + 6\ Aq.)$. Prepared by dissolving copper in nitric acid; the following decomposition occurs:—

$$\underbrace{Cu_3}_{\text{Copper.}} + \underbrace{4NO_5}_{\text{Nitric acid.}} = \underbrace{3(CuO, NO_5)}_{\text{Nitrate of copper.}} + \underbrace{NO_2}_{\text{Nitric oxide.}}$$

By evaporation of the solution it is obtained in beautiful blue rhomboidal prisms. They rapidly deliquesce in the air, and are very soluble in water or alcohol.

Carbonate of copper is not known in the neutral state. Associated with hydrated oxide it occurs native. [Copper, in Nat. Hist. Div.] When solutions of a salt of copper and an alkaline carbonate are mixed, a bulky, gelatinous, green precipitate falls, usually having the composition $(CuO, CO_2 + CuO, HO)$. Under various names it is used as a pigment. [Colouring Matters.] Mixed with lime and exposed to the air its colour is changed to blue.

Acetate of copper $(CuO, C_4H_3O_3 + HO)$, *verditer*. Prepared by dissolving oxide or subacetate of copper in acetic acid and evaporating the solution. It crystallises in oblique rhombic prisms, and is soluble in five parts of boiling water.

Subacetates of copper. [Acetate, *Diacetate of Copper.*]

Arsenite of copper $(2CuO, AsO_3)$; *Scheele's green*. Precipitated on mixing solutions of arsenite of potash and sulphate of copper. It is extensively used as a pigment. If acetate of copper be employed in the place of sulphate the precipitate contains $(CuO, C_4H_3O_3 + 3(2CuO, AsO_3))$, and is known as *Schweinfurth green*. The different *arsenical greens*, as these pigments are called, owe their different tints to the various proportions of acetate and arsenite of copper contained in them, and also occasionally to the presence of carbonate of copper. [Colouring Matters.]

Protoxide of copper combines with many other acids, but the compounds formed are comparatively unimportant.

Hydrated protoxide of copper (CuO, HO) is precipitated when an alkali is added to an aqueous solution of any copper salt.

3 *Binoxide of copper* (CuO_2)? is a brownish-yellow powder, formed on treating hydrated protoxide of copper with peroxide of hydrogen. At a slightly elevated temperature it loses one half of its oxygen. On account of its liability to change it has been but little studied.

4. *Cupric acid ?* said to contain more oxygen than either of the preceding oxides, is supposed to be formed when finely divided copper, caustic potash, and nitrate of potash are together heated to redness. Digested in water, the mass yields a blue solution that disengages oxygen on being slightly warmed.

Copper and *hydrogen* form

Hydride of copper (Cu_2H). It is obtained as a brown hydrate, very unstable, when hypophosphorous acid is added to a solution of sulphate of copper heated to 140° Fahr.

Copper and *nitrogen* form

Nitride of copper (Cu_6N). Obtained on passing ammoniacal gas over oxide of copper heated in an oil-bath.

Copper and *sulphur* form two sulphides.

5 *Disulphide of copper* (Cu_2S) is produced when copper is burnt in vapour of sulphur. It melts more readily than metallic copper, and forms a semi-crystalline mass on cooling.

Protosulphide of copper (CuS) is precipitated of a black colour when sulphuretted hydrogen is passed through a solution of a copper salt. Washed and dried, it presents a very dark green appearance.

Double sulphides of copper and other metals are found native. [Copper, Nat. Hist. Div.]

Copper and *chlorine* form two chlorides, corresponding to the oxides and sulphides.

Dichloride of copper (Cu_2Cl), Boyle's *resina cupri*, is obtained in transparent tetrahedra on boiling the protochloride and metallic copper together in close vessels. Heated it fuses and then volatilises. In contact with air it quickly absorbs oxygen. It is but little soluble in water. Its aqueous solution is used in gas-analyses for the absorption of carbonic oxide.

Protochloride of copper $(CuCl + 2Aq.)$ is most easily formed by dissolving the oxide or carbonate in hydrochloric acid. On evaporation transparent, bright green, right-angled four-sided prisms are obtained. They are very deliquescent.

Oxychlorides of copper, of variable composition, are obtained on precipitating chloride of copper with a caustic alkali.

Double chloride of copper and ammonium $(CuCl, NH_4Cl + 2Aq.)$ crystallises on the cooling of a solution of the mixed chlorides in equivalent proportions.

Cuprammonium, in the state of *chloride*, is by Graham and Kane considered to be the true constitution of a compound containing (H_3NClCu), obtained on passing ammoniacal gas (NH_3) over chloride of copper heated to a temperature of about 400°. They regard this salt as simply chloride of ammonium (NH_4Cl), in which one equivalent of hydrogen is replaced by an equivalent of copper.

Copper and *iodine* form only one compound,

Diniodide of copper (Cu_2I). A light brown powder, precipitated on mixing together solutions of sulphate of copper, sulphate of iron, and iodide of potassium—

$$\underbrace{2(CuO, SO_3)}_{\text{Sulphate of copper.}} + \underbrace{2(FeO, SO_3)}_{\text{Protosulphate of iron.}} + KI = \underbrace{KO, SO_3}_{\text{Sulphate of potash.}} + \underbrace{Fe_2O_3, 3SO_3}_{\text{Sesquisulphate of iron.}} + \underbrace{Cu_2I}_{\text{Diniodide of copper}}$$

Copper and *bromine* form two bromides,

Dibromide of copper (Cu_2Br) is produced when metallic copper is heated in vapour of bromine.

Protobromide of copper $(CuBr)$ is obtained in crystals somewhat resembling iodine in appearance, on evaporating in vacuo a solution of hydrated protoxide of copper in aqueous hydrobromic acid.

Copper and *cyanogen* combine to form two simple cyanides,

Dicyanide of copper (Cu_2Cy) falls as a white powder on adding cyanide of potassium to a solution of dichloride of copper in a little hydrochloric acid. It is soluble in ammonia, dilute acids, and alkaline cyanides.

Protocyanide of copper $(CuCy)$. A brownish-yellow compound, precipitated on mixing solutions of sulphate of copper and cyanide of potassium. It is very unstable.

Double cyanides of copper and other metals, or *cuprocyanides*, are described under Cyanogen.

Alloys of copper. [Alloy; Brass; Britannia Metal; Bronze; German Silver.]

Tests for the Salts of Copper.—The most characteristic are the following: *Ammonia* in excess forms a dark blue solution. *Ferrocyanide of potassium* yields a fine red-brown precipitate. A strip of bright *metallic iron*, in a slightly acid solution of a copper salt, has, after a short time, copper deposited on it with characteristic colour. *Before the blowpipe*, on a charcoal support, copper compounds furnish in the reducing flame, with carbonate of soda, a bead of metal recognised as copper by its colour.

Estimation of Copper.—In addition to the processes, for the quantitative determination of copper, mentioned at the commencement of this article, the following volumetric method is recommended by Mr. E. O Brown: Ten grains of the matter under examination are placed in a half-pint flask and dissolved in boiling diluted nitric acid; carbonate of soda is then added till a precipitate is formed, and lastly, excess of acetic acid. About sixty grains of iodide of potassium are now introduced, and sufficient time having been allowed to elapse for the crystals to dissolve, a standard solution of hyposulphate of soda is poured in from a burette till the brown liquid assumes a yellow colour. A little clear solution of starch is then added, and the addition of the hyposulphite of soda continued until the blue iodide of starch has entirely disappeared.

In the above process care should be taken that the iodide of potassium is free from iodate of potash, and that the acetic acid contains no sulphurous acid. The solution of starch should be dilute and rendered clear by standing. The solution of hyposulphite of soda is made by dissolving 4000 grains of the salt in two gallons of water, and standardising by means of electrotyped copper.

COPPER, in a metallic state, produces no action on the human system. When in the form of oxide its action is considerable, though variable, being dependent on the kind and quantity of acid which it may meet with in the stomach; but all its salts occasion peculiar effects, which may be fatal if the dose be large. It is not necessary that the substance should be introduced into the stomach, for the salts of copper act in whatever way they are introduced into the system, and the more energetically the more directly they enter the blood. The greater the degree of solubility, the more rapidly are the formidable symptoms displayed. The chief preparations of copper used in medicine are, the sulphate, or blue vitriol, called also blue-stone; the ammoniated sulphate or ammoniuret; and the diacetate, or verdigris. The two former are used internally, the latter externally; it and the sulphate being applied by surgeons to wounds and sores in particular states.

Sulphate of copper influences powerfully the nervous system, and acts as a tonic and antispasmodic; it has also some astringent properties. Nevertheless, it often promotes free secretion of saliva, which renders it an eligible tonic in some forms of dyspepsia, with depressed nervous power, when a dry condition of the mouth and throat exists, particularly in the morning. It is often available in such cases when mercury is inadmissible. The presence of a minute quantity of copper in Saidschutz water may render that spring a preferable place of resort for dyspeptics in whom torpor of the liver prevails. In a considerable dose the sulphate causes vomiting; in still larger doses it causes purging, accompanied with tenesmus, followed by convulsive agitation of the head, or rigidity amounting to tetanic, laborious respiration, pain and tightness of the head, insensibility, lethargy, and speedy death. In some instances the narcotic symptoms are the first to be displayed, those of irritation succeeding; jaundice, if the patient survive, or yellowness of the corpse, is no uncommon occurrence,—a fact to be borne in mind as a distinctive mark of poisoning by copper among metals: the same sign however occurs in poisoning from aconite, and most ranunculaceous plants. If the effect of the poison when copper has been taken has been speedy, few traces of morbid action are found in the intestinal canal; and "too much reliance ought not to be placed on mere bluish or greenish colouring of the membranes of the stomach; for Orfila and Guersent have both observed that the inside of the stomach, as well as its contents, may acquire these tints in a very remarkable degree in consequence of natural disease." (Christison.)

In cases of slow poisoning by copper, such as happen when some of its salts in substance or solution have been taken daily for a considerable time, fatal results follow, and the copper may be detected accumulated in the liver, though not discoverable in any other organ of the body. The circumstances of the copper being carried to the liver explains the frequent occurrence of jaundice, as stated above.

In small medicinal doses, sulphate of copper has been employed in diarrhœa, which, when chronic, it often checks; even in Asiatic cholera it has proved useful. Indeed it seems to check augmented secretion from all mucous surfaces, on which account it may be used in chronic discharges from the urino-genital organs, and also of the lungs, to benefit which last organ it is usually given as an emetic. It may likewise be employed as an emetic in cases of poisoning by narcotic agents, in preference to tartrate of antimony or ipecacuanha, as its action is not preceded by nausea, which promotes the absorption of the poisonous agent.

Its chief internal use, however, is as a tonic and antispasmodic, in many convulsive and nervous diseases, such as epilepsy and chorea. In these last-named diseases the ammoniacal sulphate is often to be preferred, given in the form of pill. Sulphate of copper is, however, in most frequent use by surgeons as an external application to wounds when indolent, or filled with the unhealthy kind of granulations termed "proud flesh." It is similarly used in some forms of ophthalmia, especially of the inner surfaces of the eyelids. Small ulcers of the gums readily heal by touching them with the *Melægyptiacum*, a solution of sulphate of copper in honey.

Diacetate of copper is rarely given internally; but it is the frequent source of accidental or intentional poisoning, when its general effects are nearly the same as those of the sulphate. In the form of a liniment, it is of great utility in certain affections of the mouth and gums, applied by means of a camel's-hair brush. Likewise as an ointment to stimulate old and indolent ulcers, it is superior to all other means.

Poison often results from the formation of verdigris in copper vessels used in cooking, or the more reprehensible practice of putting copper coins into pickles to make them a fine green colour. It seems that copper vessels, if kept clean, are not dangerous, provided whatever is boiled in them (unless of an acid nature, which will always form some dangerous compound) be not allowed to stand to cool in the vessel, but be instantly poured out. Tinning the interior of copper vessels affords protection so long as the tinning remains entire. In case of poisoning, the best antidotes are whites of eggs, milk, or wheat flour; ferrocyanate of potass, or iron filings, in gum-water, may be given; sugar or any syrup is useful. But liver of sulphur should never be given, and least of all should vinegar.

COPPER, ALLOYS OF. [Copper.]

COPPER MANUFACTURE. In the article above the processes are noticed of smelting and refining copper, whether it be intended for the manufacture of brass, or rolling into sheets. Here we shall briefly notice some of the subsequent processes in the manufacture of copper goods. It may be well first, however, to notice one or two additional matters relating incidentally to the smelting.

Great Britain is not so rich in copper as to give it a leading position among copper-producing countries; it is the advantage of cheap fuel, and the skill obtained by our smelters, that render the operations in Cornwall and Wales so important. It is also observable that France and Belgium are almost destitute of copper-mines; so that the English have an opening in those countries for manufactured copper, and can compete in Central Europe with Russian copper. It has sometimes been feared that the large supplies of copper from Chili, the United States, and Australia, will by-and-by affect injuriously the Cornish interest; but, on the other hand, if processes be adopted for the more economical reduction of copper, ores of two qualities could then be brought into the market. South Wales, although not yet materially threatened, is beginning to feel the effects of competition further north. Liverpool, having a great import of foreign and colonial copper ores and bar copper, is favouring the establishment of smelting-works on the Mersey; and now that great port has a copper-market which is growing yearly in importance. Many of the South Wales smelters from time to time bring forward improvements in their art; one, for instance, is that of Mr. Parkes, relating to processes for obtaining superior copper from inferior ores, by adding a little iron or zinc, which is afterwards driven off. The ore is smelted as usual, so far as the roasting process; the ore is then allowed to cool; one cwt. of iron is thrown in to 50 cwt. of regulus; the furnace-doors are closed; the whole is heated up to the degree of pimpled copper, and then tapped. Mr. Parkes also has a process for the treatment of argentiferous copper-ore, depending on the fact that silver may be volatilised by applying heat when in combination with metallic zinc and arsenic.

Leaving any further details untouched in this article, we proceed to notice the modes of fabricating sheet and bar copper into useful articles.

The principal peculiarity in the manufacture of this metal arises from the facility with which it may be fashioned by the hammer. The processes of casting and rolling, both of which are extensively practised in the manufacture of copper goods, so closely resemble the like operations upon other metals, that they do not require further notice; but the operations of the copper-smith are very distinct from any other branch of metallic manufactures. One of the best examples, perhaps, of manufactures in copper, is presented in the large pans for boiling sugar in vacuo; and this we may take to illustrate the successive processes. Each of these pans consists of a circular domed vessel, with several apertures for valves, gauges, &c., and a spiral coil of copper pipe within the lower part. The top and bottom of this vessel, which are of similar shape, both being convex externally, are formed of one piece each, in the following manner: The copper is in the first place cast into a form resembling that of a double convex lens, thickest in the middle, and diminishing gradually towards the edges. This lens is then subjected to the powerful blows of a tilt-hammer, directed more continuously near the centre than near the edges. A little consideration will show that this hammering, while it reduces the thickness of the copper, must make it curl up at the edges, or assume a dished or hollow form: we find that this is the case even when a flat piece of metal is hammered at its centre, and still more does this result ensue when an increased substance is given to the centre. The thickness of the centre is so adjusted as to afford metal enough for the curvature of the vessel, and the hammering is continued till the thickness of the whole is brought nearly uniform. This is a very important process, since the fitness of the vessel for the operations of the sugar-refinery depends on the soundness and perfection of the metal. Sometimes a piece of copper, dished or hollowed in this way, and worth forty guineas in material and labour, if sound, is rendered useless by a flaw in the metal.

The above description will indicate the mode in which many curved articles of copper receive their shape. Another process no less peculiar to the manufacture is the hammering, technically called *planishing*, by which the metal is rendered dense and firm, and its toughness is increased,—a process of so deafening a nature as to impart a singular character to a coppersmith's establishment. This operation presents something of the picturesque effect formerly observable in anchor-smitheries, when Nasmyth's hammer had not yet superseded the ordinary hammers: six or eight men, standing in a circle round the piece of copper, and each wielding a heavy hammer, strike the metal in succession, every part of the surface receiving probably as many as ten or twelve blows. Any one who examines a large copper vessel will perceive, both in the hammer-marks and in the density and close grain of the surface, evidences of the planishing process.

By these two processes of hammering, the first to beat the copper into the required shape, and the second to condense and harden the surface when the shaping is completed, many articles which it might seem difficult to form without numerous joints are fashioned, often from masses of cast metal formed originally in a very different shape, or very much smaller and thicker than the finished articles are intended to be. In many cases, however, the hardness occasioned by the hammering impedes the shaping process, and must be repeatedly removed by annealing or softening by heat, to renew the malleability and extensibility of the metal. The principal component parts of a large copper vessel being thus formed, the next point which claims notice is the mode of joining them together. *Riveting* is a mode of fastening much employed for this purpose. In this process the edges of the adjoining plates are made to overlap, and holes are punched through the overlapping plates by a punching-engine, which cuts out a small circular piece equal in size to the rivet. The rivets, which may be compared to short, thick, blunt nails, are then inserted; and the smaller ends, which project through the holes, are spread out by the hammer so as to form what may be styled a second head. The edges of the sheets or plates of copper are finally *caulked*, or hammered until they close so perfectly as to form a joint impervious to water, air, or steam. Smaller copper vessels are united by soldering or brazing. Holland, in Lardner's 'Cabinet Cyclopædia,' refers to a copper tea-kettle as presenting a familiar but ingenious specimen of the coppersmith's art, both with reference to soldering and hammering. "Taken, indeed," he observes, "in all its parts, it exhibits the result of almost every operation of his workshop." To make this article a piece of sheet copper is taken, rather longer than the intended circumference of the kettle, and some inches wider than its depth. The surface of this piece of copper, for about an inch at each end, is then brightened by filing, and one end is cut into to the depth of about an inch, and at intervals of about an inch, with a pair of shears. Every alternate portion of the cut edge is then turned a little back, so that when the plate is bent round into a cylindrical shape, the uncut end may be laid between the alternate tongues or portions of the cut edge, and embraced, as it were, by them. A mixture of borax and solder is then applied to the joint, which is, after soldering, hammered upon a steel mandril or stake, until the seam becomes smooth, and is beaten down to the thickness of the adjoining portions of the plate. A perfect cylinder being thus formed, the next operation is to turn it inwards in a sloping direction for a space of about two inches, to form the top of the kettle, or that portion which extends from the shoulder at the top of the cylindrical side of the vessel to the edge of the opening to which the cover is fitted. This is done by hammering upon an anvil of suitable shape. About an inch of the lower end is then turned inward in the same way, and cut with the shears into tongues, which are bent back alternately in the same manner as those at the end of the plate had been. A piece of sheet copper cut to fit the end of the cylinder, so as to form the bottom of the kettle, is then inserted and united to the cylinder by the same process as that described for the first joint. The vessel is then *pickled* in diluted sulphuric acid, after which it is planished to brightness, the marks of the hammer being rendered imperceptible by the intervention of a piece of old moreen, or other woollen stuff, between the surface of the copper and the stake or anvil on which it is laid. The lid of the kettle is dished by stamping it in a die; the handle is cast; and the spout, after being soldered up and rounded a little on a mandril, is finally shaped upon lead with which it has been filled, and afterwards soldered or riveted into its place. Copper tea-urns and saucepans are formed by soldering and hammering in a similar manner, the former being in general finished with a beautiful colour, produced by the application of sulphate of copper or Roman vitriol, previous to the planishing or burnishing.

There are several different modes of forming copper piping out of sheet metal. In one of these, the edges of the sheet, which is curved round a mandril, are made to meet without overlapping, and united by hard solder; in a second, they overlap, and are united by soft solder; in a third they overlap, and are secured by rivets; in a fourth, the edges are folded together, one being bent outwards and the other brought over it and turned into the acute angle formed between the outside of the tube and the turned back edge, the whole being subsequently made close and firm by hammering; while in a fifth, both edges of the pipe are turned back and covered with a strip of sheet metal, the two edges of which are turned in like the outer edge of the joint last described. The bending of such pipes into curved forms, as for the spiral coil in the sugar-pan described above, is a curious operation. Any attempt to bend such a tube while empty would be certain to impair its shape, and would probably occasion its fracture. To obviate this difficulty the pipe is, before bending, filled with lead, or some soft metallic alloy which will melt at a temperature which will not injure the tube. Being thus filled, the pipe may be treated as a solid bar of metal, and safely bent into any required form by suitable machinery; and when the desired curvature is gained, sufficient heat is applied to cause the contained metal to melt and flow out of the pipe. A patent was taken out a few years ago, for a mode of using up old worn-out rollers, such as those employed in calico-printing. The cylinders are to be bored truly, rolled or drawn out to the form of tubing, and annealed.

The use of copper sheathing for ships, an application which occasions a very large demand for this metal, is alluded to under SHIP-BUILDING. The articles BRASS; BRONZE; and BELL-CASTING, treat of some of the most important manufactures of the alloys of copper. Of some of the minor articles of manufacture, in the composition of which copper forms a chief constituent, an account is given under BUTTON; and COCK.

We add a few words concerning the trade and statistics of copper. No effective attempt has ever been made to ascertain the actual productiveness of the mines in this country; and all that is hitherto known on the subject is derived from partial inquiries of individuals. By this means, however, a tolerably accurate account has been taken of the produce of the copper mines in Cornwall, reaching back to 1771, with the exception of a few intermediate years, the returns of which are wanting. Since 1821 similar accounts have been procured of the produce of other mines in the United Kingdom. The annual produce of the Cornish mines rose from about 3400 tons in 1771, to 5000 tons in 1800; 7000 tons in 1820; and 12,000 tons in 1835. Since the last named year the yield has not advanced in equal ratio. The total quantity of metallic copper obtained at the smelting works of England and Wales, was 14,000 tons in 1835; since which year there has been a steady increase.

The supply from South Australia is becoming important. It was in 1845 that twelve miners began operations at the Burra Burra copper-mines in that colony; in the beginning of 1859 there were more than a thousand employed, supporting a population of five thousand persons. In the intervening period of fourteen years, the Burra Burra yielded 128,000 tons of copper ore, from which 26,000 tons of metallic copper were obtained, worth from two to three millions sterling, according to the state of the market. A small portion of the produce was shipped to England in the state of ore.

During the last three years, the imports of copper ore and regulus into Great Britain have been as follows, from different countries :—

	1856.	1857.	1858.
	Tons.	Tons.	Tons.
From Spain	5,692	13,030	6,122
,, Cuba	19,836	16,352	14,728
,, Chili	33,227	39,295	48,329
,, Australia	8,434	8,489	9,128
,, All else	15,614	17,928	18,792
	82,803	95,094	97,099

Including copper in a partly manufactured state, the total in 1858 amounted to 128,280 cwts. The exports of metallic copper, in the same three years, presented the following figures :—

	1856.	1857.	1858.
	Cwt.	Cwt.	Cwt.
Brick and pig copper	121,935	142,920	134,618
Sheet and nail copper	287,571	274,536	303,810
Wrought copper	28,716	65,419	58,114

This is irrespective of the copper contained in the articles of brass manufactured. The declared value of the copper and copper goods exported in 1858, was no less than 2,698,836*l.*, averaging about 109*s.* per cwt. British India is the largest purchaser of these goods.

COPPER-NICKEL. [NICKEL.]

COPPERAS. [IRON, *Protosulphate of.*]

COPPICE, a wood or plantation of various kinds of trees, which shoot up from the root when cut down, and which are periodically cut down before they acquire any considerable size. The most common trees planted or used for this purpose are the oak, the chestnut, the maple, the birch, the ash, and the willow. The hazel and the alder are also frequently planted in coppice, the former in dry and chalky soils, the latter in moist and marshy situations. Timber trees are generally allowed to grow in coppice, or more properly the coppice is the underwood where the timber is the principal object. There is a doubt, however, whether it is judicious to allow many trees to stand where there is a ready sale for coppice wood. The quick return of the latter overbalances the greater price of old timber. In consequence of this opinion, large trees fit for ship-building, which require a long time to arrive at the required size, are becoming scarce; and many woods, once thickly studded with majestic trees, are reduced to mere coppice wood. The value of a well-managed coppice is considerable where the produce can be readily manufactured into useful articles, and carried to a good market. Ash hoops, hop-poles, chestnut gate-hurdles, and sheep-hurdles are the principal articles manufactured or prepared in a newly-cut coppice. What is of no use for these purposes is made into faggots for fuel, where this is scarce, or converted into charcoal, which is more easily transported. A good coppice will bear to be cut down every eight or nine years, and will thus be worth, according to situation, from 6*l.* to 15*l.*, per acre, or even more, when sold to those who undertake to cut and prepare the wood.

Little attention is generally paid to the coppice, except when it is fit to be cut, but this is a great mistake: with a little attention a coppice may be doubled in value in a few years. It should be carefully drained where the water has not a ready outlet. Where the most profitable kinds of wood are deficient fresh plants should be supplied. The whole should be kept well stocked, but not overstocked; and the pruning-knife should be used where it appears necessary, especially where hop-poles are in request, which usually bear a good price. Hop poles require a longer time to attain the proper size, and more room to grow. For this purpose the coppice may be thinned out, without being entirely cut down. When a coppice is cut, attention must be paid to the manner in which the poles and rods are cut off from the stem. They should be divided by a clean slanting cut with a very sharp axe or bill-hook, so as not to shatter the stump which is left. The wound will then soon heal over, and the stump will not be injured by the wet and decay, as is too often the case. When fresh ground is planted for a coppice, it should always be previously trenched and drained. The extra expense of this will soon be repaid. Scotch firs may be planted at first as nurses and shelter to the oaks and other forest trees. In seven or eight years the firs will have acquired a considerable height, and may be thinned out or cut down; they never shoot again from the root. The other trees may be left to grow a few years longer, before they are cut down. After the first cutting, attention must be paid to the stumps and all superfluous shoots removed. In seven or eight years a thick coppice will be formed, which will increase in value every time it is cut, and will produce a very good annual rent for land which might not have been profitable in cultivation, either as pasture or arable farms. The annual expense of a coppice is trifling, and the regular returns are certain and profitable. When a portion of coppice is cut every year, so as to have a regular rotation, the income is as regular as that of any other part of an estate. A proportion of coppice on an estate is essential to the production of game and to its preservation.

The ground most favourable for coppice is that which is too steep or rocky for cultivation, and where the climate will not allow of the vine. Where the land is flat, and can be well drained, arable farms will always be most profitable, unless in some poor sandy soils, where corn will not grow without extraordinary manuring, while the roots of some kinds of trees will sink to a great depth and find there the nourishment necessary to their growth. In such sandy soils the birch, the maple, and the acacia sometimes grow luxuriantly, when the grass on the surface scarcely shows signs of vegetation. On wet and boggy soils the willow and the alder are almost the only trees that will thrive. Whoever plants a coppice must be well acquainted with the soil to a considerable depth, and must choose his plants accordingly.

COPT, the name given to the Christian descendants of the ancient Egyptians. It is correctly pronounced either Ckoobt or Ckibt, and it is generally believed that the name is derived from Coptos, once a great city in Upper Egypt, now called Ckooft or Gooft, to which, during their persecution by the Roman emperors, many of the Egyptian Christians retired. We are inclined to recognise in *Copt* the main part of the ancient name of the country *Αἴγυπτος*. The name *Copts* seems to have been used as the common designation of the Christians in Egypt from the time of the Emperor Heraclius, when the patriarch Benjamin was permitted to return from his exile in the Thebais (about A.D. 644) and to resume his functions as a bishop at Alexandria. (Le Quien, 'Oriens Christianus,' ii. 481.) They are not an unmixed race, their ancestors in the earlier ages of Christianity having intermarried with Greeks, Nubians, and Abyssinians. The secession of the early Christians of Egypt from the Church of Constantinople occasioned bitter enmities to spring up between them and the Greeks, on which account they suffered so much persecution, that they united with the Arab invaders of their country to expel the Greeks; but though their revenge was gratified, they were compelled to bow to a heavier yoke. With the exception of a small proportion who profess the Romish or the Greek faith, the Copts are Christians of a sect called Jacobites, Eutychians, Monophysites, and Monothelites, whose creed was condemned by the council of Chalcedon, A.D. 451. The number of churches and convents in ruins prove that the Copts were once far more numerous than at present: they do not now compose more than one-fourteenth part of the population of Egypt, their number not exceeding 150,000, about 10,000 of whom reside at Cairo. Conversions to the Mohammedan faith, and intermarriages with the Moslems, have occasioned this decrease in their numbers; to which may be added the persecutions which they endured from their Arabic invaders and subsequent rulers. They were forced to adopt distinctions of dress, and they still wear a turban of a black or blue, or a grayish or light brown colour, in contradistinction to the red or white turban. The distinction is generally carefully observed in the towns, but less so in the villages. Under the dominion of the recent Pashas of Egypt, the Copts are not the despised race they once were: some of them have even been raised to the rank of beys. The male adults pay a tribute, besides the income tax which they pay in common with the rest of the inhabitants; but they are exempt from military service. This immunity is the result of Moslem prejudice.

In some parts of Upper Egypt there are villages exclusively inhabited by the Copts, and in every village of moderate size is a Mo'al'lim (a title given to all Copts except those of the poor class or peasants), who keeps the register of the taxes. Most of the Copts in Cairo are employed as secretaries and accountants, or tradesmen; they are chiefly engaged in the government offices; and as merchants, goldsmiths, silversmiths, jewellers, architects, builders, and carpenters, they are generally considered more skilful than the Moslems. In the villages they are employed in agriculture, like the rest of the peasantry. The patriarch or head of the Coptic church, judges petty causes among his people in the metropolis, and the inferior clergy do the same in other places; but an appeal may be made to the cadi. A Moslem aggrieved by a Copt may demand justice either from the patriarch or cadi, but a Copt who seeks redress from a Moslem must apply to the cadi. The Copts are somewhat under the middle size. They are extremely bigoted, and bear a bitter hatred to all other Christians; they are of a sullen temper, extremely avaricious, great dissemblers, ignorant, and faithless. In their habits they scarcely differ from their fellow-countrymen. Their dress, with the exceptions already noticed, is similar. The women veil their faces, according to the custom of the country. The Copts frequently indulge in excessive drinking; but in their meals, the mode of eating, the manner in which they pass their hours of leisure, which is chiefly in smoking their pipes and drinking coffee, they resemble the other inhabitants of the country. The women, however, though closely veiled when out of doors, like the Turkish women, eat at the same table with their husbands and family, unveiled, even in the presence of strangers; and the priest has unrestricted access to them for the purposes of confession.

The Coptic hierarchy consists of a patriarch, a metropolitan of the Abyssinians, bishops, arch priests, priests, deacons, and monks. The patriarch is styled "Patriarch of Alexandria," but generally resides in Cairo. He is usually chosen by lot, and always from several monks of the convent of St. Anthony, in the Eastern Desert, who are nominated by the superior. He continues to observe the monastic regulations, one of which is to remain unmarried. The metropolitan of Abyssinia, who always resides within his diocese, is appointed by the patriarch, and retains his office for life. The number of bishops is twelve, who are generally chosen from the monastic order. The arch-priests are numerous, and selected from among the priests. The priests are required to be of the age of thirty-three years at the least, and are not permitted to marry, though they may have married before taking the priesthood; but if the wife dies they cannot marry again; and the widow of a priest is not allowed to marry a second husband. The priests are supported only by alms and by what they obtain by their own industry. A deacon must be either a person unmarried, or have been only once married to a virgin bride. By taking a second wife he loses his office. The monks undergo a severe novitiate, and take the vow of celibacy. The churches contain ill-executed and gaudy pictures of various saints, but no images are admitted. The number of Coptic churches and convents is said to amount to 146, but the former are few in comparison with the latter. The form of service is not characterised by much solemnity, and the conduct of the priests is often somewhat indecorous. The marriage ceremony is performed either by a priest, or without his assistance by mutual consent before witnesses; and divorces are as easily to be obtained by either party as with the Mussulmans. Baptism is practised under a belief that if the ceremony be omitted the child will be blind in the next world. The children are generally circumcised; but in Cairo the custom is less strictly observed than in other parts of the country. Confession is required of all members of the Coptic church, and is indispensable before receiving the Lord's supper. Wednesday and Friday are observed as fast-days, except during the fifty days immediately following the Great Fast. The seven great festivals are as follow:—the Nativity of Christ, Baptism, the Annunciation, Palm Sunday, Easter, the Ascension, and Whit-Sunday. The Copts are not allowed by their church to intermarry with persons of any other sect.

(*An Account of the Manners and Customs of the Modern Egyptians, written in Egypt during the years* 1833, 1834, and 1835, by Edward William Lane; *Reise in den Orient*, by Konstantin Tischendorf, Leipzig, 1846.)

COPTIC LANGUAGE, the language spoken and written by the inhabitants of Egypt since the introduction of the Christian religion into that country; and distinguished from the more ancient Egyptian language, which was in use under the Pharaohs and the Ptolemies. What was the relation of the ancient to the more recent language of Egypt, we are unable to determine, as our information respecting the former is very imperfect. Egypt lost much of its consequence when it became a Roman province; and when Alexandria ceased to be a royal residence, arts and literature would naturally fall into decay. Another cause which proved fatal to Egyptian literature was the early introduction of Christianity into Egypt. This event which contributed to extend the study of Greek literature and the use of the Greek language, at the same time deprived the ancient literature of the country, as chiefly connected with the old religion, of the better part of its interest. Notwithstanding these unfavourable circumstances, the language of the country continued in ordinary use, particularly in the interior provinces. Many hermits in the desert of Thebais, and many bishops of Upper and Lower Egypt, knew no other language; and the Egyptian, or as it is more appropriately called during these later times, the Coptic language survived for seven or eight centuries after the conquest of Egypt by the Arabs, but it gradually gave way to the Arabic, which is now the language generally in use throughout Egypt.

The literature extant in the Coptic language is by no means rich. The only part of any intrinsic value seems to be the Coptic translations of the Bible, probably made towards the close of the 3rd and in the beginning of the 4th century, and following, as far as the Old Testament is concerned, the Septuagint version, the readings of which, as well as those of the Alexandrine text of the New Testament, they may serve to determine. Of the prophets Isaiah, Jeremiah, Ezekiel, and Daniel, Dr. Henry Tattam published an edition, with a parallel Latin version, in 1852. Besides these, there exist Coptic translations of sermons from the Greek fathers, fragments of the decrees of councils, likewise generally translated from the Greek, liturgies, acts of martyrs, original mystic treatises on ethics, with numerous examples from the lives of pious hermits, and translations from the Greek of some apocryphal books of the New Testament.

Such as we find it, the Coptic language exhibits evident traces of the fate of the country in which it was spoken. Under the Ptolemies, and afterwards under the Romans, new forms of government and administration were introduced into Egypt; and the inhabitants necessarily borrowed from their conquerors the names of public offices and other terms relating to political matters. The Coptic language received a further supply of foreign words in consequence of the introduction of Christianity. A great number of Greek words were retained in the Coptic versions from an apprehension, as it seems, of profaning the Christian doctrine by venturing to translate expressions deemed peculiarly holy in the Greek original text. It has been remarked, that the proportion of Greek expressions is not the same in all Coptic writings; and that only few occur, for which equivalents might not be found among the genuine Coptic words.

It is well known that the ancient Egyptians, besides the hieroglyphics, possessed an alphabet or syllabic system of writing of their own. In the modern Coptic we find the Greek alphabet employed, with eight new letters added to it, to express certain articulations peculiar to the Copts. It is uncertain at what period the Greek alphabet came into use.

Athanasius, bishop of Kous, in an Arabic treatise on the grammar of the Coptic language, a manuscript of which is preserved in the Royal Library at Paris, informs us that there were three dialects of Coptic; namely, the dialect of Misr or Upper Egypt, commonly called the Sahidic; the Bahiric, so denominated from Bahirah, or Lower Egypt, and usually called the Memphitic; and the Bashmuric, spoken in the district of Bashmur, in the Delta. In the Bahiric, or Memphitic dialect, as well as in the Sahidic, we possess manuscripts of nearly the whole of the Bible and of the services of the Coptic church, besides some other less important works; but in the Bashmuric dialect only a few fragments have hitherto been discovered and published. The character common to all these dialects is that of a language which, having lost its original power of expressing by grammatical inflection the relations of notions in sentences, has, like most other modern languages, resorted to particles and auxiliary words to supply that deficiency. The precision with which these auxiliary words are employed, and the extent to which they can be combined in forming derivative words, are remarkable, and may well be compared with the use of letters and other symbols in an algebraical formula. The plural of nouns is distinguished from the singular by a monosyllabic prefix; the genders of substantives are seldom marked by a peculiar termination, but are determined either by the article, or by the addition of a word implying "male" and "female." There are no terminations of case; and all changes of declension must be expressed by means of particles. There is a definite and an indefinite article. The definite article has in the singular distinct forms for the masculine and feminine genders, but does not distinguish the gender in the plural; the indefinite article admits of a distinction of number only. The degrees of comparison are expressed by subjoining auxiliary words to the adjective, which is unalterable. The personal pronouns are almost the only part of speech that has preserved some traces of inflection: besides these, the Coptic has separate forms for the possessive, demonstrative, the relative, and the interrogative pronouns, and has pronominal suffixes and insertions (infixes) which are applied to nominal and verbal inflexions. Ordinal numbers are formed by prefixing various auxiliary words to the cardinal numbers. The verb has only an active voice, and the passive must be expressed by circumlocution, usually by the third person of the plural (as in Latin, *ferunt* = *fertur*, or in English, *they say* = *it is said*.) The imperative generally exhibits the root of the verb in its pure state. The conjugation of verbs is accomplished by adding pronominal prefixes to the root, which vary to a certain extent in the different tenses; if a verb in the third person singular is preceded by a relative pronoun, its pronominal prefix is usually dropped; there are no participles in the strict sense of that term. The number of prepositions in the Coptic language is considerable.

Of the three dialects, the Memphitic, Sahidic, and Bashmuric, the first appears to be the most polished. The Sahidic has admitted a greater number of Greek expressions. Words which in Memphitic end in *i*, have in Sahidic *e* for their termination. The Sahidic substitutes the sound *h* for the Memphitic *kh*, and the tenues ϖ, κ, τ, for the aspiratæ θ, χ, ϑ, also sometimes *oo* for ω, and *sh* for *j*. The Bashmuric agrees with the Sahidic in preferring the tenues ϖ, κ, τ, to the corresponding aspiratæ, and *h* to *kh*; moreover, it substitutes the vowel *a* for the Memphitic *o*, and *e* for the Memphitic *a*, *ei* often for *i*, *au* for ω, *b* for *f*, and particularly *l* for *r*.

(Henry Tattam, *A Compendious Grammar of the Egyptian Language*, London, 1830, 8vo, and *Lexicon Ægyptiaco-Latinum*, Oxford, 1835, 8vo; Am. Peyron, *Lexicon Linguæ Copticæ*, Turin, 1835, 4to; Quatremère, *Récherches Critiques et Historiques sur la Langue et la Littérature de l'Egypte*, Paris, 1808, 8vo; Dr. G. Parthey, *Vocabularium Coptico-Latinum et Latino-Copticum e Peyroni et Tattami Lexicis*, Berlin, 1844.)

COPULA, a name given in logic to the affirmation *is*, or the denial *is not*, by which the subject and predicate of a proposition are connected, as in "Man *is* mortal," "Every man *is not* perfect." In the usual system of logic no other copula is permitted: thus, "Man *has* reason," would be expressed as "Man *is* a being having reason." [PROPOSITION; RELATION.]

COPYHOLD, a term in English law applied to lands held by what is called tenure by copy of court roll, the nature of which is thus described by Littleton (§ 73, 4, 5), "Tenant by copy of court roll is as if a man be seised of a manor, within which manor there is a custom which hath been used time out of mind of man, that certain tenants within the same manor have used to have lands and tenements to hold to them and their heirs in fee-simple or fee-tail, or for term of life, at the will of the lord, according to the custom of the same manor. And such a tenant may not alien his land by deed, for then the lord may enter as into a thing forfeited unto him. But if he will alien his land to another, it behoveth him after the custom to surrender the tenements in court into the hands of the lord, to the use of him that shall have the estate. And these tenants are called tenants by copy of court roll, because they have no other evidence concerning their tenements, but only the copies of court rolls." From this it appears that the title to copyhold lands is not only modified but altogether constituted by custom; subject to the estates in them which the custom confers they are held by the lord under the common law as part of the demesnes of his manor. For these customary estates were in their origin mere tenancies at will, though by long indulgence they have in many instances acquired the character of a permanent inheritance descendible (except where otherwise modified by custom) according to the rules of the common law; and as tenancies at will they continue to be considered, in all questions relating to the *legal*, as distinguished from the customary property in the land.

The origin of copyholds is involved in great obscurity. The opinion generally adopted among our lawyers and antiquarians, and supported by the authority of Littleton, Coke, Sir Martin Wright, and Mr. Justice Blackstone, is, that copyholders have gradually arisen out of the villeins or tenants in villeinage who composed the mass of the agricultural population of England for some centuries after the Norman conquest, through the commutation of base services into specific rents either in money or money's-worth. ('Co. Litt.,' 58a—61a; Blackstone's 'Com.,' ii., p. 89, Dr. Kerr's ed.; Wright, 'On Tenures,' 3rd edit., p. 215; Hallam's 'Middle Ages,' vol. iii., p. 254.) [VILLEINAGE.]

Although the revolution in the condition of these classes of persons was accomplished gradually, it seems in the middle of the 13th century to have begun to assume a more decided character. There are proofs of as early a date as the reign of Henry III. of a limitation of the services of villeins to certain specified acts which were recorded in the lord's book. The descendants of persons so privileged began to claim a customary right to be entered on the court roll on the same terms as their predecessors, and, in process of time, prevailed so far as to obtain a copy of the roll for their security. It is said in the year-book of the 42nd of Edw. III. to be "admitted for clear law that if the customary tenant or copyholder did not perform his services, the lord might seize his land as forfeited;" which seems to imply a permanent interest in the copyholder, so long as he performed the services. This view of the law is confirmed by Britton in a passage cited by Lord Coke ('Co. Litt.,' 61a), and was adopted by the judges in Edward IV.'s time, who held that a copyholder might maintain an action of trespass against the lord for dispossession.

The two great essentials of copyhold tenure, according to Blackstone, are: 1. That the lands be parcel of and situate within that manor under which they are held; and, 2. That they have been demised or demisable by copy of court roll immemorially. "For immemorial custom," says that author, ii., p. 94 (Dr. Kerr's Ed.), "is the life of all tenures by copy; so that no new copyhold can, strictly speaking, be granted at this day."

The burdens to which a copyhold tenure is liable, in common with free tenures, are fealty, services, reliefs, and escheats; besides which it has certain liabilities peculiar to itself in the shape of heriots and fines. A heriot is the render of the best beast or other chattel (as the custom may be) to the lord on the death of a tenant.

Of fines, some are due on the death of a tenant, and others on the alienation of the land; they are sometimes fixed by the custom, sometimes arbitrary; but in the latter case it is an established rule of law that the lord cannot demand by way of fine upon the descent or alienation of the land more than the amount of two years' improved value of the property, after deduction of the quit-rents to which it is liable. The ordinary mode of alienating a copyhold estate in fee-simple is by *surrender and admittance*, which is effected in the following manner:— The copyholder appears in court, and professes to surrender or deliver up his land to the lord (either in person or, which is more usual, as represented by his steward), expressing the surrender to be to the use of A, and his heirs; and thereupon A is *admitted* tenant of the land to hold it to him and his heirs at the will of the lord according to the custom of the manor. He then pays a fine, and also (if required) does fealty. All these circumstances, or at least the surrender and admittance, are entered on the court rolls; and the new tenant, paying his fees to the steward, receives a copy of this fundamental document of his title. Surrenders are made in various forms, as by the delivery of a rod, glove, or other symbol, to the steward or other person taking the surrender. Surrenders may also be made to the lord in person out of court; to the steward; and by special custom to the lord's bailiff; to two or three copyholders, or into the hands of a tenant in the presence of other persons. When a surrender is taken out of court, it may be, and formerly must have been, presented by the homage or jury of copyholders at the next general court, except where a special custom authorised a presentment at some other court; but by a recent statute, 4 & 5 Vict., c. 35, s. 90, presentment is now no longer essential. Admittances also may be made out of court, and even out of the manor.

The words in the admittance, "to hold at the will of the lord," are characteristic of those customary estates to which the term copyhold is in ordinary legal language exclusively appropriated, in contradistinction to what are sometimes called "customary freeholds" (which estates are very common in the north of England), and ancient demesne lands. These are all included under the term copyhold in the Statute 12 Car. II. c. 24, which abolished all the old tenures in England except common soccage, copyhold, and some other specified tenures. Though customary freeholds and ancient demesne lands for the most part pass by surrender and admittance, the admittance is expressed to be "to hold according to the custom of the manor."

The Statutes of Wills (32 Henry VIII. c. 1, and 34 & 35 Henry VIII. c. 5) do not include copyholds, and therefore formerly it was necessary in order to enable a person to dispose of copyholds by will that he should first have surrendered them "to the use of his will," as it was called. This ceremony was rendered unnecessary by the Statute 55 Geo. III. c. 192, which, however, does not extend to customary freeholds; but the Wills Act (1 Vict. c. 26) extends the power of disposition by will, without surrender to the use of the will and even before admittance, to customary freeholds and all customary or copyhold estates whatsoever. A devise of copyholds by will might formerly have been made without observing the formalities prescribed by the Statute of Frauds (29 Car. II. c. 3), the terms of that statute not extending to copyholds; but the requirements of the Wills Act (1 Vict. c. 26) must now be complied with. The Statute of Entails (13 Ed. I.), commonly called the Statute of Westminster the 2d, does not extend to copyholds; but in most manors a custom of entailing copyholds has prevailed. These entails might formerly be barred by a proceeding in the Lord's Court, analogous to a common recovery, or, in the absence of a custom authorising such a proceeding, by a mere surrender. And now by Statute (3 & 4 Will. IV. c. 74, § 50–54 inclusive) entails of copyholds may be barred by assurances made in pursuance of the provisions of that Act. It is a general rule that no statute relating to lands or tenements in which those of a customary tenure are not expressly mentioned, shall be applied to customary estates, if such application would be derogatory to the customary rights of the lord or tenant. Hence neither the provision in the Stat. of Westm. the 2d (13 Ed. I. c. 18), rendering debtors' lands liable to process of execution by writ of elegit, nor the Statute of Uses (27 Henry VIII. c. 10), nor the Statute of Partition (31 Henry VIII. c. 1, and 32 Henry VIII. c. 32), nor the Statute enabling persons having certain limited interests in lands to grant valid leases (32 Henry VIII. c. 28), nor any of the local Registry Acts, were applicable to copyholds.

Until a recent period copyholds could not be seized upon an outlawry, nor were they assets for payment of specialty debts at law, nor were they even liable for debts due to the crown, although they were always subject to sequestration under the decree of a court of equity. But copyhold lands belonging to traders were subjected to the operation of the bankrupt laws (v. stat. 6 Geo. IV. c. 16, sec. 68 and 69); and by Stat. 3 & 4 Will. IV. c. 104, copyhold lands of all persons whatever which have not been devised for payment of debts, are rendered assets to be administered in a court of equity for the payment of specialty and simple contract debts. Copyholds are not liable (except by special custom) to the incidents of curtesy or dower. The latter, where authorised by the custom, is called the widow's "free bench." These estates being considered continuations of that of the deceased tenant, are perfected without admittance. A purchaser or devisee of copyholds has an incomplete title until admittance; but the customary heir is so far legal owner of the land *before admittance* that he can surrender or devise it, or maintain an action of trespass or ejectment in respect of it. The lord may by a temporary seizure of the land compel an heir or devisee to come in and be admitted; and he is himself compellable by a mandamus of the Court of King's Bench to admit any tenant, whether claiming by descent or otherwise.

By the general custom of all manors, every copyholder may make a lease for any term of years, if he can obtain a licence from the lord, and even without such licence he may demise for one year, and in some manors for a longer term, and the interest thus created is not of a customary nature, but a legal estate for years, of the same kind as if it had been created out of a freehold interest. But every demise without licence for a longer period than the custom warrants, and in general, every alienation contrary to the nature of customary tenure, as a feoffment with livery of seisin, is followed by a forfeiture to the lord. A copyhold estate may also be forfeited by waste; as by cutting down timber, or opening mines, when such acts are not warranted by the custom. In the absence of such special custom, the general rule seems to be that the right of property both in trees and mines, belongs to the lord, while only a possessory interest is vested in the tenant; but neither can the lord without the consent of the tenant, nor the tenant without the licence of the lord, cut down trees, or open and work new mines. In like manner forfeiture may be incurred by an inclosure or other alteration of the boundaries of an estate, refusal to attend the customary courts, or to perform the services, or to pay the rent or fine incident to the tenure. The 9th section of the 1st Wm. IV. c. 65, protects infants, lunatics, and married women from the last mentioned cause of forfeiture. In case of felony or treason being committed by a copyholder, the lord has the absolute benefit of the forfeiture, unless it has been expressly provided otherwise by Act of Parliament. In all cases of forfeiture the lord may recover the forfeited estate by ejectment, without prejudice to the rights of the copyholders (if any there be) in reversion or remainder. He may waive the forfeiture by a subsequent act of recognition of the tenure. If he does not take advantage of the forfeiture for twenty years, his right to do so is barred by the Act for the Limitation of Actions, 3 & 4 Wm. IV. And if he neglect to take advantage of the forfeiture in his life-time, his heir cannot avail himself of it.

The lord may also become entitled to a customary tenement by escheat for want of heirs. Formerly where a copyhold was surrendered to a mortgagee and his heirs, and no condition was expressed in the surrender, and the mortgagee died intestate and without an heir, the lord was entitled to enter for escheat. To remedy this, the 13 & 14 Vict. c. 60, repealing 4 & 5 Wm. IV. c. 23, which contained a provision with a similar object, enacts that where a trustee or mortgagee of lands of any tenure whatsoever, dies without an heir, the Court of Chancery may make an order vesting such land in such persons, and for such estates as the court shall direct.

If the lord (having acquired a copyhold tenement by forfeiture, escheat, or surrender to his own use) afterwards grant it away by an assurance unauthorised by the custom, the customary tenure is for ever destroyed. And if he makes a legal conveyance in fee-simple of a copyhold tenement to the tenant, the tenement is said to be enfranchised, that is, converted into freehold.

Copyholders were till very lately incapable of serving on juries, or voting at county elections of members of parliament; but the former disability was removed by 6 Geo. IV. c. 50, s. 1, and the latter by the 2 & 3 Wm. IV. c. 45, s. 19. As to the qualification for killing game under 22 & 23 Car. II. c. 25, s. 3, there seems to be no distinction between freeholders and copyholders.

There are no lands of a copyhold tenure in Ireland.

The statute of wills, 1 Vict. c. 26, which has been before alluded to, contains also the following provisions as to the testamentary disposition of copyholds, which require notice here. The 4th section provides that where any real estate of the nature of customary freehold, or tenant right, or customary or copyhold, might by the custom of the manor of which the same is holden, have been surrendered to the use of a will, and the testator shall not have surrendered the same, no person claiming to be entitled under his will shall be entitled to be admitted, except upon payment of all such stamp duties, fees, and sums of money as would have been due in respect of the surrender of such estate, or the presentment, registering, and enrolment of such surrender to the use of his will. And also, that where the testator, being entitled to admission to any real estate, and upon such admission to surrender the same to the use of his will, shall not have been admitted thereto, no person claiming to be entitled to such real estate in consequence of such will shall be entitled to admission, except on payment of all such stamp duties, fees, fine, and sums of money as would have been due in respect of the admittance of the testator to such real estate, the surrender to the use of his will, the presentment, registering, or enrolment of such surrender; all such stamp-duties, fees, fine, or sums of money to be paid in addition to the stamp duties, fees, fine, or sums of money due on the admittance of the person so claiming to be entitled to such real estate.

By the 5th section, when any real estate of the nature of customary freehold, or tenant right, or customary, or copyhold, is disposed of by will, the lord of the manor, or reputed manor, of which such real estate is holden, or his steward, or the deputy of such steward, is to cause the will by which such disposition is made, or an extract thereof, to be entered on the Court Rolls; and when any trusts are declared by the will, it is not to be necessary to enter the declaration of such trusts, but it is to be sufficient to state in the entry on the Court Rolls that such real estate is subject to the trusts declared by the will; and when such real estate could not have been disposed of by will, except by virtue of the act, the same fine, heriot dues, duties, and services are to be paid and rendered by the devisee as would have been due from the customary heir in case of the descent of such real estate. And the lord is, as against the devisee, to have the same remedy for recovering and enforcing such fine, heriot dues, duties, and services as he is entitled to against the customary heir in case of a descent.

By the 6th section, if no disposition by will be made of any estate *pur auter vie* of a freehold nature, the same is to be chargeable in the hands of the heir, if it come to him by reason of special occupancy, as assets by descent, as in the case of freehold land in fee simple; and in case there be no special occupant of any estate *pur auter vie*, whether freehold or customary freehold, tenant right, customary or copyhold, or of any other tenure, and whether a corporeal or incorporeal hereditament, it is to go to the executor or administrator of the party that had the estate by virtue of the grant; and if the estate come to the executor or administrator, either by reason of a special occupancy or by virtue of the act, it is to be assets in his hands, and to go and be applied and distributed in the same manner as the personal estate of the testator or intestate. By the 26th section a general devise of the testator's lands is to include copyholds, unless a contrary intention appear by the will; which is an alteration of the old rule whereby copyholds did not pass under a general devise of "lands, tenements, and hereditaments," or other general words descriptive of real estate, unless the copyholds had been surrendered to the use of the will, or the testator had no freehold lands upon which it could operate. And besides the above-mentioned changes relating peculiarly to copyholds, all the other enactments of the act, including that which prescribes the formalities to be observed in making a will, are applicable to estates of copyhold or customary tenure.

By the 11th section of the 1 & 2 Vict. c. 110, copyholds are made subject to execution by judgment creditors in the same manner as freeholds.

Still greater changes in the nature of estates of copyhold and customary tenure are gradually taking place under the provisions of the stats. 4 & 5 Vict. c. 35; 6 & 7 Vict. c. 23; 7 & 8 Vict. c. 55; 15 & 16 Vict. c. 51: and 21 & 22 Vict. c. 94.

The principal objects of these Acts are, 1. The commutation of certain manorial rights in respect of lands of copyhold and customary tenure; 2. The facilitating the enfranchisement of such lands; and 3. The improvement of such tenure. The first of these Acts provided a cumbrous machinery for general commutations which was not found very effective, and it merely enabled commutations and enfranchisements to be made, where all parties were agreed, but without empowering either party, whether lord or tenant, to compel the other to enfranchise or commute. Under its enactments, however, a good many enfranchisements took place in the case of manors of which ecclesiastical bodies were the lords, under the direction of the ecclesiastical commissioners. The Act 15 & 16 Vict. c. 51 (1852), first introduced the important principle of enabling one party, whether lord or tenant, to compel the concurrence of the other in enfranchisement, and this Act has been found very efficacious. Its first section enacts, that "at any time after the next admittance to any lands which shall take place on or after the first day of July, 1853, in consequence of any surrender, bargain and sale, or assurance thereof (except upon or under a mortgage in cases where the mortgagee is not in possession), or in consequence of any descent, gift, or demise, and whether such surrender, bargain and sale, or assurance, shall have been made, passed, or executed, or such descent shall happen, or such gift or demise shall take effect before or after that day, it shall be lawful for the tenant so admitted, or for the lord, to require and compel enfranchisement in manner hereinafter mentioned of the lands to which there shall have been such admittance as aforesaid." The mode of effecting enfranchisement directed by this Act has been since altered by 21 & 22 Vict. c. 94 (1858), of which the eighth section enacts, that "when any lord or tenant shall, under the provisions of the Copyhold Act, 1852, or of this Act, require the enfranchisement of any land held of a manor, he shall give notice in writing (the lord or his steward to the tenant, or the tenant to the lord or his steward) of his desire that such land shall be enfranchised, and the consideration to be paid to the lord for such enfranchisement, and also the sum to be paid to the lord in respect of a heriot due for a customary freehold, shall, unless the parties agree about the same, be ascertained under the directions of the copyhold commissioners, and upon a valuation made in manner following: (that is to say), when the manorial rights to be compensated shall consist only of heriots, rents, and licences, at fixed rates, to demise or fell timber, or any of these, or when the land to be enfranchised shall not be rated to the poors' rate at a greater amount than the net annual value of 20*l.*, then the valuation shall be made by a valuer to be nominated by the justices at a petty session holden for the division or place in which the manor or the chief part thereof is situate: provided that no justice, being lord, either in whole or in part, of such manor, shall take any part in nominating such valuer; subject, however, to these provisoes: first, that if the parties agree to recommend to the commissioners any person to be the valuer, such person shall be nominated by the commissioners; and second, that either party may, upon paying the charges of his own valuer, have the valuation made as next hereinafter provided. But when the manorial rights to be compensated do not consist only of rents and heriots and such licences as aforesaid, or when the land to be enfranchised is rated to the poors'-rate at a greater amount than the not annual value of 20*l.*, or where the valuation to be made is of the sum to be paid to the lord in respect of a heriot due for a customary freehold, then the valuation shall, unless the parties agree to refer it to one valuer, be made by two valuers, one to be appointed by the lord, and the other by the tenant; and such two valuers, before they proceed, shall appoint an umpire, to whom any points in dispute between them shall be referred; and in case the valuer or valuers, or umpire, as the case may be, shall not make a decision and deliver the particulars thereof in writing to the lord or steward and to the tenant, and to the copyhold commissioners, within forty-two days after the appointment of such valuers, or reference of the matter to the umpire, as the case may be, then the commissioners shall fix the consideration to be paid or rendered to the lord; and in any case when, after notice to the lord or steward, or to the tenant so to do, either party shall neglect or refuse, for twenty-eight days, to appoint his valuer, the commissioners shall appoint a valuer for him as soon as may be after the expiration of such twenty-eight days; and in any case where any valuers shall, for the space of fourteen days after the appointment, be unable to agree in the appointment of an umpire, the commissioners shall appoint an umpire." This last-mentioned Act also enables lord or tenant to compel enfranchisement of a copyhold to which the last admittance shall have taken place before the 1st of July, 1853.

The following table, which is taken from the 'Seventeenth Report of the Copyhold Commissioners,' dated December 31, 1858, will show what has been effected under the operation of the enfranchisement Acts. The table distinguishes the manner in which enfranchisement has taken place into clerical, collegiate and lay, and shows the number of distinct operations, whether of enfranchisement or commutation, which have taken place in each during a period of seventeen years from the first commencement of the system:—

Years.	Clerical.	Collegiate.	Lay.	Total.
1841	1	—	—	1
1842	9	—	3	12
1843	15	1	13	29
1844	24	—	15	39
1845	44	—	12	56
1846	49	—	7	56
1847	38	1	13	52
1848	16	1	8	25
1849	19	1	10	30
1850	27	1	9	37
1851	31	2	31	64
1852	31	—	13	44
1853	36	6	16	58
1854	59	11	61	131
1855	42	32	146	220
1856	46	23	162	231
1857	52	21	230	303
1858	32	13	159	204

The rapid increase of enfranchisements under the operation of the compulsory clauses is observable, and ultimately it may be anticipated that copyhold tenure will cease to exist.

COPYING-MACHINES. The great value of a convenient and certain means of copying any piece of writing with perfect accuracy, and with less labour than is involved in the process of transcribing, has led to numerous inventions which may be classed under the general name of copying-machines, some of which are extensively used in mercantile establishments for producing duplicates of letters, invoices, and other MS. papers.

The most simple and obvious mode of effecting this object is by transferring, by means of a rolling or screw-press, a portion of the ink with which a letter is written to the surface of a sheet of blank paper, prepared to receive it by damping. The transfer thus obtained is of course the reverse of the original letter, and, unless it be taken on paper so thin and transparent that it may be read through it, must be read backwards. Watt's copying-press was a contrivance for obtaining transfers of this kind upon thin unsised paper, wetted, and then placed between two woollen cloths, which absorbed all unnecessary moisture. Elegant screw-presses of iron are manufactured for this purpose, of various designs; some having the power applied solely by means of a screw, turned by a transverse bar or lever, or by a cross or wheel-shaped handle; while others have also a contrivance for increasing the pressure beyond what can be conveniently applied by the simple turning of the screw. One of the best and simplest copying-presses is that invented by Mr. Ritchie, of Edinburgh, in which the platten is depressed by a screw, turned by a short transverse handle, until a moderate pressure is given; after which, by the movement of a second lever-handle acting upon an excentric cam, which bears upon a piece of steel attached to the head of the screw, the screw and platten are further depressed through a very small space, but with immense force. Barlow describes a very simple and compact copying-machine invented by the elder Brunel, in which the pressure is given by means of levers. In some cases, letters intended for transferring by the copying-press are written with an ink made for the purpose; or, when common ink is used, it may be thickened by adding a little sugar to it. In some cases the transfers are taken from the pages of a MS. book prepared for the purpose, a sheet of dry oiled paper being placed over the damp sheet to prevent the transmission of the moisture. It is almost needless to observe that transfers may be taken from several written sheets at one operation of the press.

Hebert gives the following description of a simple, and, he says, effectual copying-machine: "Take a roller of beech, or any hard wood, about 18 inches long and 1 inch in diameter, and having cut a longitudinal slit therein nearly the whole length, insert in it and fasten very neatly with glue a slip of strong cloth, about 14 inches wide and 18 inches long; the remaining part of the roller will serve as a handle, and may be cut with several faces to obtain a firmer hold. To use this copying-press, lay the sheet of paper on which the letter is written upon the strip of cloth; on that place the thin copying-paper, and upon these lay a thick baize or horse-hair pad; then roll the whole round the roller, and grasping that part where the cloth is with the left-hand, turn the roller round with the right, gradually increasing the grasp with the left; the pressure becomes very great, and quite sufficient to transfer the letter to the copying-paper."

Holland, in Lardner's 'Cabinet Cyclopædia,' mentions a plan suggested by Dr. Franklin, which, although he styles it ineligible in practice, is worth recording as conveying an idea which might be usefully applied. He proposed to write the original letter with a gummy ink, and then to strew it over with flour-emery, which would be retained by the ink, though it would not adhere to any other part of the surface of the paper. The writing was then to be laid, face downwards, upon a smooth pewter-plate, and subjected to the action of a powerful rolling-press, which, he conceived, would cause the emery to make an impression of the writing upon the surface of the metal, which might be charged with printing ink, and printed from like an engraved plate.

Mechanical contrivances for enabling a person to write with two pens or pencils at once, on different sheets of paper, on the principle of the PANTOGRAPH, have been tried as copying-machines; but they are too complicated for ordinary use. All such machines, and perhaps we might say even the copying-press, are far surpassed in convenience by the *manifold writer*, an apparatus patented in 1806, by Wedgwood. In this apparatus a sheet of paper blackened on both sides with printers' ink, and dried for five or six weeks between sheets of blotting-paper, or covered with some other black composition which will come off when pressed hard, but will not move with a slight degree of pressure or friction, is laid between two sheets of thin writing-paper, and the whole is placed upon a smooth copper or pewter-plate. The letter is then written firmly on the upper sheet of paper with an agate style or point, the pressure of which causes the blackened paper to produce two impressions of the writing, one, which is read through the paper, upon the under side of the sheet directly acted upon by the style, and the other upon the upper side of the lower sheet. More than two impressions of the writing may be obtained by using two or more sheets of blackened paper, interposed between several sheets of thin white paper. This apparatus is conveniently fitted up in a small portfolio, and occupies no more room than an ordinary writing-case.

In a machine registered by Messrs. Mordan, a stamping-press is combined with an ordinary copying-machine. When worked in the customary way, the platten rises with the screw, leaving a space beneath it for the copying process; but by a little adjustment the screw may be raised without the platten, leaving a die and counter-die in proper position for stamping any device on letters, envelopes, or paper.

In 1855 Mr. Terry patented a copying-machine to be combined with the cover of a book. The act of closing the book furnishes the means for copying documents placed between the leaves. Outside each cover is a metallic frame; one of these carries an inclined projecting piece at each end, while the other has two or three links hinged to each end. When the book is to be closed, the links are pressed over the inclined projecting pieces, and may be thus held compressed for any length of time. The pressure is sufficient to effect a transfer of ink as in a copying-press; but great rigidity in the frames is required.

COPYRIGHT, or, as it was formerly termed, copy, has been defined by Lord Mansfield, "to signify an incorporeal right to the sole printing and publishing of somewhat intellectual, communicated by letters." By this "somewhat intellectual" is to be understood something proceeding from the mind of the person by whom, or through whom, such a right is claimable. Yet, although mere republications of the compositions of others are no subject for copyright, it is by no means limited to such productions as contain new or original ideas. Thus translations both from ancient and modern languages, notes and additions to existing works, even compilations and abridgements, are similarly protected. As to these last however it is often a question for courts and juries to decide, whether the compiler or abridger really intended to present the original matter in a more useful or agreeable form, expended his own labour upon it, and so entitled himself to protection, or whether he only sought, under false pretexts, to defraud the author or his assigns of a portion of their lawful profits. This decision depends of necessity on the circumstances of each particular case. Further, a right of copy attaches to the authors of ideas expressed by other symbols as well as letters, to musical composers for example.

The origin of copyright must be sought in the general conviction which has always prevailed of its justice and expediency. "When a man," says Blackstone, "by the exertions of his rational powers has produced an original work, he seems to have clearly a right to dispose of that identical work as he pleases; and any attempt to vary the disposition he has made of it, appears to be an invasion of the right. Now the identity of a literary composition consists entirely in the sentiment and the language. The same conceptions, clothed in the same words, must necessarily be the same composition; and whatever method be taken of exhibiting that composition to the eye or ear of another, by recital, by writing, or by printing in any number of copies, or at any period of time, it is always the identical work of the author which is so exhibited, and no other man, it hath been thought, can have a right to exhibit it, especially for profit, without the author's consent." ('Comm.' Dr. Kerr's ed., vol. ii., p. 414.)

Accordingly it has been supposed that a common-law right of copy existed in England previously to any statute on the subject. As a legal proposition however this cannot be supported by the proper and direct proof of a fair judicial decision before the passing of the first statute relating to it in the reign of Queen Anne; inasmuch as it never appears to have been directly controverted up to that time. But, in the absence of positive authority, it may be fairly inferred, from the old charters of the Stationers' Company, and much more from their registers, whence it appears that some thousands of books, even as early as the times of Elizabeth, passed from one owner to another by descent, sale and conveyance; from acts and ordinances of parliament which necessarily imply a recognition of it by the nature of their provisions respecting printing; and from decrees of the Star-chamber, which, though not binding precedents, are evidence of the opinion of many learned men as to the then state of the law. It is further to be noted, that the non-existence of express decisions on the point is accounted for down to 1640 by the necessity of obtaining a licence prior to the printing of anything, so that authors had no occasion to apply to civil tribunals for protection, as none but themselves and those claiming under them were so licensed, and he who printed a book without this was subject to enormous penalties.

It has hardly been controverted in the various arguments that exist upon this common-law right of copy that literary compositions in their original state, and the incorporeal right of the publication of them, are the private and exclusive property of the author. The question made has been that this property was put an end to by publication; and yet without publication it is useless to the owner, because it is without profit, and property without the power of use or disposal is not property. In that state it is lost to society as a means of improvement, as well as to the author as a means of gain. Publication is therefore the necessary act and only means to render such a property useful to the public and profitable to the owner. If, says Lord Mansfield, the copy which belonged to the author before publication does not belong to him after, where is the common law to be found which says there is such a property before. All the metaphysical subtleties from the nature of the thing may be equally objected to the property before. It is equally detached from the manuscript or any physical existence whatsoever. There is in fact nothing in the act of publication to vary the nature of the right, so that that which is necessary to make a work useful and profitable should be taken as destructive at once of an author's confessed original property against his expressed will. It has accordingly been the almost unanimous opinion of the high authorities who were called on to decide the point, that by the common law of England authors were entitled to copyright, and as there was nothing in statute or custom to determine it, or distinguish this from other species of property, that such right was once perpetual. The arguments for the contrary opinion are collected in the judgment of Mr. Justice Yates in the case of Millan *v.* Taylor, 4th Burrow, p. 2354.

From the above premises arose the question, after the passing of the first statute respecting literary property in 1710, whether by certain of its provisions this perpetual copyright at common law was extinguished for the future. After some less important decisions in the negative on motion in the Court of Chancery and elsewhere, the question was solemnly argued before the Court of King's Bench, during the term, when Lord Mansfield presided, in 1769. The result was a decision in favour of the common-law right as unaltered by the statute, with the disapproval however of Mr. Justice Yates. Subsequently, in 1774, the same point was brought under the consideration of the House of Lords, and the decision of the court below reversed by a majority of six judges in eleven, as Lord Mansfield, who adhered to the opinion of the minority, declined to interfere; it being very unusual, from motives of delicacy, for a peer to support his own judgment on appeal to the House of Lords. It is somewhat remarkable, that although this could be hardly termed a decision, as the judges were in point of fact divided equally, it has since been held so important as a precedent and sustained in so many subsequent cases, that it must now be considered as settled law that perpetual copyright is put an end to by the statutes. And in a recent case, Jeffreys *v.* Boosey (4 Ho. of Lords ca. 815), the House of Lords has even decided that at common law no copyright exists.

The two universities were not slow to protect themselves from the consequences of this decree in the case of Donaldsons and Beckett, and obtained from Parliament, in 1775, the following year, an Act for enabling the two universities in England, the four universities in Scotland, and the several colleges of Eton, Westminster, and Winchester, to hold in perpetuity their copyright in books given or bequeathed to the said universities and colleges for the advancement of useful learning and other purposes of education. This protection, sanctioned by penalty and forfeiture, so long as such books are printed at the presses of the universities and colleges respectively, is still enjoyed, unaffected by the general statutes on the subject; and a similar protection is extended to the university of Dublin by 41 Geo. III. c. 107.

The chief provisions of the 8 Anne, c. 19, entitled 'An Act for the encouragement of learning, by vesting the copies of printed books in the authors or purchasers of such copies during the times therein mentioned,' as regards the effecting of that purpose, were, that the authors of books already printed, and those claiming under the author, should have the sole right and liberty of printing them for a term of 21 years and no longer; and that the authors of books to be printed, and their assigns, should have the same right for 14 years and no longer. And the last clause of the Statute directed that after the expiration of these 14 years the same right should return to the authors, if living, for another 14 years. The persons infringing these provisions were to be punished by forfeiture of the pirated book to the proprietor, and a penalty of one penny for each sheet, one-half to go to the crown and the other half to the informer, provided always the title to the copy of the book had been duly entered with the Stationers' Company.

The 41 Geo. III. c. 107, which extended the same law to Ireland, gave a further protection to authors and their assigns by action for damages and double costs, and raised the penalty per sheet to three pence, to be divided in the same way.

The 54 Geo. III. c. 156, enacted, that the author of any book, and his assigns, should have the sole liberty of printing and reprinting such book for the full term of 28 years from the day of publication, and, if the author should be living at the end of that period, for the residue of his natural life.

But the Act 5 & 6 Vict. c. 45 (Lord Mahon's Act), entitled 'An Act to amend the law of copyright,' and having for its preamble, "Whereas it is expedient to amend the law relating to copyright, and to afford greater encouragement to the production of literary works of lasting benefit to the world," is the Act which now regulates literary property. It repeals the 8 Anne, c. 19; 41 Geo. III. c. 107; 54 Geo. III. c. 156; and enacts that in every book published in the life-time of the author, after the passing of the Act (1st of July, 1842), the author and his assigns shall have copyright for the term of the author's life, and for seven years after his death, or if these seven years expire before the end of forty-two years from the time of publication, then for such period of forty-two years; while for books previously published, in which copyright still subsisted at the time of the passing of the Act, the copyright should be continued for the full term provided in the cases of books thereafter published, except in cases where the copyright should belong wholly or in part to a person other than the author, "who shall have acquired it for other consideration than that of natural love and affection." In these excepted cases however the author, or his personal representative, and the proprietor or proprietors of copyright may agree, before the expiration of the subsisting term of copyright, to accept the benefits of the Act: and on a minute of such agreement being entered in a book of registry directed to be kept at Stationers' Hall, the copyright will be continued, as in other cases, for the author's life and seven years after his death, or for forty-two years from the time of publication, and will be the property of the person or persons specified in the minute. The copyright of a book published after the author's death is to endure for forty-two years from the time of publication, and to belong to the proprietor of the manuscript from which it is first published, and his assigns. With regard to encyclopædias, reviews, magazines, periodical works, or works published in a series of books or parts, or any book in which the publisher or projector shall have employed persons to write, on the terms that the copyright shall belong to himself, the copyright shall be in the publisher or projector, after he has paid for it, in the same manner and for the same term as is given to authors of books, except only in the case of essays, articles, or portions forming part of, and first published in, reviews, magazines, or other periodical works of a like nature, the right of publishing which separately shall revert to the authors at the end of twenty-eight years after publication, for the remainder of the term given by this Act; and during these twenty-eight years the publisher or projector shall not have the right to publish any such essay, article, or portion separately, without the consent of the author or his assigns.

The Act provides, at the same time, against the suppression of books of importance to the public, by empowering the judicial committee of the Privy Council, on complaint made to them that the proprietor of the copyright in any book after the death of its author, refuses to republish or allow the republication of the same, to license the complainant to publish the book, in such manner and subject to such conditions as the Privy Council may think fit.

The remedies provided by this Act for infringement of copyright are, an action for damages (in which the defendant is required, on pleading, to give notice to the plaintiff of the objections to the plaintiff's title on which he means to rely), and a power given to the officers of customs and excise to seize and destroy all foreign reprints of books in which copyright exists, with a penalty on the importer (if he be not the proprietor of the copyright) of 10*l.*, and double the value of every copy of any book imported, on conviction before two justices of the peace; 5*l.* of the penalty to go to the officer of customs or excise who shall procure the conviction, and the remainder to the proprietor of the copyright.

The Act provides that a book of registry be kept at Stationers' Hall, where entries may be made of proprietorships of copyright, assignments thereof, licences of the judicial committee, and agreements as to copyrights subsisting at the time of the passing of the Act, on payment in each case of a fee of 5*s.* The entry of proprietorship of copyright in this book does not affect copyright; but no action can be brought for infringement of copyright, nor any other legal proceedings taken, unless the proprietorship of copyright has been entered.

The entry of an assignment in the registry book is to all intents and purposes an effectual assignment. Certified and stamped copies of entries in the registry book, are to be evidence in all courts of justice, and are to be taken as *primâ facie* proof of copyright. The making of a false entry in the registry book, or the production in evidence of any paper falsely purporting to be the copy of an entry therein, is made a misdemeanor. Persons thinking themselves aggrieved by any entry in the registry book, may apply to a court of law in term time, or a judge in vacation, for an order to vary or expunge such entry; and such court or judge may make an order for varying, expunging, or confirming such entry, with or without costs.

With respect to dramatic literary property and the 3 Will. IV. c. 15, which gave dramatic authors certain privileges and remedies for their infringement, the 5 & 6 Vict. c. 45, has extended the term of the sole liberty of representing dramatic pieces to the period provided by that Act for the copyright of books, and gives the same protection to the authors of musical pieces and their assigns. The remedies provided by the 3 Will. IV. c. 15, in the case of dramatic pieces are confirmed by the 5 & 6 Vict. c. 45, and extended to musical pieces. The 5 & 6 Vict. c. 45, also enacts that no assignment of the copyright of any book consisting of a dramatic piece or musical composition shall convey the right of representing or performing such dramatic piece or musical composition, unless an entry, expressing the intention that such right shall pass by the assignment, be made in the registry book at Stationers' Hall.

The protection given to authors by the Statute of Copyright is coupled with the condition of presenting five copies of every book to certain public libraries. A copy of every work, and of every second or subsequent edition which contains any additions or alterations, bound, sewed, or stitched together, and on the best paper on which the same shall be printed, is to be delivered at the British Museum within one month after its first publication, if it is published within the bills of mortality, or within three months if published in any other part of the United Kingdom, or within twelve months if published in any other part of the British dominions; and a copy of every work, or second or subsequent edition, containing additions and alterations, on the paper of which the largest number of copies shall be printed for sale, in the like condition as the copies prepared for sale by the publisher, is to be delivered, if demanded, within twelve months after publication, within one month after demand made, at Stationers' Hall, for the Bodleian Library at Oxford, the Public Library at Cambridge, the Library of the Faculty of Advocates at Edinburgh, and the Library of Trinity College, Dublin, under penalty of forfeiting the value of the copy of each book or edition not delivered, and a sum not exceeding 5*l.*, to be recovered by the Librarian, or other officer properly authorised, of the library to which the book should have been delivered, on conviction before two justices of the peace for the county or place where the publisher resides, or by action of debt in any Court of Record in the United Kingdom. Formerly, under the 54 Geo. III. c. 156, an author was obliged to give eleven copies of his work to public libraries.

The strict powers given by the 5 & 6 Vict. c. 45, have been vigorously exercised by the Custom-house authorities, and found very effectual to prevent the importation into this country of the French, Belgian, German, and American reprints of popular English works; but English authors still suffer by the circulation of these reprints abroad; and a practice so destructive of the fair profits of mental labour can only be effectually redressed by prevailing on foreign countries to extend the benefits of their own laws against literary piracy to aliens as well as native authors. Two Statutes have been passed in the present reign to enable her Majesty to extend to foreigners the benefits of our laws of copyright. The first of these, 1 & 2 Vict. c. 59, was repealed by 7 Vict. c. 12, the Statute which is now in force, and which was substituted in consequence of the alterations in our law of copyright. This Act, entitled "An Act to amend the law relating to International Copyright," empowers her Majesty by order in council to enable authors of works first published in foreign countries to have copyright in the British dominions for books, prints, articles of sculpture, and the sole liberty of representing dramatic and musical pieces, for periods not exceeding those allowed by the various copyright Acts for the respective classes of works when first published in this country, on conditions of registration and delivering of one copy at Stationers' Hall; but no such order in council is to have any effect unless it is stated therein, as ground for issuing the same, that reciprocal protection for British authors has been secured in the foreign country to which the order in council refers. Under this Act a convention for the mutual protection of copyrights has been entered into with France, and its stipulations have been confirmed by the Act 15 & 16 Vict. c. 12. Similar agreements have likewise been entered into with the free town of Hamburg (1853), with Belgium (1854), and with Prussia (1855).

There are certain works exempted from the benefit of the law of copyright from the nature of their contents: such are, all publications injurious to public morality, inimical to Christianity, or stimulating, either as libellous or seditious, to a breach of the peace. This must however be understood of their general tenor, and not of isolated passages. As far as a rule on the subject can be laid down, it is, that any work containing matter for which a public indictment or private prosecution could be sustained is not protected by the law, but may be pirated by other parties at pleasure, who, if sued for penalties under the Act, are allowed to give in evidence the nature of the composition which they have published, in order to defeat the action. This is a remarkable exception to the general rule of law, that none shall take advantage of his own wrong; and its operation is quite as remarkable, the effect of the rule having often been to disseminate more widely that which the law has declared not to merit protection.

Besides the special copyrights of the universities secured to them, as before mentioned, by Statute, there still exist certain prerogative copyrights attaching to the owners in perpetuity. Of these the chief belong to the queen, which were more numerous and considerable formerly than at present. The right to print the authorised translation of the Bible without note or comment belongs to the crown, and of this right the Universities of Oxford and Cambridge and the queen's printers are now patentees. Other persons may however print this translation, provided it be accompanied with *bonâ fide* notes (2 Burr. 661). Many other copyrights formerly vested in the crown are now quite obsolete, such as those of almanacs, law-books, and Latin grammars. The crown has a prerogative copyright in the liturgy and other services of the Church, in proclamations, orders in council, and other state papers, and in the statutes. It has been decided that the University of Cambridge shares by letters patent in the crown's prerogative of printing Acts of Parliament. The House of Lords also exercises an exclusive privilege, somewhat fallen into disuse, of publishing its own proceedings as the supreme court of judicature.

The usual modes of legal proceeding to prevent or punish the infringement of copyright, or, as it is more usually termed, piracy, are by action for damages, or for the penalties given by the statute; or more commonly still, by obtaining an injunction in equity to prohibit the unlawful publication, which affords immediate and summary redress. This is always granted where the legal title of the plaintiff to the work is made out, and the identity of the pirated publication with his own shown to the satisfaction of the court. The proof even of an equitable title has been held sufficient to qualify him for this remedy. (Mawman *v.* Tegg, 2 Russ. 385.) Neither will the court be restrained from granting the injunction, by proof that the matter pirated forms only a part of the publication complained of, and that what is original will be rendered useless to the defendant and the public by prohibiting its sale. But as this mode of proceeding presses very severely upon defendants, and often inflicts irreparable injury, the court, where any doubt attaches, will either refuse the injunction altogether, or grant it only on condition of the plaintiff's bringing an action immediately, to have the merits of the case decided by a jury with the smallest possible delay.

A notice of the law of copyright would be incomplete which did not advert to some other compositions which receive from statute a protection analogous to that of literature. Such are engravings, etchings, and prints, maps and charts, and sculpture of all kinds. These resemble written works as regards the incorporeal right in them accruing to the author by the exertion of his mental powers in their production, but differ, as they also require a good deal of his manual skill and labour, and are therefore his property upon the same general principles as any other manufacture. Such productions therefore are even more plainly entitled to the protection of the law than books.

The chief statutes affecting the copyright in works of design, engraving, and etching, are the 8 George II. c. 13, which vest it in the inventor, designer, and proprietor, for fourteen years from the first publication, and enforces this provision against any person pirating the same by forfeiture of the plate and prints, and a fine of five shillings for each print, to be recovered by action within three months of the discovery of the offence. The 7 George III. c. 38, extends the term of copyright to twenty-eight years; and, in addition to the subjects of the former statute, includes maps, charts, and plans, under the same conditions. It also extends the time of bringing an action for the penalties to six months. The 17 George III. c. 57, gives the owner of the copyright a further remedy of action for damages and double costs within the same limits of time. The 6 & 7 Will. IV. extends the provisions of these Acts to Ireland. The 15 & 16 Vict. c. 12, brings lithographs or impressions taken by other means of indefinite multiplication within the provisions of the preceding Acts.

With regard to models, casts, and other sculptures, the 38 George III. c. 71 vests the right and property in these for fourteen years in the proprietor, and gives him a special action on the case against the offender, if brought within six months. These provisions were rendered more effectual by 54 George III. c. 56, by which double costs were given, and an additional term of fourteen years superadded in case the maker should be living at the end of the first term.

As to sculpture certainly, but more doubtfully as to prints, for there have been conflicting decisions on the point, the work must bear upon it the name of the maker and the date of publication to entitle it to the protection of the law.

By the Designs Act, 1850 (13 & 14 Vict. c. 104), provision is made for the registration of productions of sculpture, casts, models, and the like.

With regard to designs for manufactured articles, the 27 Geo. III. c. 38, continued by 29 Geo. III. c. 19, and confirmed and made perpetual by 34 Geo. III. c. 23, gave the sole right of using a new pattern in the printing of linens, cottons, calicoes, and muslins for three months; and the 2 Vict. c. 13 extended this privilege to designs for printing other woven fabrics besides calicoes. The 2 Vict. c. 17 regulated copyright of designs in all articles except lace, and the articles to which the above-mentioned Acts apply. But all these statutes were repealed by the 5 & 6 Vict. c. 100 (amended by 6 & 7 Vict. c. 65), which considerably extended the periods of copyright in designs.

This Act distributes articles to which designs may be applied into twelve classes :—

1. Articles of manufacture composed wholly or chiefly of any metal or mixed metals.
2. Articles of manufacture composed wholly or chiefly of wood.
3. Articles of manufacture composed wholly or chiefly of glass.
4. Articles of manufacture composed wholly or chiefly of earthenware.

5. Paper-hangings.
6. Carpets.
7. Shawls, where the design is applied solely by printing, or by any other process by which colours are or may hereafter be produced upon tissue or textile fabrics.
8. Shawls not comprised in class 7.
9. Yarn, thread, or warp, the design being applied by printing, or by any other process by which colours are or may hereafter be produced.
10. Woven fabrics, composed of linen, cotton, wool, silk, or hair, or of any two or more of such materials, if the design be applied by printing, or by any other process by which colours are or may hereafter be produced upon tissue or textile fabrics; except the articles included in class 11.
11. Woven fabrics composed of linen, cotton, wool, silk, or hair, or of any two or more of such materials, if the design be applied by printing, or by any other process by which colours are or may hereafter be produced upon tissue or textile fabrics, such woven fabrics being or coming within the description technically called furnitures, and the repeat of the design whereof shall be more than twelve inches by eight inches.
12. Woven fabrics not comprised in any preceding class.
13. Lace, and any article of manufacture or substance not comprised in any preceding class.

The Act gives to the proprietor of a design not previously published the sole right of applying it to ornamenting articles of the first, second, third, fourth, fifth, sixth, eighth, and eleventh classes, for three years; to articles of the seventh, ninth, and tenth, for nine months; and to articles of the twelfth and thirteenth classes for twelve months; whether such design be applicable for the pattern, or for the shape and configuration, or for the ornament of the articles, or for any two or more such purposes, and by whatever means the design may be applicable, whether by printing, or by painting, or by embroidery, or by weaving, or by sewing, or by modelling, or by casting, or by embossing, or by engraving, or by staining, or by any other means whatsoever, manual, mechanical, or chemical, separate, or combined. The benefits of copyright of designs are made to depend on registration before publication. Piracy is punished by a penalty of not less than 5*l.* nor more than 30*l.*, to be paid to the proprietor of the design, and to be recovered by an action of debt or for damages, or by summary proceeding before two justices.

The law of patents in many respects resembles that of copyright. [PATENT.]

The Act "for preventing the publication of lectures without consent" (5 & 6 Wm. IV. c. 65) gives to authors of lectures the sole right and liberty of printing and publishing the same, and imposes a penalty on other persons, including printers and publishers of newspapers, who shall print, or publish, or sell them without the author's leave. The Act does not extend to lectures of the delivering of which notice in writing shall not have been given to two justices, living within five miles of the place, two days at least before their delivery, or to any lecture delivered in any university, or public school or college, or any public foundation, or by individuals in virtue of any gift, endowment, or foundation. The Act does not extend to sermons.

COR CA'ROLI, a name given by Halley to the star of the third (or 2½) magnitude in Canes Venatici, in memory of Charles I. It is situated on the neck of the lower dog, and, when figured, has a heart surmounted by a crown. The name is not much in use among astronomers.

COR LEONIS. [REGULUS.]

CORAL FISHERY. Coral (for a zoological account of which see POLYPIARIA, in NAT. HIST. DIV., and other articles there referred to) is a marine production so nearly resembling some plants in appearance, that it is has been supposed to belong to the vegetable kingdom, although it is now known to consist of the cells or habitations of minute animals, so built upon one another as to produce a branched tree-like structure, often very beautiful in form and colour, and exceedingly hard. Being much sought after, especially by the natives of India, for ornamental purposes, coral, in those places in which it is found of good quality, forms an important article of commerce. Coral was known to the ancients under the name *corallium*, or *κοράλλιον*, and as is shown by Pliny's description, they erroneously supposed it to be soft while in the sea, and to harden by contact with the air, or by touching with the hand. (Holland's translation of Pliny's 'Natural History,' book xxxii. vol. ii. p. 429.) It is found abundantly in various parts of the Mediterranean Sea, in the Red Sea, the Persian Gulf, and several other places, in which the coral fishery forms the laborious and dangerous occupation of a large class of men. A full account of the coral fishery in the Straits of Messina is given in the fourth volume of Spallanzani's 'Travels in the two Sicilies' (English translation, 1798, pp. 306–329), from which it appears that the rocks which yield coral are situated in the middle of the strait, and that the parts from which it is taken vary from about 350 to 650 feet below the surface of the water. The coral here grows to about the height or length of twelve inches, and requires eight or ten years to come to perfection. The fishing-ground is therefore divided into several portions, from each of which the coral is removed only once in ten years. When taken at shorter intervals the coral is of smaller size, but it does not appear that it materially increases in length if left for a longer period, although its stems become somewhat thicker. The free access of the rays of the sun through the water appears to be essential to the perfection of the coral, which, we are told, always grows nearly perpendicular to the surface of the rock to which it is attached, whatever the position of the rock itself may be. It is of various colours, from black or brilliant red to a dull white, and varies exceedingly in value, some selling for as much as eight or ten guineas per ounce, while other sorts are not worth a shilling per pound. The mode of conducting the fishery in various places is much the same. In that described by Spallanzani, the instrument used consists of two heavy beams of wood, secured together at right angles in the form of a cross, and loaded at their intersection with stones or other weights sufficient to sink them. A quantity of loosely twisted hemp, intermixed with coarse netting, is attached to the under side of the beams, at the ends of the cross, to the middle of which is secured one end of a strong rope by which the apparatus is let down from a boat, and guided to the spots where the coral is supposed to be most abundant. The branching form of the coral causes it to become entangled in the hemp and network attached to the cross, by which means it is broken off from the rock, and drawn up with the apparatus to the surface of the water. Owing to the great depth at which the fishery is carried on, the submarine movement and drawing up of the cross is a laborious operation, sometimes requiring the united efforts of half a dozen boats; and the men employed are exposed to considerable danger in case of the rope breaking. Other machines are used by the coral-fishers of Marseille, in the fishing-grounds of what is called the "bastion of France;" one of these, called in the Provençal language the *salabre*, is intended for situations in which the bottom of the sea is rough and uneven. With a few trifling variations, however, all the instruments of which we find any account, consist of weighted beams supplied with network, or some substitute for it, to entangle and break off the coral. In some cases a diver descends to guide the ends of the cross into caverns which they would not otherwise enter; and an iron hoop fixed to the beam is occasionally used to break coral from the roof or sides of caverns, a net being attached beneath it to secure what is thus broken off.

Some of the ornamental articles made of coral are very costly. Besides necklaces, and the trinkets called childrens' corals, the material is wrought into bracelets, ear-ring drops, cameos, carvings, and statuettes. The material is very hard, and requires sharp instruments to work it.

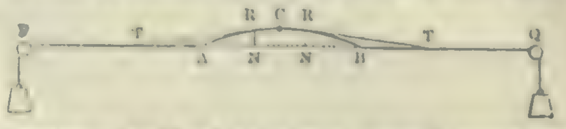
CORANTO. [COURANTE.]

CORBEL, a term used chiefly in Gothic architecture to signify a projecting piece of stone, wood, or iron, placed so as to support a weight of materials. Corbels are sometimes in the form of the modillion or mutule employed in entablatures, and also like the console of a window. Small semicircular towers projecting at the angles on perpendicular surfaces of large towers or other edifices are supported on a series of plain or moulded corbel stones. The weather-mouldings of semicircular windows are often supported in the same manner. The machicolations of towers are almost always supported on corbel stones, as may be observed in the old gates of Southampton, Canterbury, and York. This projecting of one stone beyond another is technically called "corbelling out." This is done in brickwork as well as in masonry. In the interior of some churches the construction of the roof appears to be supported on corbels, the ends of which are often carved, and represent an angel holding a shield. In Norman and Early English architecture the cornice is supported by a row of corbel stones, known as the *corbel-table*, the ends of which are also carved. In old English castles the main beams of the floors were frequently carried on large corbel stones, as at Porchester Castle. The term bracket is sometimes used for a corbel. Bracket, however, is better applied as synonymous with cantilever. Small wooden brackets often differ from corbels and cantilevers in being merely nailed to a perpendicular piece of wood and not having a bearing on a wall, as is always the case with corbels and cantilevers.

CÒRD, frequently spelt chord, means an elastic string fixed at the two extremities and stretched with force sufficient to enable it to yield a musical note. [ACOUSTICS.] The close analogy which exists between a string and a column of air in a state of vibration would require more space to elucidate properly than this subject will allow us to give: we shall therefore assume some results of mathematical reasoning, point out the probability of those results, and consider the theory of the vibrating cord independently.

Firstly, we suppose our cord to be of uniform thickness and density so that any given length is precisely of the same quality, from what part soever of the string it may be cut. The want of this condition being practically fulfilled is sometimes sensibly felt in violin and violoncello strings, which are then called *false*. A player whose intonation is perfect upon a perfect string, has to learn a new instrument when he attempts to play with a false string; to say nothing of the harmonics which must be heard more or less becoming uncertain, if not discordant.

Let us first suppose a string of indefinite length, and not so acted upon by gravity as to bend downwards, stretched at the two ends by equal weights. The string is a cylinder of uniform diameter and density. Let us next suppose that a part of the string is placed on a mould which catches two points and holds them fast, and stretches the intermediate part into a curve which differs very little from a straight line. Let the mould be suddenly removed, and let us further suppose that, in removing it, we are able to communicate any velocities we please to the different points of the stretched part. We have then, at the moment of starting, a system represented in the following diagram, where A B (dotted) represents the part in question before the mould was applied, and it is A C B the instant the mould is taken away, all the points between A and B being in a state of motion upwards or downwards.



The string will not remain an instant in its present state: the first presumption is that the moment the points A and B are set free a disturbance will take place in the parts of the string both between P and A, and between Q and B, the disturbance travelling from A towards P as well as from B towards Q. The first point in which we are interested is this: with what velocity will the disturbance be propagated? and the answer is, that the disturbance travels throughout the string with the same velocity, depending upon its material and the weight with which it is stretched, according to the following law: Let each of the equal weights P and Q be as heavy as *c* feet of the string; then the velocity of communication is so many feet per second as a bullet would acquire, if it were allowed to fall *in vacuo* down a perpendicular of *c* feet, or $\sqrt{2gc}$, where g is the velocity which gravity communicates in one second, or $32\frac{1}{6}$ feet. For instance, let the string be iron wire, every cubic foot of which weighs 7200 ounces avoirdupois. Let the diameter be one-twentieth of an inch, and let the weights P and Q be each 20 pounds or 320 ounces. Then the weight of x feet of the string is ($\frac{1}{20}$ of an inch being $\frac{1}{240}$ of a foot)

$$3{\cdot}14159 \times (\tfrac{1}{480})^2 \times x \times 7200 \text{ ounces}$$

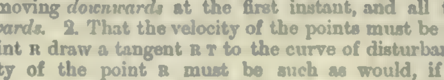
which made equal to 320 gives $x = 3259{\cdot}5$ feet and

$$\sqrt{2 \times 32\tfrac{1}{6} \times 3259{\cdot}5} = 457{\cdot}93 = 458 \text{ nearly},$$

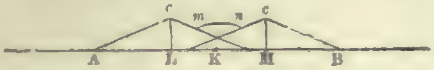
or 458 feet per second is the rate at which the disturbance is communicated.

We now ask what is the nature of the disturbance communicated. It suggests itself as possible, that there may be some species of disturbances which travel only in one direction: for instance, that we might so proportion the velocities of the disturbed points to their positions, that A P should remain undisturbed, that the points from A towards the right should drop one after another into their places, while those from B to Q should be successively disturbed. The answer, again derived from mathematics, is, that such disturbance is possible, and that the conditions under which it will take place are: 1. That C being the highest of the disturbed points, all the points from A to C must be moving *downwards* at the first instant, and all those from B to Q *upwards*. 2. That the velocity of the points must be as follows: At any point R draw a tangent R T to the curve of disturbance. Then the velocity of the point R must be such as would, if continued uniformly, carry the point R from R to N or from N to R in the same time as the whole disturbance is propagated from T to N. These conditions being fulfilled, we may represent the successive states of the string by cutting out a piece of paper of the form A C B, and carrying it along the string P Q at the uniform rate per second which we have found for the propagation of the disturbance. If the directions of the velocities be all reversed, then the disturbance travels from B towards P. Let us call such disturbances *simple;* and with respect to the direction in which they travel, *direct* or *retrograde*. We further learn from mathematical analysis, that any disturbances whatsoever, taking place upon the same points at the same instant, produce a compound disturbance of which the values of R N and the velocities at the point R in the compound disturbances are the algebraical sums of the values of R N, &c., in the component disturbances. And moreover, that any disturbance whatsoever, be the law of its form and velocities what it may, can be compounded of two simple disturbances, one direct and one retrograde. So that the moment the mould is removed, the two simple disturbances will begin to travel in different ways. As long as they have not completely separated, there will be points remaining under the effects of both: but when they have had time to separate completely, we should, were the rapidity of transmission not too great, see the direct disturbance travelling by itself in one direction and the retrograde in the other.

To illustrate this, suppose we wish to ascertain the effect of the disturbance A C B, as drawn, the velocities throughout being nothing at all at the instant the mould is withdrawn. The two simple disturbances which would produce this are two of the form A C B, such that at any point R the velocity would bring the point through R N while the disturbance is communicated through A N. If we suppose

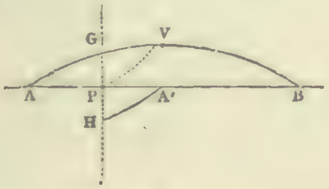


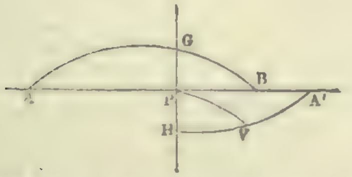
a direct and retrograde disturbance of such a kind, there will be at the first moment no velocity at any point of A C B, since those of the direct and retrograde disturbance compensate each other throughout. But



let a time elapse during which the direct and retrograde disturbances travel to M and L. Then the form of the string at that moment will be A c m n c B, where the part m n arises from the composition of the two parts of the disturbances which yet remain acting on the same points.

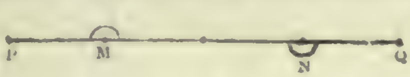
We may thus trace the effect of disturbance upon an indefinitely extended string; but such a string would produce no musical sound, for which it is necessary that there should be a continued reiteration of the same action upon the air repeated at equal intervals. Now supposing a finite string, stretched at the ends, we must ask what takes place when the disturbance comes to the end of the string. And from mathematical analysis again, the following is the answer: Let P be the fixed end of the string, and choose the instant at which,





had the string continued, the disturbance would have been B V A. Make a disturbance H A′ equal and opposite to G A, and let it be compounded with G V B, on the supposition that it is part of a disturbance proceeding from P, such as would by itself bend the string in the opposite direction. Then P V B or P V A′ is the state of the string at that instant. In fact, the disturbance is converted into an equal and opposite disturbance proceeding in the contrary direction.

Now let us suppose a string like that of a pianoforte, sharply struck near one end. It is altogether a gratuitous assumption, knowing what we do of the imperfect elasticity of matter, to suppose that the disturbing effect of the blow immediately affects the whole string. A certain disturbance is produced upon a part (it may be a very small part) of the string. Then what is that perceptible phenomenon, the reiteration of which produces a musical tone? Let us suppose the string struck at one-fourth of the length from its end, and suppose that the tension is such that disturbance is propagated at the rate of 2000 feet a second, the length being four feet. A disturbance is produced at M, from which two simple disturbances begin to travel towards P and Q, at which they are reflected with the same velocities. They will be at N together producing a disturbance (now recompounded) of the same amount as before, but on the opposite side of the string. This takes place while four feet are described at 2000 feet per second, or is repeated 250 times per second. From M to N there is then a succession of effects upon the air, which are most powerful at M and N, owing to the coincidence of the disturbances. This is repeated 250 times in a second, and yields the musical note corresponding to that number of aerial pulsations per second. This is 250 simple vibrations. If we define as a double vibration the time in which the disturbance comes to M again, we should say that there are 125 double vibrations in a second. There is much confusion among writers on this point; some use simple vibrations, or *reversals*; others use double vibrations, or *restorations*.



By supposing the whole string put in vibration, or any simultaneous disturbances communicated to it, the effect may similarly be shown to be, that at the end of the time during which disturbance would be propagated along the whole string the effects are all reversed, but are of the same magnitude; while in a second of such time they are all restored. We thus easily arrive at what is called the fundamental sound of a string. With regard to the harmonics of a string [HARMONICS], they are not so easily shown to be necessary. We shall however, first show that such effects are always possible; that is to say, that if a string begin to vibrate so that its two halves, or its three-thirds, &c., are disturbed together, such an effect will be produced. Suppose, for instance, the initial state of the string to be P M N Q,

where P M, M N, and N Q are the thirds. During the time in which the direct disturbance of P M would be communicated to M N, that of M N would be communicated to N Q, the direct disturbance in N Q would be made retrograde, and so on. Hence though the whole string may vibrate, each of the parts has a vibration by itself in one-third of the time. If we were to modify the vibration of the whole string by compounding with the preceding such a disturbance as would always destroy the velocities at M and N, there would then be three strings, each vibrating in one-third of the time of the whole string. The ear can appreciate such contemporaneous sets of vibrations, and accordingly in this case perceives both the fundamental note of the string and the twelfth above it. If a large and miscellaneous set of disturbances be communicated at once, those only will exhibit cycles of effects which make the halves, the thirds, &c., vibrate together, and we can say little more without entering into mathematics. But in a string it may always be observed that we seldom hear the octave of the fundamental note, and generally the twelfth and seventeenth. No reason can be given for this which is perfectly unobjectionable; we do not know whether it is the aptitude of the ear to distinguish these, or of the string to take the corresponding divisions, which is the cause of the phenomenon.

The time of simple vibration of a string, that is, of complete reversal of all the initial effects, is $l \div \sqrt{2gc}$, where l is the length, and c is as before. It is therefore directly as the length and inversely as the square root of the tension; results which are amply confirmed by experiment.

In all that has preceded we have supposed the string perfectly elastic, and without friction. Neither of these suppositions is true, but since the velocity of propagation of every disturbance is independent of its extent, the gradual diminution of the latter will not affect the phenomenon on which the musical qualities of the string depend.

The method of observing the curves in which each point of a string vibrates, recommended by Dr. Young, was to use a string round which small wire is coiled, like the larger string of a violoncello, and to observe with a microscope the reflection of a candle or other bright spot on one of the coils. Sir J. Herschel suggests that a thin slit should be made in a window-shutter, and that the string should be placed with the point to be examined cutting the vertical plane of light. This point would therefore appear bright while the rest is dark. In either case the rapidity of the vibrations would make the curve described by the bright point permanent.

A single string fitted up for experiments is called a MONOCHORD.

CORDELIERS, so named from wearing a knotted cord for a girdle, were the strictest branch of the Franciscan, or Gray, or Barefooted Friars, established towards the end of the 14th century. Chaucer mentions them in the 'Romaunt of the Rose,' l. 7461. There were ultimately in France, according to Moreri ('Dict. Historique'), no fewer than 284 male and 123 female convents of Cordeliers. A political society, who were opposed to the Jacobins during the French revolution, also assumed this title, from having held its meetings in an old Franciscan convent.

CORDIALS. The beverages known by this name are made of ardent spirits, flavoured with sweetening and aromatic substances. A distiller who produces raw spirits from corn or malt, is not allowed by the excise laws of this country to give any additional or artificial flavour to his spirit; he must sell it in the crude ardent state in which it leaves the still. This is not done out of any consideration in which the consumers are concerned, but simply as a matter of revenue. The distillers rarely if ever sell spirit to the public generally. It is sold to the *rectifiers*, who re-distil it, and impart flavour to it by various means. Cordials are among the liquors which are so treated. Some are made simply by adding essential oils and syrup to diluted spirit; while others are made by adding aromatics to the spirit, boiling and re-distilling it, and sweetening the re-distilled liquor. Some cordials are made from raw spirit, but the best from rectified spirit of wine.

The various cordials are known by the names of the vegetable substance to which they chiefly owe their distinguishing flavours. Hence we hear of aniseed, caraway, cedrat, cinnamon, citron, clove, coriander, lemon, lovage, orange, peppermint, and other cordials.

CORDON, a military term to denote a line of posts and sentries placed around a district or town to prevent any communication between it and the rest of the country. It is chiefly resorted to in cases of any contagious disease having broken out in a place, when it is called a cordon sanitaire; and in order to be effectual, each sentry ought to be able to see his two next comrades right and left.

Cordon in French means also the insignia of an order of knighthood, answering to the English word riband when taken in a similar sense; "cordon bleu," "blue riband," &c.

CORIANDRUM SATIVUM, *Medical Properties of*. This umbelliferous annual plant is a native of the south of Europe, Tartary, &c.,

and much is imported from the Levant, though a considerable portion is cultivated in Suffolk and Essex, for the use of confectioners in this country. The officinal part is the fruit, improperly called the seed. This is round, white, not unlike a grain of white pepper, and was used as a means of comparison for the manna with which the Israelites were fed in the wilderness. (See 'Exodus' xvi. 31, and 'Numbers' xi. 7.) The fresh fruit has a disagreeable odour, which disappears on drying, leaving a pleasant and peculiar one. The taste is warm and aromatic. The potency depends upon the quantity of volatile oil. Ten pounds of fruit yield six drachms of volatile oil. This oil, which is of a yellowish colour, is not in the Pharmacopœia, but it may be used in the same way as the other distilled waters or oils, as a carminative. Coriander was thought better to disguise the odour and taste of senna than other aromatics, but in the infusion ginger is now substituted for it. Making the infusion with cold water is preferable to either, and avoids the tendency to griping. Coriander is retained as an ingredient of the Confectio Sennæ.

It is necessary to guard against confounding coriander with the seed of the *Daphne Mezereon*, called *Semen Coccognidii*, as the latter is very poisonous.

CORINTHIAN ORDER. [COLUMN.]

CORINTHIANS, ST. PAUL'S TWO EPISTLES TO THE. The First Epistle of St. Paul to the Gentile and Jewish converts to Christianity in the city of Corinth is generally considered by the commentators and critics to have been written A.D. 57-8. Of this opinion are Michaelis, Mill, Whitby, Pearson, Benson, Paley, Adam Clarke, Greswell, &c.; but the date assigned to it by Beausobre, L'Enfant, and Lardner is A.D. 56. The first date appears to be the more correct, for in chap. xvi. v. 8, St. Paul announces his intention of remaining in Ephesus until Pentecost; he then went to Macedonia ('Cor.' ii. ch. ii. 13), and this would bring him to the third or beginning of the fourth year of the reign of Nero, or A.D. 57. The place from which it was written is stated in the concluding postscript to be Philippi, which, as it apparently contradicts the apostle's statement in verse 8, "I shall remain in Ephesus until Pentecost," (ἐπιμενῶ δὲ ἐν Εφέσῳ), the latter place is commonly given as the more probable; especially as these postscripts appear to be in other instances erroneous, and without authority.

In order clearly to perceive the design of these epistles, it is necessary to observe the following circumstantial facts which gave occasion to the writing of them: Christianity was first preached at Corinth by St. Paul, who resided there about eighteen months, between A.D. 51 and 53. His successors were Apollos, Aquila, and Sosthenes. But shortly after his departure several other learned and eloquent teachers of Christianity drew away most of the Christian converts from the Gospel doctrine as set forth by St. Paul, and formed them principally into two separate parties, the one contending for the rigid observance of the Jewish ritual, the other for indulgence in some of the idolatrous and lascivious customs of the worship of Venus, to whom a magnificent temple, containing a thousand prostitutes (Strabo, Casaub., 378), was dedicated in the centre of this great commercial city, which bore a proverbial character for luxury and licentiousness. Some writers conjecture that the Judaizing preachers of the Gospel in Corinth were some of the twelve apostles; since Paul asserts that on this question he withstood Peter to the face, and (2 Cor. xi. 22, 23) he speaks of these teachers as Hebrews and ministers of Christ. On being apprised of this condition of the Corinthian church, St. Paul wrote his first epistle, the contents of which may be considered under two general heads; first, the reproval of abuses and corruptions which disgraced the Christian community of Corinth; secondly, the reply to various questions, for the decision of which the Corinthians had appealed to the judgment of their apostle. After commencing with the usual salutation, he proceeds therefore to rebuke their schisms and assumption of knowledge and wisdom; exhorting them to become united to himself, as having a prior claim to their respect and attention (c. i. to iv.). He next reproves them for not having delivered unto Satan one who had his father's wife (c. v.); for not suffering themselves to be defrauded rather than go to law; and especially for their indulgence in fornication (c. vi.). Then follow answers to the questions, in which instructions are given concerning marriage, celibacy of virgins and widows, the eating of idolatrous sacrifices, the exercise of supernatural gifts, the proprieties to be observed by public preachers, and the forbidding women to address congregations (c. viii. to xiv.). A censure is passed upon the profane observance of the Lord's Supper, for in eating it, each before another took his own supper, so that while one was hungry another was drunk (ἕκαστος γὰρ τὸ ἴδιον δεῖπνον προλαμβάνει ἐν τῷ φαγεῖν· καὶ ὃς μὲν πεινᾷ, ὃς δὲ μεθύει) c. xi. 21. From c. xv. 12, it appears that it was taught among the Christians of Corinth that there is no resurrection of the dead. St. Paul thence takes occasion to expatiate upon the subject to the end of this chapter, which forms the most imposing part of the Church of England Burial Service. The epistle closes with an exhortation to the Corinthians to secure the collection of money for the necessitous saints in Judæa, both hearers and preachers, which is several times enforced with various arguments, especially in c. ix. and xvi., and in c. viii. and ix. of the second epistle, of which we now come to speak.

It is generally agreed that the Second Epistle to the Corinthians was written in 58, about a year after the first, and from Philippi, as the postscript asserts. The main purpose of St. Paul in this epistle was to repel the imputations which it appears his first epistle had induced the opponent teachers to make, alike as to his doctrines, authority, and personal appearance. It is in fact an apologetic oration, in which the apostle enlarges on his spiritual office, power, and qualifications; and speaks of his supernatural revelations, as far exceeding the pretensions of his rivals at Corinth, whom he designates "false apostles, deceitful workers, and ministers of Satan," xi. 13. He explains at length the cause of his not having visited the Corinthians as he promised, declares his great success in preaching, mentions his numerous sufferings and disasters incurred for the sake of the faithful, enforces the necessity of completing the contribution for the saints, and concludes with a farewell salutation.

The great rhetorical merits of this address are critically discussed in the 'Disputatio Inauguralis de alterâ Pauli ad Corinthios Epistolâ,' by M. Royards, 8vo, 1818. All the passages in the fathers of the first three centuries which contain any citation from, or allusion to, these two epistles of St. Paul, are collected in the 2nd vol. of Dr. Lardner's Credibility. The words in the first epistle, Ἔγραψα ὑμῖν ἐν τῃ ἐπιστολῇ (c. v. 9), have been the subject of great controversy, as implying that another epistle, not now extant, was written before the one which is called the first. A long list of the critics and divines who have given opinions about it, may be found in Horne's 'Introduc.,' vol. iv. p. 353. Numerous critical particulars may be found in the following works: Michaelis, 'Introduction to the New Testament,' by Bishop Marsh, vol. iv.; Eichhorn, 'Einleitung in das Neue Test.,' vol. iii.; 'Macknight on the Epistles;' Horne's 'Introduction,' vol. iv.; Greswell, 'Harmony of Gospels,' vol. ii.; Paley's 'Horæ Paulinæ;' Barnes, 'Notes Explanatory and Practical on the Epistles to the Corinthians and Galatians;' Jäger, 'Erklärung der beiden Briefe der Apostels Paulus nach Corinth;' Näbiger, 'Kritische Untersuchungen über den Briefe des Apostels Paulus an die Korinthische Gemeinde, mit Rücksicht auf die ihr herrschenden Streitigkeit,' Breslau, 1847. Critical commentaries by Piscator, Rollock, Schlater, and others, are enumerated in Watts' 'Bibliotheca,' where a very copious list is given of sermons on texts from these Epistles, both of which were first printed separately from the Testament by Melancthon at Wittenberg in 1521.

CORK; CORK-CUTTING. The substance commonly known as cork is the outer bark of an evergreen oak, which grows abundantly in Portugal, Spain, the south of France, and Italy. The greatest quantity of cork-bark used in Europe is supplied by Spain and Portugal, but that which is of the best quality is grown in France.

Cork was known and used by the Greeks and Romans, the latter of whom sometimes employed it as we do, for the stopping of casks, and also for the soles to women's winter shoes. (Plin. xvi 8.)

The careful removal of the outer bark from the cork-tree does not in any way injure it, as this outer bark is really dead bark; on the contrary it is stated that the tree grows more vigorously and lives longer, in consequence of being thus stripped. This operation is first performed when the tree is about fifteen years old, and may be repeated once in every eight or ten years.

The bark obtained by the first stripping is of little or no value; but the produce becomes greater in quantity and better in quality at each successive cutting. The months of July and August are chosen for performing this operation. A cork-tree, thus periodically barked, will live for a century and a half. The inner bark contains a considerable proportion of tannin, but it cannot be removed without killing the tree. This destructive plan is resorted to in Corsica, where the cork-oak is indigenous and abundant. Vast numbers of the trees are cut down every year, the outer bark being used as cork, which, however, is not of good quality: the inner bark being sold, principally at Marseille, to the tanners; and the trunks and branches being burned for the sake of the ashes. It is usual, when cork-bark is taken from the trees, to char it slightly, in order to improve the texture by closing the pores; but this burning occasions that peculiar and disagreeable empyreumatic flavour which is so frequently imparted to liquors which have been stopped by cork thus treated. Some years ago an attempt was made to avoid this evil by using cork-bark which is not so old, the texture of which is so close as not to need the aid of fire; but this bark is too thin for ordinary purposes, and could only be used by cementing two or more layers of it together. The risk of bad flavour was by this means altogether avoided; but, for some reason or other, the plan has not been persevered in.

Cork is light, porous, readily compressible and very elastic. The first-mentioned of these qualities, its lightness, occasions it to be used as floats for fishing-nets, &c. For its more general employment, that of stopping bottles, it is peculiarly fitted by its compressibility and elasticity, while its pores are sufficiently minute to prevent the passage through them of the fluids which it is meant to confine.

In making corks by the ordinary method, the material is entirely shaped by very sharp, smooth-edged broad knives, without the aid of any machinery; it is one of those employments in which everything depends on the manual skill gradually acquired by the workman.

The attempts to make corks by machinery have been very numerous. In one among several American patents for this purpose the quadrangular pieces of cork, cut to proper lengths, are held between two revolving spindles which grip them; and as they revolve, the cork is cut round by a revolving cutter-wheel, the arbor of which is horizontal and has its bearings in a sliding frame. Other apparatus allows the spindles to disengage the cork when cut. The edge of the cutter-wheel is kept sharp during the operation by means of two rotating discs, one acting on each face, and each covered with leather and emery. The blocks or pieces of cork are placed in a box, from which they are taken by a jaw which slides forward and places them between the grips of the revolving spindles.

Another plan was patented a few years ago by Messrs. Cutler and Hancock. A horizontal spindle, running in suitable bearings, carries a hollow conical cutter at each end. The largest end of the cone, which is outwards, is made very sharp; and a small opening lengthwise of the cutter has also a cutting edge, for reducing the cork to a proper size and shape, as it enters the cone. A convenient number of these spindles are mounted in a frame, to which a traversing motion can be given by means of a screw and handle. A rapid motion is communicated to the spindles by a number of belts from a large drum moved by a steam engine or other source of power. Pieces of cork are placed in a holder; and the holder being placed in front of the cutters, with a proper support behind, they are urged forward by the hand screw until the cork has been cut through. The corks, as they are made, are pushed out by rods, which slide within the spindles.

Mr. Gilpee's patented machine for cork cutting, has a cutting blade which has a horizontal reciprocating motion, and which acts upon pieces of cork grasped by rotating holders. Harris's patented apparatus contains a circular toothed cutter, mounted horizontally with a circle of holders; pieces of cork are put into the holders, and the holders receive modified movements while the cutter revolves.

A "Patent Cork Cutting Company" was established a few years ago, for the manufacture of corks by machinery. The patentees averred that the corks so made were both cheaper and better than those made by hand. The same company manufactured cork gun-wadding, used in military services. The speculation was not however successful.

Many substitutes for cork have from time to time been introduced, as stoppers for bottles. Mr. Brockedon has invented bottle-stoppers made of India-rubber. The core of the stopper is made of cotton twisted into strands; several of the strands, lapped with flax thread, are laid together longitudinally, with loose fine cotton roving laid between them. They are then lapped in a cylindrical form with flax thread, and the India-rubber solution applied to it while warm. It is only for peculiar purposes that these stoppers can be used as substitutes for corks; when applied, they must be slightly wetted to make them slide down the inner surface of the neck of the bottle.

Messrs Betts have introduced metallic capsules for covering the mouths of corked bottles. [CAPSULES.]

One of many modes suggested of employing cork for stuffing beds and cushions is that patented a few years ago by M. Bachelard. According to this suggestion, the cork is used in the state of saw-dust or shreds, instead of in bulk. Any mode of preparing it may be adopted, provided the cork be in very small fragments. It may be used alone, or combined with wool or horsehair. The patentee states that if a substratum of the cork be covered with a layer of horse-hair or wool, we shall have all the smoothness of a horse-hair or wool mattrass, combined with the lightness and elasticity of cork. When used at sea, such a mattrass might be light enough to act as a life-preserver, in case of exigency. Mr. Ritchie has introduced an ingenious mode of using cork in beds, mattrasses, &c.; and also in hats.

CORN-LAWS AND CORN-TRADE. From a very early period of our history the corn-trade of the country was the subject of legislative interference and restriction. At first, and while the kingdom was thinly peopled, it was deemed good policy, in order to insure a sufficient supply of food for its inhabitants, to forbid the exportation of corn, while its importation was freely permitted; but, in later times, during which the population had increased with a rapidity rarely seen in long-settled countries, the policy of the legislature was altogether different. The object then sought was to stimulate home production by prohibiting importation, or by restricting it in such a degree as to secure to the native farmers a monopoly of the home market, and its ultimate aim was professed to be the securing of a constant sufficiency of a principal article of food, independent of all foreign countries, by means which should insure to the home grower an adequate return for the capital and skill employed. It needs no argument now to show that the policy of our ancestors was ill calculated to insure the end which they had in view, that of providing a sufficiency of cheap food for the common people.

The earliest statute extant upon this subject is the 34th Edw. III., c. 20, passed in 1360-61, by which it was enacted, that "the passage of corn shall be prohibited in all the ports of England, so that none have licence nor warrant to pass with such corn in anywise, unless it be to Calais or Gascoigne, or to other special places which it behoveth that the king cause to be furnished with the corn of England, and that at his own ordinance and licence."

The phraseology of this act has led to the supposition that exportation was previously illegal, except with a licence from the king, and that the object in framing this law was to define and restrict the royal prerogative in this particular. In 1394 another act was passed (17 Richard II., c. 7) of a somewhat contrary tendency. By this new law licence is granted by the king—such are the terms of the act—"to all his liege people of his realm of England, to ship and carry corn out of the said realm, to what parts that please them, except to his enemies, paying the subsidies and devoirs thereof due, notwithstanding any ordinance, proclamation, or any defence (prohibition) made before this time to the contrary; nevertheless he will that his council may restrain the said passage when they shall think best for the profit of the realm." This act was confirmed in 1425 by the act 4 Henry VI., c. 5. Eleven years later it was thought necessary to fix a limit in regard to the price at which the liberty to export should cease, and that limit was declared (15 Henry VI., c. 2) to be 6*s.* 8*d.* per quarter for wheat, and 3*s.* per quarter for barley. This act was passed for only a limited time, and had expired, when, in 1441, on the meeting of parliament, it was renewed in the following terms: "Our sovereign lord the king, forasmuch as this statute is not now in his force, and that many counties adjoining to the sea may not sell the substance of their corn but by carriage and bringing by the sea, hath ordained, that the statute and ordinance aforesaid, now expired, shall begin to hold his force at the Feast of the Nativity of our Lady next ensuing, and shall endure from thence till the parliament next to be holden after the same feast, so that a parliament be holden within ten years next ensuing after the first beginning of this present parliament, and if so that there be no parliament holden within the same ten years, that then it shall continue and endure till the end of the same ten years:" in 1444 this act was "ordained to be perpetual, and stand in his force for ever" (23 Henry VI., c. 5).

The limited permission thus given to export their produce must be attributed to the increasing power of the land owners; and it may be taken as evidence that the cost of production in this kingdom was at least equally moderate with the cost in neighbouring countries, that in all this time no attempt was made to prohibit or restrict the importation of the produce of other countries. Such a restriction was, however, imposed in 1463 by the statute 3 Edward IV., c. 2, which on the plea that "the labourers and occupiers of husbandry within this realm of England be daily grievously endamaged by bringing of corn out of other lands and parts into this realm of England, when corn of the growing of this realm is at a low price," enacts that "no person, from the feast of Saint John the Baptist next ensuing, shall bring into England any wheat, rye, or barley, not of English or Irish growth, unless the price of wheat shall exceed 6*s.* 8*d.* the quarter, that of rye 4*s.*, and that of barley 3*s.*, on pain of forfeiture of the grain." The statutes here mentioned, by which the prices were established at which the importation and exportation of corn were respectively to cease, continued in force until 1534, when a new act (25 Henry VIII., c. 2) prohibits, except by licence from the crown, the exportation of grain, the reason for which alteration is thus quaintly expressed in the preamble to the act: "Forasmuch as dearth, scarcity, good, cheap, and plenty of cheese, butter, capons, hens, and other victuals necessary for men's sustenance, riseth and chanceth of so many and divers occasions that it is very hard and difficile to put any certain prices to any such things, no person or persons, unless it be by licence under the king's great seal, from henceforth shall carry or convey any corn, beeves, muttons, veals, porks, or any other of the above said victuals to any parts beyond the sea, except only for the victualling the towns of Calais, Guinnes, and the marches of the same, and except for victualling of ships passing the seas." The civil wars which preceded the accession of Henry VII. had caused much land to be thrown out of cultivation, and the act of 1534 was probably occasioned by the consequent diminution of produce, but this attempt failed, as it necessarily must, to increase the supply of grain, which effect would best have been brought about by a removal of all restriction. Such a course would have ill agreed with the imperfect ideas upon such subjects which then prevailed; but as the evil was increased during the next seventeen years, and it was thought necessary to apply some remedy, the statute 5 & 6 Edward VI., c. 5, was then passed. This statute is entitled, "An act for the maintenance and increase of tillage and corn," and it enacts that thenceforth at least as much land should be tilled in every parish as had been under the plough at any time since the accession of Henry VIII., under a penalty, to be exacted from the parish, of 5*s.* for every acre that should be deficient. The general permission to export grain, which had been taken away in 1534, was restored in 1554 (1 & 2 Philip & Mary, c. 5), whenever the prices were at or under 6*s.* 8*d.* per quarter for wheat, 4*s.* for rye, and 3*s.* for barley. The preamble to this act makes it appear that it was passed, not in consequence of the prevalence of any sounder views of public economy, but because it was found impossible to prevent exportation, and it was thought that better success would attend the regulation than the prohibition of the trade. In 1562 an alteration in the law was made, by enlarging the limits of the prices which governed exportation, and these were fixed at 10*s.* per quarter for wheat, 8*s.* for rye, and 6*s.* 8*d.* for barley; and nine years later it was enacted (13 Eliz., c. 13) that corn might be exported on payment of certain specified duties at all times when no proclamation had been issued to the contrary. The law of 1463 had all this time been in existence, prohibiting importation while the prices of wheat, rye, and barley should be under 6*s.* 8*d.*, 4*s.*, and 3*s.* respectively; but the prices that had for some time prevailed rendered this law inoperative, and the law of 13 Elizabeth therefore gave virtual freedom to the trade in corn.

In the succeeding reigns, and up to that of William and Mary, this system was continued, but accompanied by various modifications as regards the limiting prices and the rates of duty chargeable. The prices at which export was permitted were from time to time enlarged, until, in 1670, wheat might be shipped away at any time when the price did not exceed 53s. 4d. per quarter. At the same time import duties were imposed, so heavy as to amount to a prohibition, the object of those regulations being to keep the price of wheat always as high as 53s. 4d. per quarter for the advantage of the land-owners. Not satisfied, however, with this degree of favour, this powerful class succeeded in 1689 in procuring an Act (1 Will. & Mary, c. 12) whereby they secured the payment of a bounty amounting to 5s. per quarter on the exportation of wheat when the price did not exceed 48s. per quarter; and bounties according to the same scale were granted for the export of barley and other grain.

Not content with interposing obstacles to a free trade in corn with other countries, our ancestors thought fit to place restrictions upon that trade within the kingdom. It was imagined, that if the consumers could be brought to deal immediately with the growers, the profit of intermediate dealers would be saved. Under this impression, both parties looked unfavourably upon those dealers; the sellers imagining that they could obtain better prices, and the buyers that they could purchase cheaper but for the middlemen, while the common people were easily led to believe that the dearths which then frequently occurred were attributable to the practices of the dealers in buying up corn and withdrawing it from the market. An Act was passed, declaring it to be an offence to buy corn in one market with intent to sell it again in another; and persons guilty of this offence, to which the name of *engrossing* was given, were punished with imprisonment and the pillory. By a statute of Elizabeth, no person was permitted to convey corn from one part of the kingdom to another, unless he had a licence for the purpose, the right of granting or withholding which was confided to the magistrates in quarter sessions. These restrictions were modified in 1624, and by the act 15 Charles II. c. 7, the engrossing of corn was made legal whenever the price of wheat did not exceed 48s. per quarter. So recently as the year 1800, when the price of wheat exceeded 100s. per quarter, engrossing however has been held to be an offence at common law, and a corn-dealer was convicted of it, but was not brought up for judgment.

The Act of 1689 was modified in 1773, by reducing to 44s. per quarter the price at which the payment of bounty was to cease, and in 1815 the granting of bounty was discontinued by law. In fact no bounty could have been claimed at any time after 1792, in which particular year the average price for the whole year was below the price fixed in 1773. At that time (1773) importation was permitted upon payment of the nominal duty of 6d. per quarter whenever the price should be above 48s. This permission was considered injurious to their interests by the land-owners, who, on the plea that the country might become dependent upon foreign countries for its supply of food, succeeded in 1791 in obtaining an Act whereby the price at which importation was allowed at 6d. per quarter was raised to 54s., a duty of 2s. 6d. was imposed when the price was between 50s. and 54s., and 24s. 3d. per quarter was charged when the price was below 50s. A new law, passed in 1804, shifted the price at which the prohibitory duty of 24s. 3d. was charged to 63s.; between that price and 66s. the duty was 2s. 6d.; and above 66s., only 6d. per quarter. Under the Act of 1791, the maritime counties of England were divided into twelve districts, and importation and exportation were regulated in each district by their respective prices; but in 1804 this plan was altered, and the aggregate average of the twelve districts was taken as the measure for regulating importation and exportation to and from the kingdom.

A bill for raising the duties on importation, which was brought into the House of Commons in 1814, met with so much opposition that it was abandoned; but in the following year an Act was passed, after great opposition, and exciting great clamour on the part of the people, allowing the free importation of corn from foreign countries, in order to be warehoused or re-exported, but forbidding the importation for consumption, unless the average prices were, for wheat, 80s.; for rye, peas, and beans, 53s.; for barley, 40s.; and for oats, 26s. Every description of corn might be brought for consumption from the British colonies, when the prices were,—for wheat, 67s.; rye, peas, and beans, 44s.; barley, 33s.; and oats, 22s. The deficient harvests of 1816 and 1817 raised the prices above these limits, and so much grain was imported free of duty that a considerable surplus was left for future and more abundant years. One of these years of abundance occurred in 1822, and during the next twelve months the prices of grain fell below what they had been in any year since 1792. It was expected, on the part of the land-owners, that the effect of the Act of 1815 would have been to keep the price of wheat steady at or about 80s. per quarter; but this expectation was so far from being realised that, if we except the years of scarcity 1816 and 1817, the average price of the period which elapsed before the system of prohibition was exchanged for that of a graduated duty in 1829, was only 58s. 5d. per quarter. In the mean time, by an Act passed in 1823, the law of 1815 was modified so as to allow of importation whenever the prices were,—for wheat, 70s.; for rye, peas, and beans, 46s.; for barley, 35s.; and for oats, 25s. per quarter; but a duty of 17s. a quarter for wheat (and other rates in proportion for other grain) was to be payable during the first three months of importation, and 12s., &c., thereafter. The prices of corn were never such during its continuance as to bring this Act into operation. In 1825 the importation of wheat from the English colonies in North America was legalised upon payment of a duty of 5s. per quarter, without reference to the price in the English market. In 1826, a long-continued drought caused great apprehensions concerning the coming harvests; and in order to prevent the opening of the ports to fresh importations, and the consequent probable admission of a quantity of corn beyond the actual wants of the country, by which prices would have been affected perhaps for years after, permission was given to the government to admit by proclamation 500,000 quarters of foreign wheat then warehoused in the kingdom.

The inconvenience of the system of alternate prohibition and unlimited importation was at length fully recognised by all parties, and in 1829 an Act was passed (9 Geo. IV. c. 60) to regulate the trade in corn. The principle of this Act was, the constant freedom of importation upon the payment of duties fluctuating according to the average price of grain, decreasing as the price advances, and increasing as the price falls. This was the celebrated "sliding-scale" introduced and carried by Sir Robert Peel. The following table exhibits the scale of duties graduated according to the average prices of the different kinds of grain.

WHEAT.

When the price shall be—				per qr.	
62s.	and under	63s.	per qr.	24s.	8d.
63	,,	64	,,	23	8

72	,,	73	,,	2	0
above 73s.				1	0
under 62s. and not under 61s.				25	8

and in respect of each integral shilling, or any part of such integral shilling, by which such price shall be under 61s., such duty shall be increased by 1s.

OATS.

When the price shall be 25s. and under 26s. per qr., 9s. 3d. duty; and in respect of every integral shilling by which such price shall be above 25s., such duty shall be decreased by 1s. 6d. until such price shall be 31s. Whenever the price shall be above 31s., the duty shall be 1s. Whenever such price shall be under 25s. and not under 24s., 10s. 9d.; and in respect of each integral shilling, or any part of each integral shilling, by which such price shall be under 24s. the duty shall be increased by 1s. 6d.

BARLEY.

When the price shall be 33s. and under 34s. per quarter, 12s. 4d. per quarter duty; and in respect of every integral shilling by which such price shall be above 33s., such duty shall be decreased by 1s. 6d., until such price shall be 41s., and whenever the price shall be at or above 41s., the duty shall be 1s. per quarter. Whenever the price shall be under 33s. and not under 32s., 13s. 10d.; and in respect of each integral shilling, or any part of each integral shilling, by which such price shall be under 32s., the duty shall be increased by 1s. 6d. per quarter.

RYE, PEAS, AND BEANS.

When the price shall be 36s. and under 37s. per quarter, 15s. 6d. per quarter, and in respect of every integral shilling, by which the price shall be above 36s., the duty shall be decreased by 1s. 6d. until such price shall be 46s. When the price shall be at or above 46s., 1s. When the price shall be under 36s. and not under 35s. per quarter, 16s. 9d.; and in respect of each integral shilling, or any part of each integral shilling, by which such price shall be under 35s., the duty shall be increased by 1s. 6d. per quarter.

On the 7th of May, 1841, an abortive attempt was made by the ministry of the day to establish a fixed duty of 8s. the quarter on the importation of foreign wheat. The dissolution of parliament, which took place very shortly after this proposition, was unfavourable to the ministry. However, on the 9th of February, 1842, their successors brought forward a measure for a modification of the corn law of 1828, which was successfully carried, and came into operation on the 29th of April following.

Under the Act 9 Geo. IV. c. 60, which lasted from the 15th of July, 1828, to the 29th of April, 1842, the total quantity of foreign wheat admitted was 13,562,856 quarters and 4,305,150 cwts. of foreign wheat-flour, and, in addition, at a lower rate of duty, 597,700 quarters of colonial wheat and 1,744,591 cwts. of colonial flour. Nearly one-half of the foreign wheat and flour was admitted at the lowest rate of duty, and comparatively little at the higher rates, as the following statement will show:—

Duty at	Qrs. Wheat.	Cwts. Wheat-flour.
1s.	5,783,045	1,758,372
2s. 8d.	2,860,613	862,262
6s. 8d. . . .	1,997,226	519,123
10s. 6d.	820,342	243,120

The average rate of duty was under 6s. the quarter. For the whole period during which this Act was in operation the average price of wheat in England and Wales was 59s. 4d., and the extreme points of fluctuation in the weekly averages were from 36s. 8d. to 81s. 6d., or 122 per cent. The highest yearly average was 70s. 8d., in 1839; and the lowest 39s. 4d., in 1835. In 1838 the duty underwent thirty different changes. The scale of duties was so constructed as to offer great inducements to the holders of foreign wheat to withhold supplies until the duty had reached the lowest point; and a rise in prices, at one particular point, of only one shilling, brought down the duty four shillings. It was often stated that prices were fictitiously raised in order that the dealers might gain by the diminished duty; but the strong motives for all holders of wheat to keep back supplies, operated much in the same way, without any fraud on their part. In a single week, when the lowest duty has been attained, above 1,500,000 quarters of wheat have been liberated from the bonding warehouses, the holders of which had resolutely resisted the prevailing high prices until this object had been accomplished. The following was the scale of prices and rates of duty for foreign wheat and wheat-meal under the Act 5 Vict. c. 14:—

Wheat.						Wheaten Flour or Meal.					
Average per Qr.			Duty per Qr.			Duty per Cwt.			Duty per Barrel.		
s.		s.	£	s.	d.	£	s.	d.	£	s.	d.

The lowest duty in the above scale is not reached by jerks, as in the former one, and the "rest" between 66*s.* and 69*s.* was an important modification. One hundred and thirty-eight new towns were added in the new Act to the one hundred and fifty which returned the average prices under the Act of 1828. From July, 1842, to January, 1843, inclusive, the average price of wheat in the 138 new towns was 53*s.* 8*d.*; in the 150 old towns, 52*s.* 6*d.*; making an aggregate average of 52*s.* 10*d.* The importations of wheat which took place under the Act 5 Vict. c. 14, from April 29th, 1842, to 5th April, 1843, were:—

	Foreign.	Average Duty.	Colonial.	Average Duty.
Wheat . .	2,623,478	8*s.* 5*d.*	37,886	1*s.* 11*d.*
Wheat-flour, cwts.	524,491	2*s.* 11*d.*	602,868	0*s.* 7*d.*

Under the Act of 1828 the duties on colonial wheat were 5*s.* when the price here was under 67*s.*, and 6*d.* when at or above 67*s.* the quarter. The Act 5 Vict. c. 14, fixed the duties on colonial wheat as follows: When the price here was under 55*s.* the quarter, the duty was 5*s.*

55*s.*	and under	56*s.*	. . . . duty	4*s.*
56*s.*	,,	57*s.*	. . . . . ,,	3*s.*
57*s.*	,,	58*s.*	. . . . . ,,	2*s.*
58*s.* and upwards			. . . . . ,,	1*s.*

All the efforts, however, to maintain corn at an equable price were vain. At length, in 1845, the potato-rot in Ireland created serious apprehensions of a famine in the United Kingdom, close approaches to which had already been felt in Ireland. On November 22, Lord John Russell wrote a letter from Edinburgh declaring himself in favour of a total repeal of the corn-laws. On December 4, the 'Times' announced that the ministry had resolved to assemble Parliament early to take the corn laws into consideration, with a view to their abolition; but on the 10th, the ministers resigned, and Lord John Russell received the Queen's commands to form a new administration. This, in the face of a parliament elected almost for the purpose of sustaining protection, he was unable to effect, and on Dec. 20, Sir Robert Peel re-accepted office. In the meantime the Anti-Corn-Law League commenced its operations, and numerous meetings were held, at which Mr. Cobden and Mr. Bright attended, and large subscriptions were raised, in order to effect their object of promoting freedom in the corn trade. Meetings were also held by large bodies of labouring agriculturists, and on Jan. 3, 1846, addresses were presented to the Queen by the corporations of London and Dublin praying her to open the ports for the importation of corn duty free. On Jan. 22, the parliament was opened by the Queen, who, in her speech, after alluding to the failure of the potato crop, noticed the prosperous state of the revenue as a proof of the wisdom of former measures passed for the relaxation of protective duties, and suggested whether the "principle might not be yet more extensively applied," and further reductions and remissions made. On Jan. 27, in a committee of the whole House, Sir Robert Peel developed his plan for removing all the restrictive duties on the importation of corn, and substituting instead a fixed duty of one shilling per quarter on all corn imported, whatever the price might be, and at the same time reducing and modifying the duties on other articles of food. A vehement opposition was raised against the measure in the House of Commons, which, during its progress, degenerated into violent attacks on the personal character and motives of Sir Robert Peel; but after a series of debates and several divisions, the third reading was carried on May 15, by 327 votes against 229. On May 18, the bill was introduced into the House of Lords by the Duke of Wellington, and after a series of animated debates, and in the face of an earnest opposition, it was passed on June 25, without a division, the opponents having been outvoted on several amendments that had been proposed by them during the discussion. The bill received the royal sanction on June 26. On the 25th Sir Robert Peel had been defeated on the Protection to Life in Ireland Bill, and on the 29th he announced his resignation, having succeeded in carrying this most important measure.

It will have been seen that for a long series of years England exported grain, and efforts were made to encourage the exportation. In 1689, an Act was passed allowing a bounty of 5*s.* per quarter when exported, if the home price did not exceed 48*s.* per quarter; but in 1773 the home price was reduced to 44*s.* per quarter before the bounty was allowed. This bounty was not abolished by Act till 1815, though the price at home had been so high as to negative its effects, except in 1792, when the yearly average was only 41*s.* 9*d.* per quarter. In fact, from 1790 England ceased altogether to be an exporting country. In 1800 and 1801, there were two bad harvests, and in the latter year wheat reached the unprecedented price of 115*s.* 11*d.* per quarter, and the quantity imported in the two years was 2,638,866 quarters. This occasioned a greater cultivation of land, and from 1800 to 1809 there were 847 inclosure bills passed. In 1810 there was another deficient harvest, and 1,491,341 quarters were imported. In 1812, though the price of wheat advanced to 122*s.* 8*d.* per quarter, only 244,385 quarters were imported. In 1818, on the contrary, when the average price was only 83*s.* 8*d.* per quarter, there were imported 1,503,518 quarters. The framers of the law of 1829 intended it to prevent fluctuations in the price of English grain, but in the seven years, notwithstanding the provision, the price varied from 75*s.* 3*d.* in 1829 to 36*s.* 8*d.* in 1835, descending regularly every year; while in the three years, 1829, 1830, and 1831, there were imported 4,557,736 quarters. In fact, the Act was a total failure, as far as regarded protection to the agriculturist, while it acted very injuriously to the population of the kingdom by artificially raising the price of bread, without any corresponding advantage to the revenue; for the great bulk of the importations was always brought in at a low rate of duty. The total quantity imported, however, kept increasing, with occasional exceptions; but in 1845, waiting the repeal of the duty, the importation was only 1,142,700 quarters, of which only 315,615 were taken for home consumption. In 1846, after the repeal, there were imported 1,437,941 quarters, and 1,995,852 were taken for home consumption. In 1847, there were imported 2,650,058 quarters; besides 6,329,646 cwts. of wheat-meal, 3,614,637 quarters of Indian corn, and 1,451,020 cwts. of Indian corn-meal. In 1848, there were imported 2,594,013 quarters of wheat, 1,765,475 cwts. of flour, and 1,586,781 quarters of Indian corn. In 1849, there were imported 3,872,134 quarters of wheat, 3,371,301 cwts. of flour, 2,247,424 quarters of Indian corn, and 102,173 cwts. of Indian corn-meal. In 1850, there were imported 3,754,593 quarters of wheat, 3,855,050 cwts. of flour, 1,286,264 quarters of Indian corn, and 11,401 cwts. of meal. In 1851, the importations were, wheat 3,833,636 quarters, flour 5,363,478 cwts., Indian corn 1,819,782 quarters, and meal 9,562 cwts. In 1852, they were, wheat 3,068,892 quarters, flour 3,889,583 cwts., Indian corn 1,479,891 quarters, and meal 742 cwts. In 1853, they were, wheat 4,945,314 quarters, flour 4,646,400 cwts., Indian corn 1,552,934 quarters, and meal 15,581 cwts. In 1854, there were imported 3,431,222 quarters of wheat, and 3,646,505 cwts. of flour. In 1855, the importations were, wheat 2,667,702 quarters, and 1,904,224 cwts. of flour. In 1856, they were, wheat 4,072,833 quarters, flour 3,970,100 cwts., Indian corn 1,777,813 quarters, and meal 7,880 cwts. In 1857, they were, 3,417,957 quarters of wheat, 2,178,148 cwts. of flour, 1,150,783 quarters of Indian corn, and 1092 cwts. of meal. In 1858, they were, 4,275,435 quarters of wheat, 3,890,252 cwts. of flour, 1,762,320 quarters of Indian corn, and 4720 cwts. of meal. The average price of wheat per quarter was 69*s.* in 1856, 56*s.* 7*d.* in 1857, and 44*s.* 4*d.* in 1858.

The principal supplies of foreign corn to Great Britain are drawn from Russia, Prussia, Denmark, Mecklenburg, the Hanse Towns, Spain, Turkey, Wallachia, Moldavia, Egypt, the United States, occasionally rather large quantities, especially as flour, from France, some from our own American colonies, and small quantities from various other places. Russia, Prussia, and the United States are the principal contributors. The total computed value of all the corn and meal imported in 1858, including oats, barley, and all the other species, was 19,992,971*l.*

CORN-RENT is a money-rent varying in amount according to the fluctuations of the price of corn. In some countries rent is paid in the produce of the land itself; but in no part of the United Kingdom does this primitive custom exist. Some landlords in Ireland, indeed, for the accommodation of their tenants, were accustomed to accept corn in payment of their rent, at the price of the nearest market, and ship it to England for sale; but the rent is calculated in money. (See Appendix F to 'First Report of Poor Laws (Ireland) Commissioners,' 1836, p. 221.)

A corn-rent is founded upon the principle that a farm being assumed to grow, upon an average, a certain quantity of produce, the value of such proportion of that produce as may be agreed upon shall be paid to the landlord as rent. But as the prices of all produce are liable to considerable variation, and as the profits arising from the land must generally be mainly dependent upon the prices for which the produce is sold, it is supposed to be equitable to the farmer that the money value of that portion of the produce which he pays as rent should be calculated so as to vary with prices, instead of being determined by any arbitrary or unvarying standard. And it is undeniable that with long leases a corn-rent is a security against the growth of any serious disproportion between the rent originally agreed upon and the actual value of the produce of the land. If the farmer, under the security of a long lease, lay out capital upon the land and thus increase the quantity of produce, he derives the entire benefit arising from increased production, as the quantity to be paid as rent has already been agreed upon; and he is secured against loss caused by a fall in prices, as the amount of his rent is governed by prices.

For the purpose of assessing a corn-rent the average price of wheat alone, or of wheat and other grain, is taken—sometimes for the last year, and sometimes for a certain number of years. If the price for one year only be taken, the results to the farmer may be thus stated:—When prices are low from a limited demand for produce, his rent is reduced; and when they are low from increased production, his rent is still reduced, although he has more produce than usual to sell. When prices are high from an increased demand, he has more rent to pay, but the remunerative prices enable him to pay it easily; but when an advance of prices is caused by scarcity, his rent is raised, while the high prices may be counterbalanced by the diminished quantity of produce which he has to sell. Thus in three cases out of four a corn-rent is favourable to the farmer; and even in the fourth case he is secured from loss by its favourable operation in other years. In some leases also a further advantage is given to him by fixing a maximum price: and thus if prices should happen to rise beyond that point, he derives the whole profit accruing from the difference. Under this system of annual averages, so advantageous to the farmer, there is a certain degree of unfairness to the landlord, which is sometimes corrected by assessing rent upon the average price of different kinds of produce for a certain number of years; by which means a just proportion is maintained between the money-rent and the average annual value realised from the land. It is upon this principle that the tithe rent-charges are calculated, from the average price of grain for seven years [TITHES]; and corn-rents are sometimes regulated by the scale of average prices published annually for the purposes of the Tithe Commutation Act. In Wiltshire some farms are let in this manner, but their number is inconsiderable. The rent of grazing and dairy farms cannot be regulated by the ordinary system of corn-averages; but in some of the dairy farms of Cheshire the rent is determined by the average price of wheat and of cheese. In many parts of the south of Scotland corn-rents are paid according to the *fiar* prices of corn, as determined in each county by a jury summoned by the sheriff for that purpose.

The principle of a corn-rent is by no means of recent origin; for by an act 18 Elizabeth, § 6, it was required that in all future leases granted by the colleges in the universities of Oxford and Cambridge, and by the colleges of Winchester and Eton, one-third part at least of the old rent shall be reserved and paid in good wheat at 6*s*. 8*d*. the quarter or under, and good malt at 5*s*. the quarter or under: or shall be paid in ready money after the rate of the best wheat and malt sold at the nearest market.

(*Journal of the Royal Agricultural Society*, vol. v. pp. 84, 177; see also Index to *Report on Agricultural Distress*, 1836.)

CORN-TRADE, ANCIENT. The production of corn, one of the chief necessaries of life, and its commercial exchange, have been a subject of the first importance in all ages. It is proposed here to state briefly the general nature of the trade in corn among two of the states of antiquity to whom we are mainly indebted for our knowledge of the economical condition of ancient times. There are few important political questions at the present day to which we cannot find something similar in former times; and the blunders of ancient legislation may still be instructive to modern statesmen.

Athenian Corn-Trade.—The small and comparatively barren territory of Attica did not produce sufficient corn for the consumption of the inhabitants. Corn was brought into the Piræus, the port of Athens, from the countries bordering on the Black Sea, Syria, Egypt, and other parts of Africa, and from Sicily. Demosthenes asserted (B.C. 355) that the Athenians imported more grain than any other people ('Against Leptines,' c. 9). But the trade in corn between Greece and the Black Sea was of some magnitude at a much earlier date. In B.C. 480, Xerxes, while at Abydos, on his way to the invasion of Greece, saw the corn-ships that were sailing from the Black Sea and through the Dardanelles and carrying corn to Peloponnesus and Ægina. (Herodotus, vii. 147.) Some parts of the country on the coast of the Black Sea now export grain, and probably have exported grain ever since the time of Xerxes.

The importation of grain into Attica was a matter that was protected and regulated by the state; and instances are mentioned of armed ships convoying the corn-vessels from the Black Sea to the Piræus. The exportation of corn from Attica was forbidden; and only one third of the foreign corn that was imported into the Piræus could be re-exported to other countries: this law as to importation was enforced by the overseers of the harbour. The law interfered with the trade in corn in other ways also, with the intention apparently of keeping prices low: but with what success it is easy to conjecture. Engrossing or the buying up of corn was a serious offence: a man could not purchase more than fifty loads (called φορμοί). The amount of these loads cannot be exactly ascertained, nor is it material: the principle is clearly shown by the limitation. The penalty for violating this law was death. Boeckh ('Public Economy of Athens,' Eng. trans.) states the law thus: "In order to prevent the accumulation and hoarding of corn, engrossing was very much restricted; it was not permitted to buy at one time more than fifty such loads as a man could carry." According to this a man might buy fifty loads as often as he pleased at different times. But the meaning of the passage of Lysias is that a man must not buy up corn so as to have on hand more than fifty loads at a time. This interpretation is consistent with the Greek, and the other is not; and it is not open to the same kind of objection that Boeckh's interpretation is.

The absurdity of the Athenian legislation on the trade in corn appears from a speech of Lysias against the corn-dealers (Κατὰ τῶν Σιτοπωλῶν). The corn-dealers were generally aliens, and their business made them objects of popular detestation: it was alleged that they bought up corn, and refused to sell it when it was wanted, and thus compelled the buyers to pay them their own price. Yet it is stated by Lysias that the law was, that a dealer must sell his corn only one obolus dearer (the medimnus?) than he bought it. Thus the law attempted to fix the maximum profit of the dealers. But they evaded the law, according to the same authority, by selling it a drachma (six oboli) higher on the same day: the meaning of the orator here is not quite clear. The orator states that the hope of great gain made the dealers run the risk of the extreme penalty of the law. He urges the court which was then sitting for the trial of some of the corn-dealers whom he was prosecuting, to enforce the penalty against them, and so make them mend their manners; and he represents both the consumers and the importers of corn as suffering from the combinations of the dealers. A more signal instance of absurdity and commercial ignorance is not extant than this oration.

To carry the laws as to the sale of corn into effect, the Athenians had corn wardens (σιτοφύλακες) who kept an account of the corn that was imported, inspected flour and bread, and saw that they were sold of the weight and at the price fixed by law.

Various enactments were made with a view of securing a supply of corn; such as that no money should be lent on a vessel which did not bring back to Athens a return cargo of goods, among which corn was mentioned; and that no person living in Attica should import corn to any place except the port of Athens. The interest of individuals, and ultimately the real interests of the community, were thus set in opposition to the supposed interests of the state, and evasions of the laws are often spoken of. Individuals attempted what they will always do, to sell their grain at the dearest market. (Xenophon, 'Œconom.,' c. 20.)

There were public corn-warehouses at Athens, in which corn was lodged that had been purchased at the expense of the state, and sometimes, as it appears, by private contributions. There were officers appointed to purchase the corn (corn-buyers, σιτῶναι), and persons to give or measure it out (ἀποδέκται). Corn so purchased was probably sold to the people at a low price, and sometimes also there were gratuitous distributions of it, as at Rome; and occasionally, as at Rome also, presents of grain were received from foreign princes or rich persons, and distributed among the people gratis.

This subject has been investigated by Boeckh, 'Public Economy of Athens,' translated by Mr. (now Sir) G. C. Lewis, 2nd edition, revised, 1842; and these remarks are mainly founded on what is said there. The subject is curious, but unfortunately we must collect our information mainly from detached passages of the Athenian orators, who deal largely in falsehood and exaggeration, and it is not possible to arrive at certainty on some points.

Roman Corn-trade.—What we know of the ancient corn-trade of Italy mainly relates to the city of Rome. From an early period it belonged to the administration to see that the city was duly supplied with grain. The immediate neighbourhood of Rome did not supply the wants of the city, and grain was imported into Rome from the country of the Volsci and from Cumae soon after the establishment of the consular government. (Livy, ii. 9.) An importation of corn from Sicily is mentioned by Livy (ii. 41) under the year B.C. 486. As the Romans extended their empire, and provincial governments were formed, such as those of Sicily and Sardinia, supplies of grain were got from foreign parts. After the conquest of Sicily, the proprietors were allowed to keep their lands on condition of paying a tenth of the produce to the Romans, according to the system which had been established by King Hiero. Sardinia, after the conquest, paid the same. (Livy, xxxvi. 2.) The mode of proceeding, as to the tenths in Sicily, was this: the cultivator gave notice of what quantity of land he intended to sow, and an entry was made of it. The Roman state took the tenth of the produce in kind, which the cultivator was bound to convey to some port in Sicily, where it was embarked for Rome. All the wheat produced by the tenths was entered in the public books, and it was all conveyed to Rome or to the armies which were serving in parts remote from Rome; this at least appears to have been the general rule.

Sometimes two-tenths of the produce were claimed by the Roman state (Livy, xxxvi. 2; xxxvii. 2), but in this case the second tenth was paid for out of the Roman Aerarium. Presents of grain from foreign states and princes were sometimes made to the Romans. (Plutarch, 'C. Gracchus,' c. 2.) Thus it appears that the state undertook to provide the chief supply of grain for the city: the grain was sometimes sold, and sometimes distributed gratis among the poor, a practice which became common under the late republic. Besides these distributions of corn at the public expense, the wealthy Romans who sought popularity sometimes made like distributions of corn among the poorer citizens, as M. Crassus the Rich did in his consulship. (Plutarch, 'Crassus,' c. 2, 12.)

It does not appear, then, that the chief supply of corn for the city of Rome during the republic was furnished in the regular way of trade. It was the business of the state to keep the proper supply of corn for the city in the public warehouses; but the supply was not always equal to the demand, and it also often happened that many people could not afford to pay the price. Scarcity was not uncommon both under the republic and the empire.

In Livy (iv. 12) we have a notice of the creation of a Præfectus Annonæ, or superintendent of provision, L. Minucius, B.C. 440, in a season of scarcity. He exercised his office in an arbitrary manner, by compelling persons to state what corn they had in their possession, and to sell it; and he endeavoured to raise a popular clamour against the corn-dealers, if Frumentarii here means private dealers. Cn. Pompeius Magnus was intrusted with the superintendence of provision for five years. (Cicero, 'Ad. Attic.,' iv. 1.) Augustus, at the urgent importunity of the people, took on himself the office of Præfectus Annonæ, such as Pompeius held it. (Dion. Cassius, liv. 1.)

Under the early republic many parts of Italy were well cultivated, and Rome, as already observed, derived supplies of corn from various parts of the peninsula. But the civil wars which devastated Italy near the close of the republic were injurious to agriculture. Murder and proscription thinned the numbers of the people, and life and property were insecure. Many of the lands changed owners, and the property of those who were cut off by violence fell into the hands of others, and chiefly of the soldiers. These and other causes made Italy less productive about the time of the Christian era than it had been some centuries earlier. Even under the peaceable administration of Augustus, 60,000,000 modii of wheat were annually imported into Italy and Rome from Egypt and the Roman province of Africa. The modius is estimated at 1 gallon and 7·8576 pints, English measure. But this did not prevent scarcity: there was a great famine at Rome in the latter part of the administration of Augustus. (Dion Cassius, lv. 26; Vell. Paterc., ii. 104; Suetonius, 'Augustus,' c. 42.) The general administration of Tiberius, the successor of Augustus, is commended by Tacitus. ('Annal.,' iv. 6.) He endeavoured to secure a proper supply of corn by intrusting to the Publicani the management of the tenths of grain from the provinces; but there was a great famine in his time, and the high price of grain almost caused an insurrection. The emperor showed that he had not neglected this important part of the administration: he published a list of the provinces from which corn was brought, and he proved that the importation was larger than in the time of Augustus. (Tacit., 'Annal.,' vi. 13.) Again, under the administration of the Emperor Claudius, a famine in Rome occurred. (Tacit., 'Annal.,' xii. 43.) Tacitus observes, that during the scarcity Claudius was assailed with menaces while he was seated on the tribunal in the forum, and he only escaped by the aid of his soldiers. He adds that there were only fifteen days' provisions in the city; and "formerly Italy used to export supplies for the legions to distant provinces; nor is Italy now barren, but men prefer cultivating Egypt and Africa, and the existence of the Roman people is intrusted to ships and the dangers of the sea." Claudius subsequently paid great attention to the supplying of Rome with corn. Under Nero, the successor of Claudius, there was a famine at Rome. (Suetonius, 'Nero,' c. 45.)

The comparison of ancient and modern prices of grain is a difficult subject, and the results hitherto obtained are not satisfactory. It is also necessary to be careful in considering the circumstances when any prices are mentioned. P. Scipio on one occasion (B.C. 200) sent a great quantity of corn from Africa, which was sold to the people at four ases the modius. (Livy, xxxi. 4.) In the same book of Livy (c. 50) another sale is mentioned at the rate of two ases the modius. But on these, as on many other occasions, these prices were not the market-prices at which wheat would have sold, but they were the lower prices at which the state sold the grain in order to relieve the citizens. Rome, both under the republic and the early empire, suffered occasionally from scarcity or from high prices of grain. It is possible that a supply might have readily been procured from foreign parts if there had been a body of consumers in Rome to pay for it. But the export of grain to Rome was not a regular trade; it was, as above explained, a system by which the Romans drew from their provinces a contribution of corn for the consumption of the capital, and it was not regulated by the steady demand of an industrious class who could pay for it. The reign of Tiberius appears to have been a period of scarcity; the complaints were loud, and the emperor fixed the price of corn in Rome, and he promised to give the merchants a bounty of two sesterces on the modius. This seems to mean that the emperor fixed the prices for all grain, including whatever private merchants might have; but to make them amends for any loss, he paid them part of their prices out of the treasury. After the fire at Rome, in the time of Nero, Tacitus speaks of the price of corn being lowered to three sesterces the modius. The Emperor Diocletian, by an edict, fixed the prices of all articles through the Roman empire. The reason for this measure is stated, in the preamble to the edict, to be the high market-price of provisions, which is attributed to the avarice of the dealers, and was not limited even when there was abundance. (Inscription of Stratoniceia; see an Edict of Diocletian, fixing a maximum of prices throughout the Roman empire, A.D. 303, by Colonel Leake, London, 1826, 8vo.)

It does not appear whether the grain which was brought to Rome from the provinces was brought in public ships, or in private ships, by persons who contracted to carry it. There seems, however, to be no doubt that there was also importation of corn by private persons, and that there were no restrictions on the trade, for the object was to get a full supply. A constitution of Valentinian and Valens ('De Canone Frumentario Urbis Romæ,' Cod. xi., tit. 23) declares that merchants (nautici) were to make a declaration of the grain which they imported before the governors (of provinces) and the magistrates, and that they had only good corn on board; and it was the business of the authorities to see that the grain was good. The provisioning of Constantinople, Alexandria, and probably other great cities, under the later empire, was subject to regulations similar to those of Rome, and there were public granaries in those cities.

It is almost impossible to collect from the scattered notices in the Roman writers a just notion of the nature of the trade in grain. So far as concerns Rome, we can hardly suppose that there was a regular trade in our sense of the term. The chief supply of grain was provided by the state. That which is best left to private enterprise was undertaken by the government. It is true that the condition of Rome was peculiar under the late republic and the empire. The city was full of paupers, who required to be fed by occasional allowances of corn. The effect, however, of the state purchasing for the people was not a certain supply, but occasional scarcity. Whether a state undertakes to buy for the people what they want for their consumption, or regulates the trade by interfering with the supply, is immaterial as to the result. In either case the people may expect to be starved whenever corn is scarce. The Roman system was to import all that could be got into Rome, but it was not left to private enterprise. There was no exclusion of foreign grain in order to favour the Italian farmer; nor can it be said that the Italian farmer suffered because foreign grain was brought into Rome and other parts of Italy; he could employ much of his land better than in growing corn for Rome and sending it there. Corn came from countries which were better adapted to corn-growing than many parts of Italy; and besides this, the transport of grain from many foreign parts to Rome, such as Sardinia, Sicily, and the province of Africa, would be as cheap as the transport of grain by sea from the remote parts of Italy, and much cheaper than the transport by land.

The essay of Dureau de la Malle, 'De l'Economie Politique des Romains,' and the treatise of Vincentius Contarenus, 'De Frumentaria Romanorum Largitione,' in Grævius, 'Antiq. Rom. Thesaurus,' vol. viii., contain most of the facts relating to the supply of corn to Rome; and both have been used for this article.

CORNET, a commissioned officer in a regiment of cavalry. He is immediately inferior to a lieutenant, and his rank corresponds to that of an ensign in a battalion of infantry.

The word is derived from the Italian *cornetta*, signifying a small flag; and hence, both in the English and French services during the 16th and 17th centuries, it was applied not only to the officer who had charge of the standard, but to the whole troop, which seems then to have consisted of a hundred men and upwards, and to have been commanded by a captain.

CORNET, a shrill wind instrument formed of wood, which seems to have been known from the earliest times, and continued in use until the latter part of the 17th century, when it was laid aside for the oboe. In the 'Musurgia' of Luscinius is a rude wood-cut of the cornet; but it is represented in a more satisfactory manner in Mersenne's 'Harmonie Universelle,' from which it appears that the instrument was blown by a mouth-piece, and that there were treble, tenor, and base cornets. The compass of the first was from A, the second staff in the treble, to E in alt. The last was bent in rather a serpentine form, and reached nearly five feet in length, therefore was deep in tone.

CORNET-STOP, in the organ, is an imitative treble-stop, consisting of five ranks of pipes, in organs on a large scale, each key of the instrument causing all the five pipes to sound at once. These are tuned to a given note, its octave, twelfth, fifteenth, and seventeenth, though the whole together produce the effect of a single note. This is a harsh stop, and is now used only in union with others; but formerly, compositions called *Cornet Pieces*, were written exclusively for it; these have been proscribed by an improved taste in organ-playing.

CORNICE. [COLUMN.]

CORNIN. A bitter crystallisable matter, found in the bark of the root of the *Cornus florida*.

CORNS are in the first instance merely thickenings of the cuticle, generally of the toes, arising from continued pressure over a projecting portion of bone. While superficial, a corn is moveable, and retains the lamellated structure of the cuticle; afterwards it acquires a base, attaches itself more firmly to the subjacent parts, and becomes a complete corn. "A bursa or bag of synovial membrane, similar to those bursæ which are of original formation, but of very small size, is formed between the thickened cuticle and the cutis; it is this combination of thickened cuticle with a subjacent bursa which constitutes a perfect corn." Corns are either hard and dry, which is the case when they are situated externally; or they are soft, when situated between the toes. The inconveniences arising from corns are generally slight; sometimes they are very serious. The bursa under a hard corn is apt to suppurate, and the inflammation, pain, and irritation, are excessive. Tight or improperly-shaped shoes being the primary cause of corns, shoes or boots fashioned to the natural shape of the foot must be worn, and the material of which they are formed should be soft and pliant. To avoid pressure upon a corn already existing, a portion of leather spread with diachylon or other emollient plaster having a hole in it corresponding with the size of the corn may be worn; or if the outer portion of the corn, which is quite insensible, be pared or scraped away, temporary relief is obtained. For a corn which has become very sensible, the application of lunar caustic or concentrated nitric acid is necessary; if there be reason to suspect the existence of an inflamed bursa containing pus, the outer portion must be cut away with the scalpel, and the bursa freely laid open, so that the matter may escape, which will give great relief. If a soft corn become very sensible, as it often does, without an abscess existing beneath, concentrated nitric acid should be applied. Bunions differ from corns, inasmuch as the part affected is generally of greater extent; a bursa is always connected with them, and when inflamed, serum is secreted, which, if pressure and all causes of irritation be avoided, is again speedily absorbed. If the bursa be much inflamed, leeches and fomentations are necessary; and should pus have formed, it must be let out. If the abscess do not speedily heal, nitric acid should be carefully applied to its inner surface. Extirpation of corns has been recommended, but it is not free from danger, and should never be attempted except by a very skilful and dexterous person. A wound or laceration of the tendons or fibrous structures around the joints, is sometimes followed by the most alarming symptoms, even by tetanus and death. Amputation of the toe has been practised. (See Sir B. Brodie's excellent Lecture on Corns and Bunions, 'Medical Gazette,' February 13th, 1836.)

CORNUCO'PIA, or CORNU-COPIÆ, the horn of plenty, fabled to have had its origin in the infant days of Jupiter; it was filled with the fruits of the earth, and was endowed with the property of always becoming spontaneously furnished with a new supply. Ovid, in his 'Fasti' (lib. v. 115-128), tells us that one of the goats of Amalthea, who nursed Jupiter in Crete, broke off its horn against a tree, when the nymph, having wreathed it with flowers and filled it with fruit, presented it to the god. Jupiter, when he came into power, called his nurse to the skies, and made the horn the emblem of fertility. The Greeks called it *κέρας Ἀμαλθείας, the horn of Amalthea.* In his 'Metamorphoses' (lib. ix. v. 82, &c.), Ovid derives the origin of the Cornucopia from a different fable. He speaks of it as the horn of the river-god Achelous, broken off by Hercules, and consecrated by the Naiads:—

> "Naïdes hoc, pomis et odoro flore repletum,
> Sacrarunt."

The Cornucopia was the proper symbol of Tyche or Fortune, but it was also carried by the several lesser deities of the Romans who presided over the needs and destinies of the people. In representations of the deities the cornucopia usually rests on the left arm. Only three or four statues of Roman goddesses are known which have the original cornucopiæ remaining; of these one is in the Museum of the Vatican, another in that of Dresden, and a third in the Museum at Naples. Statues of Roman empresses bearing cornucopiæ are, however, not uncommon. On Roman or Græco-Roman relievi goddesses are often represented with cornucopiæ. Cornucopiæ are also often figured on vases in the hands of both male and female deities; they occur likewise very frequently in the types of ancient coins, particularly upon those of Sicily.

The beautiful medal of Arsinoë, wife and sister of Ptolemy II. Philadelphus, Greek king of Egypt, given in the article ARSINOË, in the BIOG. DIV., has a cornucopia on the reverse.

COROLLARY (Corolla, "a little crown,") is frequently used for any necessary consequence of a proposition; but technically applied in geometry, it means a consequence which immediately follows from the demonstration of a proposition, without the necessity of introducing any other proposition. But all the corollaries in our editions of Euclid are annexed by editors, none of them being in the original. Those of book i., prop 32, were added by Campanus; but the first use of the word which we know of is in the English translation by Billingsley.

CORO'NA. [COLUMN.]

CORO'NA BOREA'LIS AND AUSTRA'LIS, the northern and southern crowns. The first is a northern constellation, found in Aratus, who says it was formed by Bacchus in memory of Ariadne. It is situated between Bootes and Hercules, and the bright star of its cluster (marked α) may be seen about an hour eastward of Arcturus, and about eight degrees nearer to the pole. Corona Australis is a southern constellation, first found in Ptolemy. It is situated between the front legs of Centaurus.

The following are the principal stars in *Corona Borealis.*

Character.	No. in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.
β	3	5098	4
θ	4	5131	4
α	5	5143	2
δ	10	5244	4

There are no bright stars in *Corona Australis.*

CORONATION, the act of crowning or consecrating a king. This rite is of remote antiquity, as may be gathered from the notices which we have in Scripture, in the first and second books of Kings, of the coronations of Solomon, and of Joash the son of Ahaziah, of the latter of whom it is expressly said that Jehoiada the priest took him, put the crown upon his head, and gave him the testimony, and they made him king, and anointed him. The act of anointing seems to have originated with the Jews.

In England, after the kingdoms of the Heptarchy had become united, we find the ceremony of coronation continually alluded to in the Saxon Chronicle, under the term ȝehalȝod, by which is expressed that the king was hallowed or consecrated. Kingston-upon-Thames was the place where the Saxon sovereigns were crowned during nearly the whole of the 10th century. (See Diceto and the other historians in the 'Decem Scriptores.') Edgar, who succeeded to the throne in 959, is said to have been crowned either at Kingston or at Bath. Edward the Confessor was crowned at Winchester in 1042. The copy of the Gospels upon which the Saxon kings were sworn at their coronations is believed to be still preserved amongst the Cottonian Manuscripts in the British Museum, in the volume Tib. A. ii. Harold and William the Conqueror were crowned at Westminster. It was customary with the Norman kings to be crowned more than once. Henry II. crowned his eldest son, and associated him with himself in the administration during his own life.

In one or two instances, in the Norman times, we find the regnal years of our kings dated from their coronations only; the previous time, between the predecessor's death and the performance of the inaugural ceremony, was considered as an interregnum. This is a fact of no small importance to those who would accurately fix the dates of public instruments and transactions in the reigns of Richard I., John, and their successors.

The first English coronation of which we have any detailed account is that of Richard I., in the Histories of Diceto and Bromton. (See Twysd., 'Script.' x. coll. 647, 1157.) An account of all the formalities observed at that of Richard II., taken from the 'Close Rolls,' is to be found in Rymer's 'Fœdera,' the old edition, vol. vii. p. 157. Froissart has given a short but interesting narrative of the coronation of Henry IV., which the reader may see in in the English edition of his 'Chronicle,' by Lord Berners, 4to., London, 1812, vol. ii., pp. 753, 754. The details of the English coronations of Henry V. and VI., and of the latter in France, are contained in the Cottonian Manuscripts, Tib. E. viii. and Nero C. ix. Hall and Grafton have described the ceremonies at the coronation of Richard III. The account of the coronation of Henry VIII., with the king's oath prefixed, interlined and altered with his own hand, is likewise preserved in the Cottonian Manuscript already mentioned, Tib. E. viii. The oath, with its interlineations, is engraved in fac-simile in the first volume of the second series of Ellis's 'Original Letters illustrative of English History.' Fuller, in his 'Church History,' and Ellis's 'Letters,' 1st Ser., vol. iii. p. 213, detail the particulars of the coronation of Charles I. Several editions of the Form and Order of Charles II.'s coronation at Scone in 1651 were published at the time in 4to, at Aberdeen; reprinted at London in folio, 1660; and the entertainment of Charles II. in his passage through London to his coronation, with a narrative of the ceremony at the coronation, by John Ogilby, with plates by Hollar, fol., London, 1662. Sandford's 'History of the Coronation of James II.,' fol., London, 1687, illustrated with very numerous engravings, is the most complete of all our works upon English coronations published by authority. That of George IV., of which two portions only appeared, was far more splendid, with coloured plates, but remains unfinished. In this work the oath taken by the sovereign on his or her coronation is given at length.

A very ancient MS. of the ceremonial of crowning the emperors at Aix-la-Chapelle was purchased at the last sale of Prince Talleyrand's libraries, by Mrs. Banks, and is now among the additional manuscripts in the British Museum. Of foreign published coronations that of Charles V. at Bologna as emperor, in 1530, is one of the most curious, engraved in a succession of plates upon a roll of considerable length. The 'Sacre de Louis XV., Roy de France et de Navarre, dans l'Eglise de Reims, 25 Oct. 1722,' is a work of pre-eminent splendour, full of finished engravings. The 'Description of the Ceremonies at the Coronation of Napoleon as Emperor of France, with his Consort Josephine, 2 Dec. 1804,' is a work of equal size, but the engravings are chiefly in outline: folio, Paris, 1807. There is a volume, with engravings, of the coronation of the empress Anne of Russia, fol., Petersburg, 1731; and many others might be enumerated.

The formulary which has served for the general model for the

English coronations since the time of Edward III. is the 'Liber Regalis' deposited in the archives of the dean and chapter of Westminster, and kept with a religious care. It is supposed to have been written for the particular instructions of the prelates who attended at the coronation of King Richard II. and his queen. Copies of this manuscript, without its illuminations, are preserved in one or two of our manuscript libraries. The substance of the ceremonial directed in it is abridged in Strutt's 'Manners and Customs,' vol. ii.

CORONER. The coroner (*coronator*) is an ancient officer by the common law of England. The name is said by Lord Coke to be derived "*a coronâ*, because he is an officer of the crown, and hath conusance of some pleas which are called *placita coronæ*." In this general sense the chief justice of the Court of King's Bench is by virtue of his office the supreme coroner of all England, and may, if he pleases, hold an inquest, or otherwise exercise the office of coroner, in any part of the kingdom. Lord Coke mentions an instance in which Chief Justice Fineux in the reign of Henry VII. held an inquest on the body of a man slain in open rebellion, 5 'Reports,' 51. In this sense also, the Master of the Crown Office in the Court of King's Bench, is styled the "coroner or attorney for the king;" his business being confined to pleas of the crown discussed in that court. But the officers now usually understood by this term are the coroners of counties, who are of high antiquity, being said in one of the most ancient treatises on the common law to have been ordained together with the sheriffs to keep the peace of counties when the earls gave up the wardship. ('Mirror,' c. i. § 3.) In early times too, the office appears to have been one of great estimation; for by the statute 3 Edw. I. c. 10, they are required to be knights, and by the 28 Edw. III. c. 6, they must be "of the most meet and most lawful men of the county." By the 14 Edw. III. st. 1. c. 8, "no coroner shall be chosen unless he have land in fee sufficient in the county, whereof he may answer to all manner of people." No peculiar qualification is now required, though Serjeant Hawkins seems to express an opinion that the persons chosen, though not knights, must be "of good substance and credit." (Hawkins's 'Pleas of the Crown,' book ii. cap. 9.) Most commonly there are four coroners in each county; but the number varies according to the usage of different counties. There have been recent instances in which, upon a representation made to the lord chancellor by the magistrates, that the existing number of coroners was insufficient for the business of the county, writs have issued for the election of additional coroners. (See 3 Swanston's 'Reports,' 181.)

Coroners of counties are elected by the freeholders in the county court, in the same manner as sheriffs and conservators of the peace formerly were; the election takes place by virtue of an ancient king's writ, *De Coronatore Eligendo*, returnable in chancery. The 58 Geo. III. c. 95, which made provision for conducting the election of coroners similar to those then in existence for the election of knights of the shire, was repealed in 1844 by 7 & 8 Vict. c. 92, which substituted other regulations on the ground that the former mode of election was inconvenient and attended with great and unnecessary expense. This Act applies only to county coroners, and the coroners of the city of London and borough of Southwark, of the Queen's household and the verge of the Queen's palace, and Admiralty coroners, are specially exempted. Counties may be divided by the justices into two or more districts for the purposes of this Act, and alterations may be made in existing divisions. The justices, in making such divisions, are in the first place to petition her majesty, and notice is to be given to each coroner by the clerk of the peace of the time when the justices will take such petition into consideration. Any coroner of the county may present a petition to her majesty touching the proposed division or alteration of districts. Her majesty, with the advice of the privy council, may order that such county shall be divided into so many districts as may be considered convenient, and determine at what place within each district the court for the election of coroner for such district shall be held. The justices are to direct the clerk of the peace to make out a list of the several parishes, townships, or hundreds in each of the coroner's districts into which the county is divided, specifying the place within each district at which the court for the election of coroner is to be held, the place or places at which the poll is to be taken, and the parishes or places attached to each polling-place. The justices may then assign one district to each coroner; and whenever a vacancy occurs, the election is to be made in the manner prescribed by the Act. The coroner must reside in the district for which he is elected, or in some place wholly or partly surrounded by such district, or not more than two miles beyond its outer boundary; the election must be made in the district; and the coroner chosen by a majority of persons duly qualified who shall reside in such district; no voter can poll out of the district where his property lies. Within not less than seven or not more than fourteen days after the sheriff shall have received the writ *De Coronatore Eligendo*, he is required to hold in the district for which a vacancy has occurred a special county court for the election; and if a poll be demanded, it may be kept open for two days, eight hours each day, from eight o'clock in the morning. The sheriff is to erect polling booths; poll clerks are to be sworn; and an inspector of poll clerks is to be appointed on the nomination of each one of the candidates. Electors may be required by or on behalf of any candidate to make oath respecting their qualification. The result of the poll is to be declared by the sheriff. The coroner, although elected for a district, is to be considered as a coroner for the whole county; but he is only to hold inquests within his own district, except in case of the illness or unavoidable absence of the coroner for another district; and his inquisition must certify the cause of his holding such inquest.

Coroners in counties are elected for life; but if they accept an office incompatible with the duties, such as that of sheriff, or dwell in a remote part of the county, or are incapacitated by age or infirmity, they are removable by means of the writ *De Coronatore Exonerando;* and by the stat. 25 Geo. II. c. 29, § 6, they may be removed upon conviction of extortion, wilful neglect of duty, or misdemeanour in their office. The great seal has authority however, independently of the above statute, to remove coroners for neglect of duty. (1 Jacob and Walker's 'Reports,' 451.) By the stat. 7 & 8 Vict. c. 92, coroners are prohibited from acting professionally in any case in which they have sat as coroner.

At common law the coroner had authority to hear and determine felonies; but his powers in this respect were expressly abrogated by Magna Charta, cap. 17. The most usual duty of a coroner is that of taking inquisitions of death; and though his duties, as well as his authority in this respect, are said to have existed at common law, they are declared by the 4 Edw. I. stat. 2, commonly called the statute *De Officio Coronatoris.* By the directions of that statute, "the coroner, upon information, shall go to the places where any be slain, or suddenly dead or wounded, and shall forthwith command four of the next towns, or five or six, to appear before him in such a place; and when they are come thither, the coroner, upon the oath of them, shall inquire in this manner; that is to wit, if they know where the person was slain, whether it were in any house, field, bed, tavern, or company, and who were there; who are culpable, either of the act or of the force; and who were present, either men or women, and of what age soever they be, if they can speak, or have any discretion; and how many soever be found culpable, they shall be taken and delivered to the sheriff, and shall be committed to the gaol; and such as be found and be not culpable, shall be attached until the coming of the judge of assize." And it is declared by the same statute, that "if it fortune any such man be slain, which is found in the fields or in woods, first it is to be inquired whether he were slain in the same place, or not; and if he were brought and laid there, they should do so much as they can to follow their steps that brought the body thither, whether he were brought upon a horse or in a cart. It shall also be inquired if the dead person were known, or else a stranger, and where he lay the night before." It is declared also by the same statute, that "all wounds ought to be viewed, the length, breadth, and deepness; and with what weapons; and in what part of the body the wound or hurt is; and how many be culpable; and how many wounds there be; and who gave the wound." In like manner it is to be inquired by the coroner "of them that be drowned, or suddenly dead, whether they were so drowned or slain, or strangled by the sign of a cord tied straight about their necks, or about any of their members, or upon any other hurt found upon their bodies. And if they were slain, then ought the coroner to attach the finders and all other in the company." The provisions of this ancient statute are still in force, and are to be followed by coroners in all their particular directions as nearly as possible at the present day in inquisitions of death. In case of a death happening upon the high sea, inquisitions are taken before the Admiralty coroner, who is appointed by the king or the Lord Admiral; and the county coroners have in such a case no jurisdiction. The inquisitions taken before the Admiralty coroner are returned to the Commissioners of the Admiralty under stat. 28 Hen. VIII., c. 15.

The coroner has authority to assemble a jury by means of a precept to the constables of the hundred or adjoining township, and under the 7 & 8 Vict. c. 92, jurors and witnesses who neglect to attend an inquest may be fined any sum not exceeding 40s. The power, however, of punishing witnesses who refuse to give evidence for contempt of court, and the right to exclude persons from his court, are incidents of his office. When the jury are assembled, they are charged and sworn by the coroner to inquire, upon view of the body, how the party came by his death. The jury are, by the 6 & 7 Will. IV. c. 86, amended by the 21 & 22 Vict. c. 25, to inquire into the particulars required for the registration of deaths, and the coroner informs the registrar in writing of the finding and other particulars, and in case of a dead body being found exposed, he must give notice to the registrar. By the 18 & 19 Vict. c. 108, he must also give previous notice to the secretary of state, of inquests on deaths from accidents in coal mines. The coroner has no authority to take an inquisition of death, except upon view of the body by himself and the jury; and if he does so, the inquisition is wholly void. (Rex *v.* Ferrand, 3 Barn. and Ald. 'Reports,' 260.) If a body liable to an inquest has been buried before the coroner has notice of the circumstances of the death, he has authority to cause it to be disinterred for the purpose of holding the inquest, provided he does so within a reasonable time. By the stat. 7 Geo. IV. c. 64, § 4, which repeals an ancient enactment on this subject, it is provided that "every coroner, upon any inquisition before him taken, whereby any person shall be indicted for manslaughter or murder, or as an accessary to murder before the fact, shall put in writing the evidence given to the jury before him, or as much thereof as shall be material; and shall have authority to bind by recognisance all such persons as know or declare anything material touching the said manslaughter or murder, or the said offence of being accessary to murder, to appear at the next court of oyer and terminer, or gaol delivery, or superior criminal court of a county palatine, or great sessions, at which the trial is to be, then and there to prosecute or give evidence against the party charged; and every such coroner shall certify and subscribe the same evidence, and all such recognisances, and also the inquisition before him taken, and shall deliver the same to the proper officer of the court in which the trial is to be, before or at the opening of the court." And by a subsequent section, authority is given to the court to which the inquisition ought to be delivered to examine in a summary manner into any offence committed by the coroner against the act, and to punish him by fine. The coroner's inquisition may be removed into the Court of Queen's Bench, and the facts found may be traversed by the personal representative of the deceased; or the court may make it for any apparent defect.

For every inquisition taken in any place contributing to the county rates, the coroner is entitled to a fee of 20*s.*, under the 25 George II. c. 29, and by the 1 Vict. c. 68, to an addition of 6*s.* 8*d.* He is also entitled to 9*d.* for every mile he is obliged to travel from his usual place of abode for the purpose of taking it, to be paid by order of sessions out of the county rates; and by the 7 & 8 Vict. c. 92, coroners may be paid travelling expenses, although in the exercise of their discretion they may have deemed it unnecessary to hold an inquest. By the act 6 & 7 Will. IV. c. 89, the coroner is empowered to order the attendance of legally-qualified medical practitioners upon an inquisition of death, and to direct the performance of a *post mortem* examination; and if the majority of the jury are dissatisfied with the first examination, they may call upon the coroner to summon a second medical witness, to perform a *post mortem* examination, whether it has been performed before or not. The same statute also, as amended by the 1 Vict. c. 68, requires the coroner to pay a fee of one guinea to such witness, if he has not performed a *post mortem* examination, and of two guineas if he has performed such examination. Medical practitioners are also liable to a penalty of 5*l.* if they neglect to attend.

The act 1 Vict. c. 68, authorises the justices of the peace in England and Wales, at their quarter-sessions, and the town councils of every borough which has a coroner's court, at their quarterly meetings, to make a schedule of the fees, allowances, and disbursements which the coroner is allowed to pay (except the fees payable to medical witnesses, under 6 & 7 Will. IV. c. 89), on holding any inquest. This schedule regulates for each county or division of a county the expenses to be paid to the constable for summoning witnesses, &c. There is usually a small sum allowed to each juryman, generally 1*s.* 6*d.* in counties and 1*s.* in boroughs.

The coroner has also occasionally to exercise a ministerial office, where the sheriff is incapable of acting. Thus where an exception is taken to the sheriff on the ground of partiality or interest, the king's writs are directed to the coroners. This incident to the office of coroners points distinctly to their ancient character as ministerial officers of the crown. When acting for the sheriff the coroner is, by the 7 & 8 Vict., entitled to the same fees as the sheriff.

By the Municipal Reform Act, 5 & 6 Will. IV. c. 76, § 62, the council of every borough, to which a separate court of quarter sessions has been granted, is empowered to appoint a fit person, not being an alderman or councillor, to be coroner of the borough, who is to hold his office during good behaviour. The fees and general duties of borough coroners are the same as those of county coroners; but the former are required by the statute to make an annual return to the secretary of state of all inquests of death taken by them. [DEODAND.] (See Hawkins's 'Pleas of the Crown,' book ii. cap. 9; Burn's 'Justice,' tit. 'Coroner;' and Jervis's 'Practical Treatise on the Office and Duties of Coroners.')

CORONET, an inferior kind of crown worn by the nobility. Of coronets worn by foreign nobility much may be seen in Selden's 'Titles of Honour,' and in Montfaucon; see also Gough's 'Sepulchral Monuments,' vol. i. pp. 133, 134. No coronets belonging to peers can be found in England earlier than the time of Henry III. The coronet seems at first to have been the distinctive mark of an earl. William de Valence, earl of Pembroke, who died in 1304, and is buried in Westminster Abbey, has only a plain fillet. Aymer de Valence, however, acknowledged by his treasurer the receipt of a coronet at his creation of earl in 1319. (See Gough, 'Sep. Mon.,' i. p. 86, from Selden's 'Tit. of Hon.') John of Eltham, second son of Edward III., who died in 1334, and is also buried in Westminster Abbey, has a coronet on which are leaves; it is the most ancient of the sort we meet with. Edward the Black Prince, who is buried at Canterbury, has his helmet adorned with a coronet of oak-leaves, formerly enriched with paste, or false stones, of which the collets only remain. (Ibid. i. 136.)

Of the coronets of the British nobility, as at present worn, all surround caps of crimson velvet turned up with ermine. That of a duke is a circle of gold, richly chased, having on the edge eight strawberry leaves of equal height: that of a marquess, a circle set round with four strawberry leaves and as many pearls on pyramidal points of equal height alternately: the earl's coronet has eight pyramidal points (five only being seen at a time), with as many pearls on the tops, placed alternately with as many strawberry leaves, lower than the pearls. The viscount has only pearls, without any limited number, placed on the circle itself all round. A baron has only six pearls set at equal distances. Viscounts and barons had no coronets allowed them till after Queen Elizabeth's reign; the former had them granted by king James I., the latter by a grant from Charles II. in the thirteenth year of his reign. In Sir Symonds D'Ewes's letter, giving an account of the coronation of king Charles I., it is expressly said that when the higher order of the peerage put on their coronets, the barons sat bare.

The coronet of the kings of arms is a plain circle of gold, bearing sixteen leaves, eight of which are higher than the others: and on the band, the motto "Miserere mei, Deus."

CORPORAL (in the French service *caporal*), a non-commissioned officer in a battalion of infantry. The word is derived from the Italian *capo*, signifying a head; and the title denotes that the person who bore it was the chief of a small squadron or party. During the reigns of Mary and Elizabeth, the corporal was a kind of brigade-major; he superintended the marches of the companies, and commanded the troops who were sent out on skirmishing parties. But at present he is immediately under the serjeant; he commands small guards, and places and relieves the sentries. He falls into the ranks and does the same duty as a private soldier, but his pay is rather higher.

Lance-corporal, originally *lance-spasata*, denoting a broken or spent lance, was a term applied to a cavalry soldier who had broken his lance or lost his horse in action, and was subsequently retained as a volunteer in the infantry till he could be remounted. He is now merely a soldier who does the duty of a corporal, but without the pay, previously to obtaining the full appointment to that grade.

The rank of corporal is indicated by two stripes on the arm, that of lance-corporal by only one.

CORPORATION. In the progress of European society the want was early felt, of some means by which a permanent existence might be given to undertakings, arts and crafts, to religious doctrines, systems, or mysteries; to sanitary or other eleemosynary foundations, and other matters of permanent interest and importance to each succeeding generation of men. Thus, if a trade or handicraft had reached to excellence, it became desirable to provide for keeping together its professors, for the conservation of its secrets, and for imparting them to a chosen few, who should in their turn perform the same duty to others, thus, as it were, perpetually keeping the lamp trimmed and burning. In this mode arose the idea of incorporation, or of establishing a fictitious person—an invisible entity—which should have powers of holding property, and of doing various acts like a human being, but having besides a perpetual duration and identity. Another instance may be stated: if it was desired to perpetuate a system of augury or divination, intended to aid in the government of future generations, the idea of incorporation was resorted to; in other words, a body of persons was constituted with powers and under obligations to provide in certain appointed ways and modes for the maintenance of the body, by the election of a new member whenever a vacancy in the existing members should occur, constituted also, with certain fixed rules, as that the concerns of the body should be determined by the majority of voices; and this being done, property was vested in the abstract person or continuous entity, from the proceeds of which the expenses of the collective body were provided for. By this invention there was always in being a holder of the property; always a succession of members to manage and apply it. The subtle idea of, in this way, combining, in a metaphysical creation, the legal characters of the finite being with the essentials of infinity, is undoubtedly attributable to the Romans of the period which is usually assigned to the reign of Numa Pompilius. As society developed, the idea of establishing a continuous identity was applied to a variety of purposes: it furnished municipalities with a form of government which never wore out; charitable foundations and trusts were secured to the use and benefit of the objects of them, as long as such objects should continue to be found; education was provided for, and learning and religion kept alive through times through which perhaps no other means would have sufficed to carry them. It has been, however, in the shape of municipal incorporation that the idea has perhaps worked most conspicuously for the benefit of mankind as regards times past; the municipalities having no doubt been of the greatest service in preserving liberty, in cherishing trade and manufactures, and diffusing generally a spirit of liberty, self-reliance, and improvement among the people of Europe in the early and middle ages of modern times. That the Roman municipal system was never quite extinct in Europe is the opinion of the most distinguished scholars, jurists, and historians—Niebuhr, Savigny, Raynouard, Palgrave, Hallam, and various Italian authorities. In this country it is probable that the various municipal and other corporations, which are said in law to be corporations by prescription—that is having an origin some time before the reign of Richard I.—are traceable to the times of the Romans: thus London, York, Colchester, and many other cities and towns known to have been places of Roman residence, have ever been considered to have been incorporated at some very early period; and the same is the case of the stallingers of Sunderland, the dredgers of Whitstable, the free fishermen of Faversham, &c. (For Corporations among the Romans, see Heineccius, 'De Collegiis et Corporibus Opificum,' Opera, tom. ii., p. 368; the Italians 'Historiæ Patriæ Monumenta,' Turin 1836; and 'Muratori Antiquit.' iv. pp. 5, 159; German and Spanish Corporations, Robertson's Works, vol. iii., pp. 227-229; French, Raynouard, de Tocqueville 'France before Revolution of 1789,' p. 76, and 428 n.; English, Merewether and Stephens 'History,' 3 vols.; Hallam, 'Supplementary Notes to History of Middle Ages.') Some Piedmontese charters of incorporation date as far back as A.D. 707; and these are believed to be the oldest authentic charters in existence.

A charter, proceeding from the sovereign, was for long, the only known mode of creating a corporate body either in this or any other country of Europe. This consisted of a letter or rescript of the sovereign sealed with his royal seal, in which he called into a corporate existence the person or entity whom it was intended to establish, endowed it with a right, and fixed upon it the obligation of keeping up a perpetual succession of the members, gave it a name in which it was to sue and be sued, to hold land and other property, and to do all other acts, &c. It was also enabled to have a common seal, to be the emblem of its will; its concerns being in general managed by the voice of the majority of its members, who in all things bound the minority, and who signified the resolutions of the corporation, authenticated its contracts, &c., executed its deeds, &c., by affixing thereto the common seal. In this country the mode of incorporation by charter is at present but seldom resorted to, having been nearly superseded by the more modern device—dating only from the Revolution—of an act of parliament for each case, containing such regulations, imposing such restrictions, and giving such powers, as it is competent to parliament to appoint. Such is the nature and constitution of corporations, bodies politic, bodies corporate (as they are indifferently called), consisting of many members, or "aggregate of many," in the technical language of the law.

There is besides this another class of corporations called corporations sole, to which belong the king or queen regnant in his or her public capacity, every archbishop or bishop, every parson of a parish, &c.; but by much the more important class, at the present day, is the former, and to that therefore we shall chiefly direct our reader's attention in the remaining part of this article.

Corporations aggregate may be treated under the heads of Corporations in general (which would include ecclesiastical, sanitary, eleemosynary, educational, and other corporate bodies); municipal corporations; trading corporations. (See Kerr's Blackst. 'Comment.,' vol. i. cap. xviii.) The life and functions of *every* corporation aggregate are the creation of its charter or constituting statute (as the case may be); they do not exist for any other than the purpose therein specified; for any other purpose the members are merely an unorganised number of persons, not bound by the numerical majority, not a body, not a partnership, wholly unrecognised as endowed with aggregate capacity or collective powers. Hence it is idle to contend, as is sometimes done, that the acts and deeds of corporations are to be received and treated like the acts of natural persons or individuals; for corporations are artificial persons, and there is an essential difference between their acts and those of individuals. An individual may do what he likes with his own; he may bind himself by deed disposing of his property, however capriciously, without equivalent passing to him, without the law of England investing the courts with any power of interference, provided no fraud has been practised on him. But a corporation is fettered in its volition by the terms of its constitution: to them its course must be conformed. Any act done, or agreed to be done, either in violation of those terms or for purposes not comprised within those terms fairly construed, is illegal at law and will be restrained in equity,—such illegality forming a defence at law for the corporation when sued for the non-performance of its undertaking to do the act, or the ground of an injunction in equity to prevent the corporation from applying its funds for the purposes so unauthorised or prohibited.

Among the powers and capacities which are common to all corporations aggregate, are, those of having a corporate name; of suing and being sued in that name; of having a common seal, and doing all acts, executing all contracts, deeds, grants, orders, notices, and generally all formal documents by and under that common seal; to take goods as long as that body endures, and as incident thereto to lease, mortgage, and charge the same; to make and establish what are called "bye laws" (in the language of the law), being regulations for the management of the concerns of the corporation, the government of its members, and in many cases of persons other than its members, who may come within its sphere of action [BY-LAW]: these, when once duly passed, can only be abrogated by a counter vote of a majority of the body duly assembled, or by a judgment of a court of justice overturning them as being contrary to some principle of the general law of England. All the acts of the body are determined by the vote of the majority of the members duly in corporate meeting assembled.

Whilst the majority is acting for the objects and within the scope of the constitution of the body, they are never liable at common law, in their own persons, for the consequences of what they determine to do as a corporation; such act is the act of the corporation, and if any one is aggrieved by that act, the corporation is the proper person to be sued, not the aggregate or the majority, or any other part of the members; and if judgment goes against the corporation it pays the damages or the penalty out of its corporate funds. If, however, the majority take upon them to use the corporation powers and apply its funds to other purposes than those for which the body politic was called into existence, there are various cases in which the individual members of the majority may be made liable to answer, with their own property, the injury that their conduct may have done to others, whether strangers or members of the same body. There are means also by which projected applications of the powers and funds of the corporation, to purposes and objects for which the body was not constituted, and the funds were not devoted, will be prevented in the courts of equity.

As a corporate body is thus incapable of doing anything which is beyond the objects for which it was established (for it has not been given a perpetual existence and endowed with powers except for the accomplishment of the particular ends for which it was created), to do anything not comprised in them is *ultra vires*, and the attempt to effect it is void. So, as a matter of course, the body cannot put a period, by any act of its own simply, to its own corporate existence; although, in cases where the corporation has been established by a charter, the majority, with the consent of the crown, may resign or surrender the charter, which being accepted, the corporation is extinct. A corporation may also pass out of existence by reason of all the members dying out, care not having been taken to keep up the number of the members, by fresh elections, as vacancies occurred. Or a corporation may be dissolved or abolished by statute, though this has only been done, against the will of the bodies concerned, in the case of the Knights Templars, and of the convents and priories in the reign of Henry VIII. But the crown cannot, of its own will, abolish a corporation.

Corporations for ecclesiastical, eleemosynary, and educational purposes differ chiefly from municipal and trading corporations in this,—that they have appointed to them by the terms of their foundations *visitors*, whose duty and right it is to see that these bodies perform the duties with which their institutions are charged, and who, for that purpose, are armed with unique summary powers, for from their decisions there is no appeal. It is to this class of corporations chiefly (though not exclusively) that the statutes of Mortmain apply, restraining corporations from holding land without a licence from the crown, and the statutes of Charitable Uses, preventing corporations from holding land devised or granted to them for charitable purposes, except the grantor, &c., have first complied with certain requirements. [MORTMAIN.]

Municipal corporations are those by and under which the cities, and nearly all the principal towns, of this country are governed. Having originated, some by prescription and others by charter, and having therefore constitutions originally of very great variety, as well as a number of customs prevalent within them, chiefly in restraint of trade, they were all reduced to a common model by a statute of William IV., which, with some additions and modifications from subsequent statutes, has remained the governing statute since 1835. All the above-mentioned customs of trading were at the same time abolished, the statute applying to the municipal corporations of England and Wales except that of London, the customs of which have repeatedly been confirmed by parliament; and as yet (1859) London is left nearly untouched by municipal reform.

Trading Corporations.—A partnership is a company of persons associated together for the purpose of making profits by trade, each of the partners being entitled to such a share of the net profits, at the end of the year, as may be agreed upon and settled by the deed or other instrument, or by the terms of the partnership, and each bearing losses, where any occur, and being liable to the whole extent of his fortune. A trading corporation, however, is an incorporated association, having a joint or common stock of money, mostly divided into equal shares, the possession (by purchase for the most part) of one or more of which constitutes membership: the business is conducted for the common profits, the net returns of it being thrown into a common fund, out of which a rateable proportion is divided periodically, according to his number of shares, to each member, such proportion being called the dividend. Thus, then, the business is worked, in the legal sense, by the corporation, for its profits in the first instance; all outgoings are paid and all contracts made by the corporation, which is responsible, in its common stock, for all claims, whether in the nature of debts, or for compensation in damages for negligence or misfeasance, and the dividends are made out of the surplus remaining of the profit fund after defraying these and all other charges. In these bodies, like as in other corporations, no member has any individual right to any portion of the property, real or personal, of the company except so far as a declaration of dividend entitles him to his proper portion of the profits, on any periodical division; but unlike what takes place in common law corporations, the members of joint stock trading corporations, are, by statute, liable personally to the debts of the corporation after the common fund has been exhausted, and even those who are no longer members, may, in certain cases, remain liable for a period of three years after they have ceased to hold shares. Most classes of trading corporations may be dissolved by virtue of statutory enactments, applying to those classes, by means of what is called "winding up," under which system an account is taken of their debts, liabilities, and assets, and if necessary the members are called upon to contribute rateably, according to their shares, such sums as in the aggregate suffice to balance the accounts of the company. (See Kerr's Blackstone's 'Comm.' vol i. chap. 18.) The modern trading corporations bear little or no resemblance to the incorporated trades or guilds of the middle ages, which were associations for the teaching and managing, each of its particular handicraft, and for eleemosynary purposes, in regard to its members, who might fall into decay. They were not established with any view to traffic or the making of profits.

For incorporated companies trading as bankers, see Grant on 'Banking', and the article Bank, Banker, Banking.

For general information on corporations, see Grant's 'Law of Corporations,' where particulars are stated of the law respecting the universities and their colleges; grammar schools; hospitals; dean and chapters; guardians of the poor; bishops, parsons; and generally respecting all descriptions of corporate bodies known in this country.

CORPORATIONS (MUNICIPAL) OF IRELAND. The present constitution of the boroughs of Ireland, will be treated under Municipal Corporations. The following is merely a historical notice of some of the peculiarities no longer existing, which marked the Irish corporations.

The whole system of boroughs, which holds so conspicuous and important a place in the history of the political and general civilisation of the British islands, is, in nature as well as name, of purely Teutonic original: that particular species of organisation having ever been found repugnant to the habits and spirit of the Celtic nations in their independent state. Thus, in Great Britain itself, its local limits advanced with the growth and extension of the Germanic colonies both north and south of the Tweed; and in Ireland we find that the native race were strangers to it until the settlement on their eastern and southern coasts, about the 9th century, of some of those Danish, North-man, or, as they were called in Ireland, Ost-man (East man) bands, in that great æra of the permanent migrations of those formidable sea-rovers. Of these maritime settlements, five, namely, Dublin, Wexford, Waterford, Cork, and Limerick, appear as places of note at the commencement of the Anglo-Norman conquests in the island, and as possessing that municipal organisation which constantly attended all the branches of the Teutonic race. The Ost-man colonists of Ireland, too, though for a considerable time after their first settlement they adhered to their ancient paganism, had at the period in question, owing undoubtedly to the amicable relations which had arisen between them and the Irish population, and to the exertions of the Irish clergy, been long in the profession of Christianity; so that, it should seem, the first Anglo-Norman invaders might have recognised in them some degree of national affinity. But being ignorant and brutal, though subtle and daring adventurers, their thirst for plunder and for territorial acquisition would not permit them, in their career of murderous rapine, to make any distinction in treatment between the Scandinavian and the Celtic blood, between the Ost-man and the Irishman.

This unsparing temper of the early private invaders perfectly coincided with the policy of the English crown; and so soon as Henry II. had found leisure to take the business of the invasion into his own hands, one of his principal measures for securing the footing of his government on the Irish soil was the colonisation of the Ost-man ports with English or Anglo-Norman settlers. Thus the Ost-men of Dublin were thrust without the walls of their city to inhabit the suburbs thence called Ost-man town, and still, by corruption, Oxmantown, giving place to a band of mercantile settlers from Bristol, who became the English king's "burgesses" of Dublin, with a charter of liberties modelled exactly upon that of Bristol. In like manner, during the various fluctuations of the territorial conquest, down to its completion at the close of the reign of Elizabeth, every permanent extension of the English frontier extended the English organisation of the territory, of which the establishment of fortified towns, with inhabitants municipally organised and trained to arms, was a constant and a prominent feature.

The municipal commissioners of 1833 could not help observing the "marked distinction in the language of their charters, as to the constitutions of the municipal corporations in Ireland, according to the dates of those instruments," that is, according as they were granted before or after the commencement of the reign of James I. This was precisely the period when the crown was most actively exerting itself to secure the power of moulding the borough constitutions at its pleasure; and in the middle of James's reign was given the notable judicial decision in favour of the prerogative of establishing close boroughs by charter, upon which the crown ever afterwards acted. Far, however, as the exercise of this power was carried in England, yet, in the hands of the Stuarts at least, it failed of the complete attainment of its object. But in Ireland, which presented a much clearer field for its exertion, it was used both lavishly and effectually, not only in establishing new boroughs, but in reframing the constitutions of the old ones. In the "plantation of Ulster," as the settling of British inhabitants upon the lately forfeited lands there was then denominated, by charters granted by James to various "undertakers" of the plantation, a number of incorporations were made beforehand, on the new and approved plan of towns "to be built" on the respective lands. Another and very similar mode of making boroughs in Ireland at this period was the incorporating of some village already existing, at the same time placing its corporation under the absolute control of the lord of the manor existing previously or newly erected. The whole number of boroughs thus created by James I. and his two immediate successors, a large proportion of which were originally of the class just described, though some of them have since risen to importance, was 61, and the number of the older boroughs was 45; there were also 11 other places which sent representatives to the Irish parliament, though no charters were in existence but which derived their right from usage.

Each of the 106 corporations referred to above, sent two members to the Irish House of Commons, and many of those created by James I. and his two successors served scarcely any other purpose from the beginning, their incorporation having been little more than a cover for the nomination of the two members by the landed proprietor. Many had consequently fallen into virtual disuse long before the legislative union with England.

The mode of incorporation adopted by the crown in erecting the modern boroughs, presents little more than a parallel to the course it was pursuing in England; but in order to explain how it was that the subversion which it effected in the *ancient* borough constitutions of Ireland was so much more rapid and more complete than in those of England, we must advert to some very remarkable features in the politico-religious history of Ireland.

In the very first establishment of boroughs in that country, the Anglo-Norman crown had found itself under an absolute necessity of placing the municipalities on the footing of the most favoured class of boroughs in England: the security of the English power upon the Irish soil required that the incorporated burgesses should be strong and prompt for defensive warfare; and, to be so, it was essential that they should be free. Not only therefore were the municipal and the parliamentary franchise enjoyed by the inhabitant householders at large, but their common exemption from burdensome duties and services, and from feudal jurisdictions, was rendered more effective than in England itself; and such, on the whole, did the civil condition of the Anglo-Irish boroughs continue to be until the completion of the territorial conquest. This completion, while it relieved the ancient boroughs from the danger of external attack from the unsubdued native Irish population, rendered their internal freedom more liable to attack from the English crown, at length relieved from the risk and embarrassment of the old contest with "the Irish enemy." Another remarkable circumstance appeared just at the same period, which, while it commenced an entirely new era in Anglo-Irish history, placed in the hands of the English government a weapon of sweeping efficiency for the prosecution in Ireland of its new policy towards ancient boroughs in general. When Henry VIII. had abolished, to his own advantage, the papal supremacy in England, the new religious reformation obtained only a partial reception in Ireland. In the reign of Elizabeth two statutes were passed relating to the crown's religious supremacy and to the uniformity of common prayer; but her government was too discreet to enforce either of them, except as to the clergy and the leading officers acting in civil capacities under the government. But James I. sent presidents or military governors through the Irish provinces for the immediate enforcement of the statutes in question, especially in the corporate towns. The leading municipal officers were ejected, others, of known pliancy, were substituted in their places; and these persons readily resigned the rights and liberties of their towns into the king's hands, and took out new charters of incorporation. And here it was that the leading object of the crown was accomplished. To the several ancient boroughs new charters were soon issued, so framed as to leave but a very small share of municipal power to the great body of the inhabitants. In these charters individuals were expressly nominated to fill the offices of mayor, sheriff, recorder, &c.: the members of the governing council of the corporations were in most instances nominated in like manner, with exclusive power to appoint their successors; so that the inhabitants at large were almost wholly deprived of that share in their local government which, under the original constitutions of these boroughs, they had enjoyed for upwards of four centuries.

The system of exclusion was closely pursued by the persons thus newly placed in corporate authority, who, by this means, gradually severed their interests from those of the inhabitants at large: still they were unable wholly to extinguish the municipal rights of the ancient class of freemen, who though excluded by test-oaths from the higher corporate offices, continued pretty numerous until the year 1654, when the army of the Commonwealth obtained possession of all such towns. No sooner was Charles II. restored than the Lords Justices of Ireland issued a proclamation confirming to every one holding by grant or contract with "the late usurped powers," all their lands and possessions, as well in towns as elsewhere, during a given period. Under the authority of this proclamation, when the Irish legislature was called together for the general arrangement of landed property, and other public interests, which had been completely subverted by so many years of civil war, the Commonwealth soldiery, who, under Cromwell, had possessed themselves of the walled towns, were able to return an overwhelming majority of members to that parliament which passed the Acts of Settlement and Explanation. The permanence of their interest was thus provided for; and the estates, rights, and liberties of those corporate establishments were vested in a body of men but recently settled in the kingdom. The unjust exclusion consequently maintained, became, in the course of the same reign, a subject of inquiry with the Irish government; but, wavering as that government has so often been between justice and expediency, it procured no effectual change in that system, the evils of which it seemed to deplore.

One measure, however, was taken at this period, the tendency of which was to mitigate in some degree the spirit of absolute exclusion prevailing in the Irish municipalities. The Act of Explanation empowered the Lord Lieutenant and Council, within seven years, to make rules, orders, and directions, for the better regulation of all cities, walled towns, and corporations. By virtue of this power, the Lord Lieutenant and Council, in 1672, issued what are called the "New Rules," which ordained that thenceforward the elections of persons to serve the offices of mayor, sheriff, recorder, or town-clerk of Dublin, Limerick, Galway, and the several other towns therein mentioned, should be subject to the approbation of the Lord Lieutenant and Council; and that no person should be capable of acting as mayor, recorder, sheriff, treasurer, alderman, town-clerk, common-councilman, or master or warden, until he should have taken the oath of supremacy, except such only with whose taking that oath the Lord Lieutenant should think fit, by name and in writing, to dispense. But that part of these New Rules which tended to restore the ancient basis of the municipal franchise, was a provision that all "foreigners, strangers, and aliens, being merchants, or skilled in any mystery, craft, or trade," then or thereafter residing and inhabiting within those cities or towns, should, on paying down a fine to the mayor and common council, or other persons authorised to admit freemen, be admitted to the freedom of such city or town respectively, and if they desired it, into any guild, brotherhood, &c., therein; that any person refusing to admit them so applying for their freedom should, upon due proof before the Lord Lieutenant and Council, be for ever deprived of the freedom of such city or town; and further, that on such refusal of admission by the corporate authorities, such person so applying should, on tendering twenty shillings, and taking the oath of allegiance before any justice of peace in the adjoining county, be therefore deemed, to all intents and purposes, a freeman of such corporation, guild, &c. Thus, in spite of the exclusive system then in operation, every resident trader in the corporate towns of Ireland was enabled, under these rules and orders, to become a freeman; though still, except by special dispensation, he could not fill the higher municipal offices, unless by taking the oath of supremacy and giving the other tests then required.

But after the Revolution of 1688, the spirit and intention of this portion of these rules were wholly disregarded. Owing, indeed, in some degree to James II.'s unsuccessful attempts against his opponents in the corporate towns of Ireland, the system of absolute exclusion pursued in the early part of his brother's reign was revived with aggravated rigour; and under such circumstances little was to be expected from seeking the benefit of the rules and orders, or bringing in any other mode the rights of the excluded before such tribunals as then existed. From these causes, and from a sort of inviolability or sacredness of character which was thrown about corporate establishments in Ireland from the reign of William III. to the passing of the Irish Municipal Corporations Act in 1840, by which a number of them were disincorporated, and the remainder, in their constitution, were assimilated to the English boroughs as regulated by the Municipal Corporations Act, England (1 Vict. c. 78, 1837), by which all religious distinctions as affecting the rights of the inhabitants were wholly abolished, the inhabitants at large of municipal towns remained wholly unconnected in interests or feelings with the few individuals monopolising all corporate authority.

CORPULENCE. [Obesity.]

CORPUS JURIS CIVILIS. The term corpus juris (literally a body of law) which so far back as the year 1262, was specially applied to the several compilations made by Justinian (Sarti 'de Claris Archigymn,' t. i. pt. ii. p. 214), was not then used for the first time, for Livy (iii. 34), in narrating the history of the introduction of the decemviral code, and the reception it met with at Rome, states that the common impression was that two more laws were wanted to complete the work, for if they were added "absolvi posse velut corpus omnis Romani juris," whilst Justinian himself uses the term in the sense of the collection of Roman law then in being (C. 5. 13 pr.) But there are now two principal collections to which that appellation is given, the Corpus Juris Civilis and the Corpus Juris Canonici. [Canon Law.] The term Corpus Juris Civilis designates the book in which the different parts of the legislation of the Emperor Justinian are collected, and which, considered as one whole, contains the main body of the Civil or Roman law. According to this definition, the Corpus Juris Civilis consists of the compilations of the codex, pandects or digests, institutes, and novels, which were made under the direction of the emperor Justinian.

Justinian himself, regarding each part of his legislation as a separate collection only made for the purpose of completing former compilations, never thought of giving a common title to them all. Each part had its separate and appropriate name; for instance, the codex was so called because it was the book in which the Roman emperors' constitutions were collected; the institutes were so called because they contained the first principles and rules of the law; the digest or pandects because they were the collection of the digested decisions and opinions of the old lawyers, forming a common receptacle of legal learning (C. I. 17, 3, 1); and the novels because they were new constitutions (novellæ constitutiones), published by imperial authority after the appearance of the former works, namely, between the years A.D. 535 and 559. In the middle ages, when the study of the Roman law began to flourish in the universities of Italy, the jurists were led to consider Justinian's separate collections as one entire legislation, to which a general title would be appropriate. Savigny, in his history of the Roman law in the middle ages, asserts that the term Corpus Juris Civilis was used in the 12th century. However, Russardus, professor in Bourges (which, in the 16th century, was one of the most celebrated French universities for jurisprudence), who first edited the collections of Justinian under a common title, at Lyon, in the year 1561, chose only the term Jus Civile for that purpose; and Dionysius Gothofredus, likewise a French jurist of Paris, is commonly considered as the first who, in his edition in the year 1583, at Lyon, adopted the term Corpus Juris Civilis as a general title for the collections of Justinian, for before this time each of the three volumes into which the glossers divided the collection, was known by a particular title; the first volume being called 'Digestum Vetus,' comprising the first twenty-three books and the first two titles of the twenty-fourth book; the second volume, 'Infortiatum,' running from the third title of the twenty-fourth book to the eighty-second paragraph of the second title of the thirty-fifth book; and the third volume 'Digestum Novum,' containing the remainder of the work. (See in 'Heynii Opuscula Academica,' vol. ii. p. 315, some remarks on this division.) From the time of Gothofredus his title has always been in use.

The Corpus Juris Civilis, as it is now composed, contains: 1. The Collections of the Emperor Justinian, namely, the Institutes, in 4 books; the Pandects or Digests, in 50 books; the Codex, in 12 books, together with the Authenticæ, a name given, not by Justinian, but by the Glossers (professors of law, who in the 12th and 13th centuries taught the Roman law and explained the text of the Corpus Juris in the universities of Italy, especially Bologna) in order to distinguish the collection made by them and appended to the Corpus Juris from the Epitome Novellarum made by Julianus, A.D. 570; the number of these Novellæ Constitutiones is 168. 2. An arbitrary appendix, joined to the Corpus Juris by different editors since the time of Russardus, namely, *a.* several Constitutions of the Emperor Justinian and his two successors Justinian II. and Tiberius II., called Justinian's 13 edicts, which were first received into the Corpus Juris by Russardus; *b.* several other Constitutions of the same three emperors, which were first added by Contius, in his edition of 1571; *c.* 113 Constitutions of the Emperor Leo, the philosopher, given by him for the purpose of amending and correcting Justinian's legislation, together with a Constitution of the Emperor Zeno, likewise first added by Contius in his edition; *d.* a series of Constitutions of the successors of the Emperor Justinian from the 7th to the 14th century, first added to the Corpus Juris in the edition of Charondas of 1575; *e.* a series of 84 (or 85 according to the older division) ecclesiastical Canons, called Canones Sanctorum et Venerandorum Apostolorum, first added to the Corpus Juris by Gregorius Haloander about A.D. 530. According to the descriptive title by which they are headed they are to be ascribed to Clement, the first bishop of Rome, but their origin and history are involved in so much doubt that many writers have not hesitated to pronounce them to be apocryphal and devoid of authority (Dupin, 'Bibliothéque Ecclesiastique,' t. 1, p. 135); probably they are a private collection of decrees of councils and synods existing prior to the synod of Nicæa, A.D. 325; *f.* the Libri Feudorum, that is, the books which contain the usages and customs of the feudal system, and which were joined to the Corpus Juris by the Glossers; *g.* several Constitutions of the Emperor Frederic II.; *h.* a short book in ten titles, called 'Extravagantes, or Undecima Collatio,' containing some Constitutions of the Emperor Henry VII., A.D. 1312; *i*, and last of all, the Liber de pace Constantiæ, or the Treaty drawn up, A.D. 1190, between Frederick I, and the Lombard States, by which the freedom of twenty-four Lombard cities was granted. In several editions we find other appendages besides those here noticed.

The manuscripts of the Corpus Juris Civilis are numerous, but nearly all of them contain only a part of Justinian's legislation: manuscripts containing the whole body of law are very rare. The best MS. of the latter is at Copenhagen. Of MSS. before the time of the Glossers we have only one of the Pandects, the celebrated Florentine manuscript, which was first at Pisa, but was brought to Florence in 1411, after the capture of Pisa, A.D. 1406; it probably belongs to the 6th or 7th century, and some even suppose that it may be the original copy of the Pandects which was sent by Justinian to the Western Empire. Whatever its early history may be, whether, as Odofredus says, it was brought to Pisa from Constantinople, or as the old story, constantly repeated and supported by Brencman among others, has it, that it was given to the Pisans by Lothario II., after the capture of Amalfi, A.D. 1133, its importance consists in the claim set up for it as being the sole authentic source from which the text of all other MSS. has been taken; a claim as earnestly opposed as it has been hotly contended for, and only to be settled, if it be possible, *tantas componere lites*, by the conjecture that there was another manuscript coeval with or prior to the Florentine text and accessible to the Glossators, and that each of these was copied from one and the same original. The other manuscripts are of the 12th 13th, and 14th centuries, and contain the *versio vulgata*, or text as settled by the Glossators according to older manuscripts. In Munich and Paris there are valuable manuscripts of the *versio vulgata* of the Codex. As to the manuscripts, see Beck, 'Indicis Codicum et Editionum Juris Justinianei Prodromus,' Lips. 1823. Of the manuscripts in England, there is a valuable notice in the 5th vol. of the 'German Magazine of Historical Jurisprudence.'

There are numerous editions of the 'Corpus Juris:' it was printed very soon after the invention of the art, but at first only separate parts were published. The oldest edition that we know of is that of the Institutes, by Peter Schœffer, in Mentz, of the year 1468. There is a copy of this edition on vellum in the King's Library, British Museum. It has a small illumination of a presumed portrait of Justinian in the title-page. The larger capital letters throughout the books are illuminated, and some of them with gold. The last edition of importance is that of Schrader (Berlin, 1832), who formed the design of preparing an accurate and trustworthy edition of the 'Corpus Juris Civilis.' Till the year 1476 all the parts of the 'Corpus' were printed separately. The first edition, which contained the whole, is that by Honate, at Milan, of the years 1482 and 1483, but still not under a general title, which, as already mentioned, was first used by Russardus. Till the year 1518 all the editions were printed with the glosses, but after that date the glosses were commonly omitted. The last edition with glosses is of the year 1627. For a complete list of the editions, see Beck's 'Index.' Probably there are no editions that have been so generally received and have met with such favour as those of the celebrated Denys Godefroi; of these, the first, a quarto, appeared in 1583; the second, 2 vols. folio (a revised copy of the first), in 1590; the third, 4 vols. folio, in 1602; and the fourth, 2 vols. folio, in 1607; all of them being published at Lyon. These were followed in the year 1624 by an edition more complete than any that had preceded it, published at Geneva by his son James. In 1663 Simon Van Leeuween produced a folio edition at Amsterdam, in which not only the notes of Godefroi were given, but those of several other distinguished commentators; and in the same year a copy of Godefroi's first edition was published at Frankfort. The book, though extremely scarce, has very little to recommend it to the student. J. L. G. Beck, in 1825, published a very useful and carefully edited copy of the 'Corpus Juris' in two quarto volumes.

CORPUSCULAR THEORY. [MOLECULAR THEORY.]

CORRECTION, HOUSES OF. [REFORMATORIES.]

CORRELATION OF PHYSICAL FORCES. [FORCE.]

CORRIDOR, from the Italian *coridore*, signifies a gallery or passage-way leading to apartments independent of each other. In all large buildings containing numerous apartments corridors are necessary, either closed or open. The corridor round the great cortile or open court of the Cancellaria at Rome, designed by Bramante, consists of an open gallery supported by columns.

CORROSIVE SUBLIMATE. [MERCURY, *Bichloride of.*]

CORRUGATION. A very simple but effective mode has been adopted during the last few years, of imparting additional strength to sheet metal. This consists merely in *corrugating* it; that is, bending it into a series of opposite curves, convex and concave alternately. The usual mode of producing this result is by passing the sheets between two rollers corrugated on their surfaces, rings of depression alternating with rings of protrusion, and the protuberances of one roller corresponding with, and working into, the depressions of another. If the two rollers work nearly in contact, a sheet of metal passed between them is forced to take a corrugated form; and if the rollers be powerful while the metal is thin, this might be done when cold; otherwise a heating of the metal is needed, especially when the corrugations are deep. Iron is the chief metal thus treated; though there is nothing to prevent the application of the process to copper and other metal. The iron may be galvanised or coated with a film of zinc, to render it more weather-proof; but this process is not necessarily connected with corrugation. The uses of corrugated iron are now very numerous, seeing that the material acquires, in practical construction, a degree of strength altogether beyond that which belongs to the mere thickness of the sheet. It will form either a wall or roof, with very little support from other sources. Railway travellers have become accustomed to the use of this material in the sides and coverings of ticket-platforms, in the sides of carriage sheds, and in the roofs and appendages of stations. In dockyards and other large establishments, it is much employed for light and temporary structures. Temporary churches are in part made of it. It is used also for emigrant houses and storerooms.

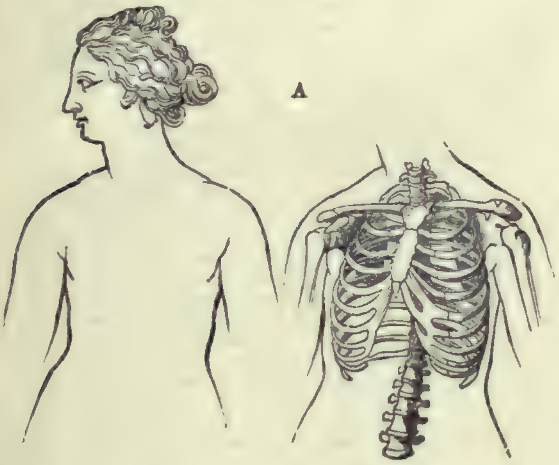
An American inventor, Mr. Joseph Francis, of New York, has devised a remarkable mode of applying corrugated sheet-iron to the construction of very light and buoyant boats, available as safety-boats, and for other purposes. Captain Portlock has described the difficulties attending this application, and the ingenious way in which those difficulties have been surmounted. By corrugating the iron, the flexible sheet is rendered rigid as the surface is bent, so as to produce longitudinally, in effect, a series of parallel girders or beams, and transversely a series of arches; but it is also evident that by thus rendering the sheet rigid, the difficulty of adjusting it to a curved or varying surface is greatly increased. Mr. Francis's mode of getting over this difficulty is a singular one. He produces the rigidity due to corrugation, and the form of the boat itself, by one simultaneous operation. For this purpose, he prepares pressing or stamping apparatus, in the form of enormous dies, and corresponding in shape and size with the boat to be made, with grooves to represent the corrugations. The plain sheets of iron being placed between the two dies, or the die and counterdie, and subjected to a powerful hydrostatic pressure, are at the same time shaped and corrugated. In the earlier experiments, however, he found that the same breadth of metal being required to be adjusted to different spaces, the surfaces became wrinkled, overlapping the lesser spaces. This obstacle he removed by adjusting the gauge of the corrugations to the position of the sheet; and thus, as it were, not only swallowing up the superfluous metal, but giving more strength to the parts requiring it. The theory of this construction is, that the combined curves and corrugations give so much strength to a boat of small size, as to render all internal bracings and strengthenings unnecessary. Major Vincent Eyre, in a paper read before the British Association for the Advancement of Science at the Cheltenham Meeting in 1856, gave an account of these corrugated boats which, if not too highly coloured, denotes the combination in them of many very remarkable qualities. Two trials of boats were made, one at Liverpool and the other at Woolwich, "On both occasions the tests were such as not even the strongest wooden boat that was ever built could have sustained without going immediately to pieces. For instance, being manned by a full crew, they were rowed several times with full speed against the stone-work of the dock; they were tossed over and over with excessive violence on the stone pavement; they were filled with large blocks of stone placed midships and piled up to a considerable height, and then hoisted up by tackle head and stern; they were battered on the sides by large hammers on one spot, with all the force a strong man could muster—but all without producing the slightest injurious effect. At the end of this rough treatment, they were found perfectly whole and watertight." This authority summed up his encomiums by declaring the corrugated boats to be fire-proof, water-proof, worm-proof, incorrodible, liable neither to warp nor to split: strong, light, buoyant, and cheap. Boats of this construction were used by Lieutenant Lynch, in the United States expedition to the Dead Sea and the river Jordan; they were impelled against rocks, dragged over shoals, swept down rapids and cascades, and exposed to other rough usage, which they bore well.

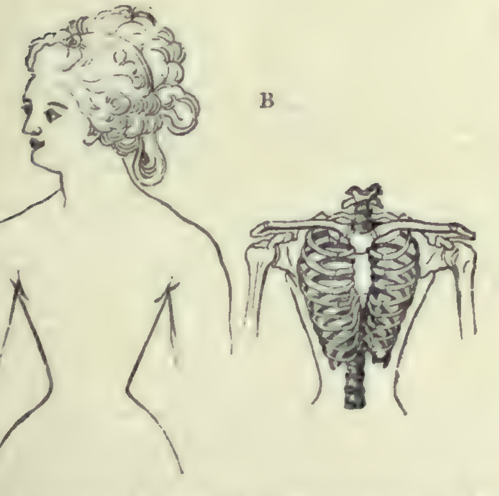
It has been suggested that corrugated iron, manufactured in this way, would render good service as a material for military waggons, which would either run upon wheels on land, or float on water, and thus serve as waggons, bridges, or boats.

CORRUPTION OF BLOOD. [ATTAINDER.]

CORSET, an article of dress for compressing, under the pretext of supporting, the chest and waist, worn chiefly by females, but also sometimes by effeminate individuals of the other sex. It consists of cloth made to surround the body, stiffened by whalebone or other means, and tightened by a lace. It seems a remnant of the old practice of enveloping the whole frame in swaddling bands; a practice which has been generally discarded in rearing male children, but which still lingers as a part of the attire of female children, in defiance of nature, reason, and experience. The advantages arising from its use are trifling, if any; the disadvantages, manifold and serious. Nature has formed the chest (in which are lodged the lungs for respiration and the heart for circulation, two out of three of the vital functions) in the shape of a truncated cone, the base of which is capable of being alternately widened and contracted during inspiration and expiration. The wonderful and perfect mechanism for carrying on respiration cannot come into full play if any compression be applied to the lower part of the chest, which is however the part commonly selected, from yielding most easily, to endure the hurtful restraint of tight lacing. The chest never being allowed to expand to the extent which is necessary, the defect in each respiration is attempted to be compensated for by their greater frequency, and thus a hurried circulation is produced. The heart is also hindered in its action, and an imperfectly aërated blood is circulated by it, by which nutrition is inadequately accomplished: unhealthy secretions are likewise formed out of this vitiated blood, and prove a further source of disease. The muscles of the chest, spine, and abdomen, being deprived of their proper exercise, become attenuated and feeble, and incapable of giving due support, whence result distortions of the spine and chest, and much of that constipation which so frequently afflicts females. The viscera of the abdomen, especially the liver, suffer greatly, both by displacement—being forced downwards—and by being actually indented by the edges of the compressed ribs. "In examining," says Dr. Hodgkin, whose connection with Guy's Hospital gave him extensive opportunities of observation, "the bodies of the dead, I have frequently found the lower ribs of females greatly compressed and deformed. I have repeatedly seen the liver greatly misshapened by the unnatural pressure to which it had been subjected, and the diaphragm or midriff very much displaced." The diseases which result from this interference with nature are various; and though they do not all occur in every female who adopts this mischievous practice, yet on inquiry too many may be traced to this source. Of these diseases consumption is the most frequent and fatal. Nor is the real object of all this painful and irksome compression in any instance attained. The figure of the female bust may be altered by it, but not improved. Sculptors, who are the closest observers of nature, and who transfer to their statues every beauty presented to their eye, have invariably given ample dimensions to the lower part of the chest. The more therefore any female, not of unnatural proportions, compresses her waist, the more does she depart from resemblance to "the statue which enchants the world."

The accompanying figures, the first, A, representing the Venus de' Medici, and the skeleton in its natural form; the second, B, the form as altered by the use of tight stays, taken from Professor Soemmering, 'On the Effects of Stays,' will illustrate this.





CORTES, the name of the assembly of representatives of the Spanish nation. These assemblies have been variously constituted in different ages, and in the different kingdoms into which Spain was divided till the time of Ferdinand and Isabella. The cortes of Castile and Leon and those of Aragon were the principal. Considerable obscurity prevails as to the origin and the formation of both. The earliest national assemblies under the Visigothic kings met generally at Toledo: they consisted chiefly of the dignitaries of the church, and were called councils. After deciding all questions of church discipline, they concerned themselves with temporal affairs, and in this stage of the discussion the lay lords or barons took an active part, and the king presented his requests. In the acts of the council of Leon, A.D. 1020, ch. vi., the transition from ecclesiastical to temporal affairs is clearly pointed out: "Judicato ergo ecclsiæ judicio, adeptaque justitia, agatur causa regia, deinde populorum." In the acts of the council of Jaca, 1063, we find that several points of discipline were reformed "with the consent of the nobles and prelates;" and the signatures are those of the king, the infantes, nine bishops, three abbots, and three magnates; but it is added in a note that "all the other magnates had subscribed to the same acts." It is now generally acknowledged, that in that age, and down to the end of the 12th century, there was no popular representation from the towns or commons of Castile and Leon in those assemblies. (Marina, 'Teoria de las Cortes;' Sempere, 'Histoire des Cortes;' Prescott's 'History of Ferdinand and Isabella,' and 'Hist. of Philip II.') The people are said to have occasionally attended these national councils on some solemn occasions, as in the council held at Toledo in 1135, but only as spectators and witnesses, "to see, to hear, and to praise God." By degrees, as the towns rose into importance, and obtained local fueros, or charters, from the kings for their own security, or formed themselves into fraternities for their mutual protection against the Moors or against the violence of their own nobles, some of them obtained at last the privilege of sending deputies to the national councils, which were now styled cortes, because, according to some etymologists, they were held at the place where the king had his court. The cortes held at Salamanca by Ferdinand II., in 1178, consisted only of the nobility and clergy; but at the cortes of Leon, in 1188, we first hear that there were present deputies "of towns chosen by lot;" and in the same year the Cortes of Castile assembled at Burgos, where deputies from about fifty towns or villages, the names of which are mentioned, were present. How these places came to obtain this privilege is not known, although it is probable that it was by the king's writ or by charter. The cortes were henceforth composed of three estamentos or states, clergy, lords, and procuradores, or deputies from the enfranchised towns, forming together one chamber, but voting as separate states. It was a standing rule that general laws must have in their favour the majority of each estamento. This was the principle of the cortes of the united kingdom of Castile and Leon. The same principle existed in the kingdom of Aragon, only there the cortes were composed of four brazos or states,—namely, the prelates, including the commanders of the military orders; the ricos hombres, or barons; the infanzones, or caballeros, who held their estates of the great barons; and lastly, the universidades, or deputies of the royal towns. These last are first mentioned in the cortes of Monzon, in 1131. The towns and boroughs in Aragon which returned deputies were thirty-one; but the number of deputies returned by each is not defined by the historians, any more than those for the cortes of Castile. We find the same town returning sometimes a greater, sometimes a smaller number, and at other times none at all, and a small town or village sending more deputies than a large one; while many considerable towns never returned any, independently of the seignorial towns, which of course had no representative privilege. How all this was made to agree with the manner of voting, in order to ascertain the opinion of the majority, is not clearly stated.

In Castile, from the end of the 13th century, the popular estamento made rapid strides towards increasing its influence, being favoured in this by some kings or pretenders to the crown, such as Sancho IV. and Enrique II., or taking advantage of disputed successions and stormy minorities to obtain from one of the contending parties an extension of their privileges. In 1295 the deputies of thirty-two towns and boroughs of Castile and Leon assembled at Valladolid, and entered into a confederacy to defend their mutual rights against both the crown and the nobles. Among many other resolutions, one was, that each of the thirty-two constituencies should send two deputies every two years to meet about Pentecost at Leon or some other place, in order to enforce the observance of their stipulations. In 1314, during the frightful confusion which attended the minority of Alonso XI., we find another confederacy between the nobles and the procuradores of 100 communities, with a similar clause as to deputies meeting once or twice every year. These meetings of deputies for special purposes ought not to be confounded with the general cortes of the kingdom, which were always convoked by the king, though at no fixed times. Enrique II. having revolted against his brother, Pedro the Cruel, courted the support of the municipal towns, which at the cortes of 1367 demanded the admission *de jure* of twelve deputies into the royal council, which had till then consisted of hereditary nobles and prelates, with occasionally some civilians called in by the king. Enrique promised to comply with their request, but his brother's death having ensured his seat on the throne, he evaded the fulfilment of his promise by creating an Audiencia real, or high court of appeal, consisting of prelates and civilians, and a criminal court of eight alcaldes, chosen from different provinces of the kingdom. Juan I., who succeeded him after the loss of the battle of Aljubarrota, created a new council in 1385, consisting of four bishops, four nobles, and four citizens, with extensive executive powers. The towns next solicited the dismissal of the bishops and nobles from the council, in order that it should consist entirely of citizens; but Juan rejected the demand. "The 14th century seems to have been the brightest period of popular, or more properly municipal, representation in Spain. The cortes were frequent, and the subject of their deliberations of the most important nature. But Spain had never a definite representation; to no meeting of this period did all or half the great towns send deputies, and those which did return them appear to have observed little proportion in the numbers." (Dunham's 'Hist. of Spain and Portugal.')

The remonstrances or petitions of the general cortes to the king generally began as follows: "The prelates, lords, and caballeros of the kingdoms of Castile and Leon, in the name of the three estates of the kingdom," &c. Remonstrances from the deputies of the towns began: "Most high and powerful prince! your very humble vassals, subjects, and servants, the deputies of the towns and boroughs of your kingdoms, who are assembled in your presence by your order," &c. (Cortes of Valladolid, June, 1420.)

In the cortes of 1402, Enrique III. demanded for his wars with the Moors a supply of 60,000,000 of maravedis, but the deputies granted only 45,000,000. By his testament, Enrique excluded the citizens from the council of regency during the minority of his son, Juan II., and after this they were no longer admitted into the royal council. Thus the municipal towns lost a great advantage they had gained thirty years before under Juan I. They soon after sacrificed of their own accord their elective franchises. The expenses of the deputies to the cortes had been till then defrayed by the towns; but now, having lost their influence at court by their exclusion from the royal council, the towns began to complain of the burden. Juan II. listened attentively to their complaints, and, in the cortes of Ocaña, 1422, he proposed that the future expenses of the deputies should be defrayed out of the royal treasury, a proposal which was willingly accepted. Accordingly, in the next cortes, twelve cities only (Burgos, Toledo, Leon, Zamora, Seville, Cordova, Murcia, Jaen, Segovia, Avila, Salamanca, and Cuença) were summoned to send their deputation. Some other towns were informed that they might intrust their powers to any deputy from the above. The privilege was subsequently extended to six more cities—Valladolid, Toro, Soria, Madrid, Guadalaxara, and Granada. These eighteen places constituted henceforth the whole representation of the kingdoms of Castile, Leon, Galicia, and Andalusia. The other communities, at last perceiving the advantage they had lost, petitioned to be restored to their right, but found themselves strenuously opposed by the privileged towns. The influence of the court was openly exercised in the elections of these towns, and although the cortes of Valladolid in 1442, and those of Cordova in 1445, requested the king to abstain from such interference, yet the practice became more barefaced than ever. In 1457 Enrique IV. wrote to the municipal council of Seville, pointing out two individuals fit to be deputies in the next session, and requesting they might be elected. Thus long before Charles I. (the Emperor Charles V.), who has been generally accused of having destroyed the liberties of Spain, the popular branch of the representation was already reduced to a shadow; for the deputies of the eighteen cities elected by court influence, were mere registrars of the royal decrees, and ready voters of the supplies demanded of them. Under Ferdinand and Isabella the royal authority became more extended and firmly established by the subjection of the privileged orders. Charles only finished the work by excluding the privileged orders from the cortes altogether; he and his successors contenting themselves with convoking the deputies of the eighteen royal cities of the crown of Castile on certain solemn occasions, to register their decrees, to acknowledge the Prince of Asturias as heir apparent to the throne, to swear allegiance to a new sovereign, &c.

In Aragon, Valencia, and Catalonia, which formed the dominions of the crown of Aragon, the cortes of each of these three states continued to assemble under Charles I. and his successors of the Austrian dynasty, who convoked them in their accustomed manner by brazos or orders, and they maintained some show of independence, although in reality much reduced in importance, after Philip II. had abolished the office of the Justiza. [ARAGON, in GEOG. DIV.] But after the War of the Succession, Philip V. of Bourbon formally abolished the cortes of these states by right of conquest, as he expressed it, because they had taken part with his rival, the Archduke Charles.

When, in 1808, the Spanish people rose in every province against the invasion of Napoleon, the king was a prisoner in France, after having been obliged by threats to abdicate the crown, and the nation found itself without a government. Municipal juntas were formed in every province, consisting of deputies taken from the various orders or classes of society,—nobles, clergymen, proprietors, merchants, &c. These juntas sent deputies to form a central junta, with executive powers for the general affairs of the country; but a legislature was still wanting. The central junta was called upon to assemble the cortes for all Spain. They at first thought of reviving the ancient cortes by estamentos or brazos, but many difficulties presented themselves. The difference of formation between the old cortes of Aragon and those of Castile; the difficulty of applying those forms to the American possessions of Spain, which were now, for the first time, admitted to equal rights with the mother country, but where the same elements of society did not exist,—at least not in the same proportion; the difficulty even in Spain of collecting a legitimate representation of the various orders, while most of the provinces were occupied or overrun by French armies, and while many of the nobility and the higher clergy had acknowledged the intrusive king Joseph Bonaparte; all these, added to the altered state of public opinion, to the long discontinuance of the old cortes by orders or states, to the diminished influence of the old nobility, and the creation of a new nobility during the latter reigns merely through court favour, made the original plan appear impracticable. The situation of the country was, in fact, without a parallel in history. The central junta consulted the consejo (reunido), or commission of magistrates, from the old higher courts of the monarchy, who proposed to assemble deputies of the various brazos or estamentos, all to form one house,—a proposal extremely vague and apparently impracticable, which looks as if made to elude the question. Jovellados and others then proposed two houses, constituted as in England; but this would also have been a new creation without precedent in Spain, and surrounded by many difficulties, the state of society being very different in the two countries. Meantime the central junta being driven away by the French, first from Madrid, and afterwards from Seville, in January, 1810, took refuge at Cadiz, which became the capital of the Spanish patriots, whither a number of persons from the various provinces and classes had flocked. Soon after arriving at Cadiz it resigned its powers into the hands of a council of regency composed of five individuals, who issued letters of convocation for the deputies of all the provinces to assemble in cortes at the Isla de Leon on the 24th September, 1810.

The cortes, styled "extraordinary," sat at Cadiz from September, 1810, till September, 1813. During this time, amidst numerous enactments which they passed, they framed a totally new constitution for Spain, which has become known by the name of "the constitution of 1812," the year in which it was proclaimed. This constitution established the representative system with a single popular chamber, elected in a numerical proportion of one deputy for every 70,000 individuals. The extraordinary cortes of Cadiz were succeeded in October, 1813, by the ordinary cortes, elected according to the principle of the constitution. In March, 1814, King Ferdinand returned to Spain, and soon after dissolved the cortes, abrogated the constitution, and punished its supporters. In 1820 the constitution was proclaimed again through a military insurrection; the king accepted it, and the cortes assembled again. The king and the cortes, however, did not remain long in harmony. In 1823 a French army, under the duke of Angoulême, entered Spain; the cortes left Madrid, taking the king with them to Seville, and thence transferred him by force to Cadiz. Cadiz having surrendered to the French, the cortes were again dispersed, and the constitution was again abolished.

Ferdinand VII., before his death, assembled the deputies of the royal towns, according to the ancient form, not to deliberate, but to acknowledge as his successor his infant daughter Isabella. On April 10, 1834, the queen regent proclaimed a charter for the Spanish nation, which was called Estatuto Real. It established the convocation of the cortes and its division into two houses, the procuradores, or deputies from the provinces, and the proceres, or upper house, consisting of certain nobles, prelates, and also of citizens distinguished by their merit. The power of the cortes, however, was very limited, the initiative of all laws belonging exclusively to the crown. This charter did not last above two years. In the summer of 1836 insurrections broke out at Malaga and other places, where the constitution of 1812 was again proclaimed; and at last the insurrection spread among the troops which were doing duty at the queen's residence, at La Granja, in consequence of which the queen accepted the constitution, "subject to the revision of the cortes." The cortes were therefore convoked according to the plan of 1812; and early in 1837 they commenced their duties, forming a constitution which was decreed on June 16. By this the cortes were to consist of a senate and congress of deputies; each province was to return three persons as senators, of whom the sovereign was to select one: and there was to be one deputy for every 50,000 souls of the population. The deputies were to be elected for three years, and the cortes were to meet every year. Laws relating to taxes and public credit were to be first submitted to the deputies, and if altered in the senate were to be returned to the deputies for their ultimate decision. This constitution was in force till Dec. 27, 1843, when the sittings of the cortes were suddenly suspended by a decree; but in 1844 a new cortes was summoned, at which it was proposed that the senators should be named by the crown for life; that the cortes, instead of meeting every year, should only be at the pleasure of the crown; and that the political offences of the press should not be submitted to a jury; and in March, 1845, other regulations were enacted relating to the qualifications of deputies and electors. On the suppression of the Carlist war the cortes were re-established in 1848, with considerable power by Espartero, who became himself the victim of the party feeling prevailing among its members. Since that time they have been accustomed to meet, and to debate, but have generally been under some sinister influence, either the power of the army or the corruption of the ministry, and have on the whole played a very insignificant part in the history of their country during the last twenty years.

The history of the cortes of Portugal is nearly the same as that of those of Spain, only that the towns which sent deputies were comparatively fewer, seldom more than ten or twelve at a time, and the influence of the privileged orders greater in proportion. The nobles having by degrees become courtiers, as in Spain, the kings reigned in fact absolute. In 1820, while King João VI. was in Brazil, a military insurrection broke out in Portugal, and a constitution was framed in imitation of the Spanish one of 1812, but it was soon after upset. For an account of these transactions see Kinsey's 'Portugal Illustrated,' 1828. After the death of King João, his son, Don Pedro, gave a charter to Portugal, establishing a system of popular representation with two houses; this charter was afterwards abolished by Don Miguel, again re-established by Don Pedro; and has been maintained, with a short interruption in 1836, by Queen Maria and the present king.

The Aragonese, during their period of splendour, extended their representative system by brazos or estamentos to the island of Sardinia, then subject to the crown of Aragon, and the institution remained till lately under the name of Stamenti. They were convoked by the crown on particular occasions, chiefly to grant extraordinary supplies, but have been now replaced by a representative assembly, meeting at Turin. [SARDINIAN STATES, in GEOG. DIV.]

CORTICIN. An inodorous, tasteless substance, said to exist in the bark of the aspen-tree.

CORVUS, the Crow, sometimes *Hydra et Corvus*, because this constellation, in fact, contains a part of the body of Hydra, on which the bird rests. In Aratus, Hydra, Crater, and Corvus form one constellation. There are mythological stories, apparently not very ancient, in Hyginus.

Character.	No. in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.
α	1	4090	4
ε	2	4097	4
γ	4	4124	3
δ	7	4211	3
β	9	4234	3

CORYDALINE ($C_{43}H_{27}NO_{18}$?). An alkaloid contained in the root of the *Corydalis bulbosa*, as also in snake-root (*Aristolochia serpentaria*). It is a gray, light, non-coherent substance, soluble in alcohol and ether, but insoluble in water.

COSECANT, COSINE, &c. [TRIGONOMETRY.]

COSMO′GONY, in the proper sense of the term, is the science of the creation of the world. As the creation of the world was not observed by man, and as it is not possible for man to observe the creation of a world, so cosmogony cannot be a science founded on direct experience, but must necessarily be a philosophical science. But though cosmogony belongs to the department of philosophy, yet, as it requires an accumulation of facts and observations to rest on, it must still be classed under the division of practical philosophy. The ancients not possessing these facts and observations, cosmogony has only become a science in modern times. The German philosopher Kant has denied the capacity of the human mind to entertain this science.

The doctrine of the creation of the world may be considered in three ways; the inquirer either confines himself to the creation of our earth, and reduces cosmogony to geognosy, geogony, speculative geology, and oryctognosy (which latter is a science of itself), or he may merely investigate the creation of celestial bodies, or he may extend his researches to the origin of creative power, and the creation of the elements of matter.

The first of these modes of investigation is pure cosmogony; the second is a union of cosmogony with dynamogony, physiogony, and speculative chemistry and physics. The ancients speculated or dogmatised in both these divisions of the science, with no very satisfactory results. The chief modern cosmogonists may be divided into two classes; first the dogmatists, as Buffon, in his 'Histoire Naturelle;' Wolff, in his 'Cosmologia;' Maupertuis, in the 'Essai de Cosmologie;' Lambert, in the 'Kosmologische Briefe;' Dalberg, in the 'Betrachtungen über Universum;' Berger, in his 'Philosophische Darstellung des Weltalls,' Des Cartes, 'Opera Omnia,' lately edited by Victor Cousin; and Hollbach, in the 'Système de la Nature.' Secondly, the critical cosmogonists, who conduct their inquiries according to the principles of Kant, as developed in his 'Allgemeine Naturgeschichte, und Theorie des Himmels;' and in detached parts of the philosophical systems of Schelling, Hegel, Herbart, and in the 'Naturphilosophie' of Oken, which contains a complete system of cosmogony, dynamogony, and physiogony; and in a work of John Müller, entitled 'Ueber die Entstehung der Welt aus Nichts.'

COSMOGRAPHY (*κοσμογραφία*), the description of the system of the world, from the two Greek words *γράφω*, to write, and *κόσμος*, which signifies the world, or the universe, considered as a system of order. Cosmography, strictly limited, has nothing to do either with the origin and creation of things, which is the subject of cosmogony, or with the metaphysical philosophy of the constitution of things, which is cosmology. It is merely the description of the system of the material world, as it is, or as it appears to our senses. Nor does it comprehend any examination of the separate parts of the system, except in so far as each is connected with the whole, any more than the description of a machine comprehends any account of the wood or iron or other material of which it may be fabricated. Yet this distinction has been sometimes neglected. There is a work, for instance, by Paul Merula, under the title of 'Cosmographia Generalis,' fol. Amst. 1621, which is in the greater part merely a description of the different countries of the earth, or in other words a treatise on geography. In like manner, the English work of Dr. Heylin, first published in 1622, under the title of 'Microcosmos,' and afterwards under that of his 'Cosmography,' is merely a compilation of geography and history. The word cosmography may perhaps legitimately admit of some variety of acceptation, in regard to the extent of what is to be considered the system of the world or of the universe. Of the universe absolutely we can of course predicate nothing; but as anything may be called the whole which can be regarded as complete in itself, so the word universe is applied sometimes to this globe alone, which in one sense is the universe to us, and sometimes to that solar system of which our globe is one of the parts. But the term cosmography might also, without impropriety, be used as meaning a view or description of any separate portion of the entire universe still more extensive than the solar system. The 'Cosmos' of Baron Alex. Humboldt is one of the most satisfactory examples of the proper mode of treating of cosmography, in its most comprehensive sense.

COSTS, in the technical sense of the word, are the expenses incurred by parties in proceedings at law or in equity. In civil actions particular importance and interest attach to the principles and practice concerning them, since though in themselves merely incidental and subordinate to the main cause of action, it not unfrequently happens that they become a prominent object of anxiety and contention. Under the head *Costs in civil actions* may be considered the steps by which the mutual rights and liabilities to them were originally created, and have been subsequently qualified; the modications to which those rights and liabilities are subjected by reason of the particular character in which the parties may sue or be sued; and the practice by which the amount of costs is ascertained and controlled.

At common law neither the plaintiff nor the defendant was entitled to recover costs the one from the other, as a matter of right; the only liability which attached to the unsuccessful party, beyond the direct result of the suit, being an amercement imposed upon him for his false complaint or defence. If, however, the plaintiff succeeded, the jury were at liberty, and were usually directed, to take his costs into consideration in estimating the amount of damages. And before there was any legislative enactment upon the subject, it is said that the justices in eyre, and afterwards those of assize and nisi prius, were in the habit of assessing the plaintiff his costs, exclusively and apart from the damages.

The first statutory provision with respect to costs was that of the Statute of Marlbridge (52 Hen. III. c. 6), which gave them to the defendant in one particular case (wardship in chivalry), which became extinct in the reign of Charles II. Then came the Statute of Gloucester (6 Edw. I. c. 1), by which a successful plaintiff recovered the costs of his suit in all cases where he was previously entitled to recover damages. The right to costs under this statute, which were styled costs of *increase*, was entirely independent of the amount of damages recovered. The consequence of this being found mischievous, power was given to the judges by the stat. of 43 Eliz. c. 6, s. 2, in all personal actions, except such as concerned the title or freehold of land, and those of battery, where the debt or damages did not amount to 40*s*., to grant a certificate of that fact, and to award to the plaintiff no greater or more costs than the sum of the debt or damages recovered should amount to, but less at their pleasure. Owing to the indisposition of the judges to grant certificates under this statute, it was for some time wholly inoperative, and it was therefore enacted by the statute of 22 & 23 Car. II. c. 9, s. 136, that in all actions of trespass, assault, and battery, and other personal actions, where the jury should find damages under 40*s*., the plaintiff should recover no greater costs than damages, unless the judge should certify that an assault and battery were sufficiently proved, or that the freehold or title of land was chiefly in question. It has been observed of this statute, with great show of reason, that the legislature intended by it to preclude the plaintiff absolutely from recovering full costs, where the damages were below 40*s*., in all personal actions but those specially named, and even in them, unless the judge *gave* them by a certificate under the Act. It received, however, a different construction from the courts, by which it was held to apply to those actions only in which it was possible to grant the prescribed certificate, all others being left to the provisions of the previous statute. Wherever therefore it appeared, either from the form of the action, or from the pleadings, or the nature of the case, that no question of a battery, or of freehold or title of land, could possibly be involved in the dispute, so as to give the judge the option of certifying, it was held that the plaintiff would be entitled to full costs, notwithstanding the statute.

By the statute of 8 & 9 Will. III. c. 11, full costs were given to the plaintiff in actions of trespass, where the judge should certify that the trespasses were wilful and malicious.

In the particular case of actions for oral slander of the person, where the words are actionable in themselves, either from their own intrinsic meaning, or from having been spoken of a party in reference to his profession or trade, the plaintiff's right to more costs than damages, where the latter fall short of 40*s*., is absolutely barred by the statute of 21 Jac. I. c. 16.

Hitherto those statutes only have been considered which relate to a *plaintiff's* right to costs. The first Act which recognised the interest of *defendants* in personal actions was one passed in the twenty-third year of Henry VIII., which, jointly with another Act of the reign of James I., gives costs to the defendant where the plaintiff is nonsuited or has a verdict passed against him, in all cases in which the plaintiff would have been entitled to them if he succeeded. By a subsequent enactment of the reign of Elizabeth, costs are given to the defendant where the plaintiff is guilty of delay or discontinuance in his suit. The defendant's right to costs was farther extended by the 3 & 4 Will. IV. c. 42, which gives him costs in cases where the plaintiff enters a *nolle prosequi*, or remits his suit. The same Act gives reasonable costs to one or more of several defendants sued together, who shall have a *nolle prosequi* entered as to him or them, or upon trial of the action shall have a verdict pass for him or them, unless the judge shall certify that there was reasonable cause for joining him or them in the action.

In the late very important changes which have been made with regard to the mode of pleading in civil actions, the courts have taken great pains to provide a more equitable apportionment of costs between the parties than was formerly observed. It is enacted (C. L. P. Act, 1852, s. 81) that the costs of any issue, either of fact or law shall follow the finding or judgment upon such issue, whatever may be the result of other issues.

To render the costs of legal proceedings in some degree at least commensurate with their object, there is a standing direction to the taxing officers to tax a successful plaintiff's costs upon a lower scale where he has recovered a debt of less than 20*l.*, unless a certificate for costs upon the ordinary scale be granted by the judge of the superior court before whom the cause was tried.

In actions brought in the superior courts for causes within the ordinary jurisdiction of the county courts, where the plaintiff recovers a sum not exceeding 20*l.*, in actions based upon contract, or not exceeding 5*l.* in actions based upon tort, he has judgment to recover that sum only, and no costs, except where a judge certifies that there was sufficient reason for bringing the action in such superior court, or where an order for costs is made by a superior court, or a judge thereof, upon the ground that there was such sufficient reason, or that no plaint could have been entered in a county court, or that the action was removed into the superior court by certiorari, or that the plaintiff dwelt more than twenty miles from the defendant, or that the cause of action did not arise wholly or in some material point within the jurisdiction of the court within which the defendant dwelt or carried on his business at the time of the action brought, or that an officer of the county court was a party, otherwise than in respect of claims to goods seized under county court process or to their proceeds. Where no such certificate or order is made a successful defendant is entitled to his costs as between attorney and client.

The provisions of "The London (City) Small Debts Act, 1852" (15 & 16 Vict. c. 77), which regulate the costs recoverable in the superior courts in cases within the ordinary jurisdiction of the City Small Debts Act, are very peculiar, but are of too limited application to justify explanation here.

As to the manner in which the right or liability of a party to costs may be modified by the particular character which he sustains, a striking instance used frequently to occur in former days, in the case of plaintiffs suing in the representative character of executors or administrators. In favour of such parties it was held, that wherever they sued for a cause of action which they could not have recovered in their individual capacities, they would not be liable to the defendant for costs, upon being nonsuited, or having a verdict pass against them. For some time a notion prevailed that this exemption proceeded from a consideration of the degree of ignorance under which they were supposed to lie with respect to the contracts or other causes of action of the deceased parties whom they represented. But the sounder opinion at length obtained, that the true cause of this freedom from liability was to be found in the particular language of the different enactments bearing upon the subject.

After having been long considered too extensive, this privilege has been effectually curtailed by the 3 & 4 Will. IV. c. 42, s. 31, which puts executors and administrators upon the same footing with other plaintiffs, unless the judge before whom the action shall be brought, or a judge of any of the superior courts, otherwise orders. The disposition of the courts, with regard to this Act, is not to interpose in behalf of the plaintiff, unless the defendant has brought the action upon himself by practising something like a fraud upon the plaintiff, thus discouraging the practice formerly prevalent of bringing merely speculative actions in a representative character, under the shelter of immunity from costs.

In penal or *qui tam* actions, the plaintiff's right to costs depends altogether upon the provisions of the statute which creates the cause of action. There are also express statutes which impose additional liabilities upon a plaintiff of this class under certain circumstances. There are, moreover, numerous enactments relating to costs in particular actions, and in actions against persons clothed with special statutory authority, too minute for detail here.

When a party has obtained the permission of the court to sue *in formâ pauperis*, that is, to be provided, on account of his poverty, with all necessary writs, as well as with counsel and attorney, gratis, he is not liable to pay any costs, nor is he entitled to receive them unless by order of the court or a judge.

The mode in which the amount of costs payable between the parties is ascertained, is by taking the Nisi Prius records, with all the papers, briefs, and other documents, to the proper officer, or taxing master, of the court, who then taxes the costs according to a certain prescribed scale, allowing or disallowing particular charges at his discretion, subject to review by the court or by a judge sitting in chambers.

Hitherto we have only considered *single* costs, or those derived from the Statute of Gloucester. In some cases *double* and *treble* costs are expressly given by statute; and wherever a statute gives double or treble damages, the plaintiff was also entitled to double or treble costs. But now, by 5 & 6 Vict. c. 97, s. 2, a party entitled to *double* or *treble* costs under any public general Act is to receive in lieu thereof reasonable indemnity as to his costs, to be taxed by the ordinary officer; and all provisions in local or private Acts for *double* or *treble* costs are, by sec. 6 of same Act, repealed.

Such are some of the principal matters relating to costs in actions at law,—a subject so purely technical in its nature, that any minute inquiry into its rules and mode of administration would be foreign to the purposes of this work. Between the courts of equity and those of common law there is this important difference with respect to costs, that the former are not bound by any of the enactments above enumerated, but are invested with a discretionary power upon the subject. In the exercise of this power they are guided, not merely by the event of the suit, but by a consideration of its real merits, and of the interests of the parties concerned. Thus, although the party failing is *primâ facie* liable for the costs, he will be relieved from the burden if he has prosecuted the suit in the conscientious discharge of a duty imposed upon him as a trustee for the benefit of others. On the other hand, a party proceeding erroneously will not be allowed the costs of his erroneous proceedings, even though the decree of the court may ultimately be in his favour.

In proceedings whereto the crown was a party, the old rule was that it neither received nor paid costs. This was long felt to be both oppressive in practice and unjustifiable in principle; and by a recent statute, 18 & 19 Vict. c. 90, it is provided that in all informations, actions, suits, and other legal proceedings of a civil or *quasi* civil character, the crown shall receive or pay costs, according as it succeeds or fails.

In *criminal proceedings* the rights and liabilities of parties to costs depend altogether upon express statutory enactments. With a view to forward the ends of justice, provisions have been made by various statutes to defray, out of the funds of the county, at the discretion of the court, the expenses incurred by prosecutors and their witnesses in cases of felony.

For the practice respecting costs in special cases, see the various titles throughout the work,—BANKRUPTCY; CERTIORARI; MANDAMUS, &c.

COTARNINE. [OPIUM, *Alkaloids of.*]

COTE' DROITE, COTE' GAUCHE, the names given to the two great divisions of the Chamber of Deputies, or French representative assembly, during the existence of the Charte. They took their names from sitting on the right or left of the president, and represented what in the English House of Commons are styled the ministerial and opposition benches. There were also subdivisions of the extrême droite and the extrême gauche, the centre droite and the centre gauche, denoting the ultras of each party, or the independents. In the present chamber of deputies these party distinctions are out of use; under the restrictive system of election the opposition members are too few to constitute a division.

COTTAGE ARCHITECTURE. The term "cottage" has so very wide an application that it is difficult to assign any very definite limits to the style of architecture appropriate to it. There are "cottages with three-stalled stables, cottages of gentility," and there are cottages designed expressly for the residences of the labouring agricultural population in those districts where the wages of day labour are so low as to keep their recipients constantly on the verge of poverty. The former of these classes of cottages tread so closely on the heels of pleasure or country residences, that the consideration of their construction may fairly be left out of the present article; and it is proposed in the following remarks simply to notice the principles which should be observed in the construction of labourers' cottages,—starting always with the assumption that the proprietor of the land to be cultivated attaches more importance to the happiness and the respectability of the parties he employs than he does to the nominal money rental he may derive from his cottage property. Unfortunately, it is almost always the case that the wages of agricultural labourers are so low that they cannot afford to pay the money-rents which would be required to make cottage-building a remunerative and self-supporting operation; and therefore it is that attention should be directed towards rendering the contribution of the landlord as small as possible, by adopting every possible economy consistent with the attainment of the object of improving the moral condition of the tenants; and to endeavouring to bring the really remunerative rent within the capacity of the tenants, so as to develop in them the habits of independence and self-reliance, which are at the bottom of all honest and noble character. On these principles it is possible that the artistic beauty of the cottages may suffer, but so long as the residences themselves possess the requisite conditions of healthiness and comfort, they fulfil the strict necessities of the case; and it does seem to be desirable that anything beyond the details required for such purposes should be avoided, as they give a species of eleemosynary character to the houses which tends to degrade their inhabitants.

The style of architecture to be adopted in cottage-building must mainly be influenced by local considerations; that is to say, it must be regulated by the nature of the materials employed, by the surrounding scenery, or by any associated buildings. It is, however, essential to observe, that even in the most picturesque scenery simplicity and economy of construction must be studied rather than abstract picturesque beauty of outline. These common-place merits, it is to be observed, can be attained simultaneously with a considerable amount of architectural expression, if only due attention be paid to the choice of materials; but, unfortunately, it has been too often the case that great sacrifices have been made, and very complicated and costly details have been introduced, for the avowed object of giving a picturesque appearance to buildings which, generally speaking, are the most consistent with the ends they are designed to fulfil when they are simple and almost plain in their outlines. It should therefore be the aim of the architect to give to his cottages an air of substantial comfort; to produce broad, massive effects, without allowing any details to thrust themselves into notice. The shadows of his composition should be bold, without rendering necessary any peculiar modes of construction,—nay, rather they should be produced by the essential constructive parts of the building itself; whilst the style adopted should be such as to admit of the simplest mode of execution of the joiners' work and other practical details. Thus, for instance, it is preferable to make the roofs with broad, overhanging, dripping eaves, than to construct them with boxed gutters and parapet walls, and to make the openings of doors and windows with square heads rather than with circular or pointed arches; and these precautions may be observed whether the Italian or the later Gothic styles of architecture be adopted. As a general remark, it may however be stated, that extreme archæological correctness need not be aimed at in the construction of cottages; and that the main practical considerations which ought to be present in the architect's mind are, that the rooms themselves in the interior should be comfortable and well ventilated.

The labourers' cottages, intended for the habitation of married men and their families, should always present a living room large enough for the whole family to meet, and to cook their victuals in; a larder; a coal or wood store; and a privy or water-closet; together with a sufficient number of bed-rooms to allow of a separation at least of the sexes; and perhaps, as a rule, it may be said that at least three bed-rooms are required in order to maintain the proper decorum of family life; whilst certainly provision must be made for the removal, at once, from the inhabited part of the dwelling, of the refuse of the whole establishment. The minimum size which seems to be admissible for the living room of a family cottage, such as is above described, may be taken to be 13 feet long by 10 feet wide in the clear, by 10 feet high from floor to ceiling; and the sleeping apartments should be proportioned so as to allow, as nearly as may be, about 1000 cubic feet of space for each occupant, although, unquestionably, a much smaller space might occasionally be tolerated; and indeed, if efficient means of ventilation be provided, the cubical space per individual above allotted may safely be diminished one half. Of course, it would be preferable to erect the cottages of agricultural labourers on the system of what may technically be called *detached* or *semi-detached* cottages; but local and economical considerations must ultimately determine the selection of the practical solution to be given to this or to other similar questions. It is to be observed, nevertheless, that there is an economy in building a *row* of cottages rather than a series of detached residences; because, in the former, the construction of party-walls must always be less costly than the construction of a series of external walls; and therefore even the semi-detached cottages would, as commercial speculations, only be resorted to when it was known that the habits of the poorer classes of the population they were intended to lodge were such as to warrant the belief that they themselves would truly appreciate the advantages in the way of privacy which it confers. Precautions must at all times be taken to ensure a copious supply of water; provision must be made for washing and drying clothes, and, if possible, also for baking; a tool-house should be formed; but, before and above all things, attention should be directed to securing the efficient ventilation of the different apartments.

The reader may consult on cottage architecture, Loudon, 'Encyc. of Cott. Arch.,' 8vo, Lond., 1842; Gwilt's 'Encyc. of Arch.,' 8vo. Lond. 1854; 'Report of Poor-Law Commissioners on an Enquiry into the Sanitary Condition of the Labouring Population,' 1842; Roberts, 'Dwellings for the Labouring Classes,' 8vo, Lond. 1850.

COTTON. In the NATURAL HISTORY DIVISION of the ENGLISH CYCLOPÆDIA, under the heading GOSSYPIUM, is given an account of the botanical characteristics of the genus of plants to which the cotton tree belongs; and under COTTON, in the same division, will be found a description of the most important among the many species of that genus. It now falls within the scope of the present division to continue the subject, by treating of the most gigantic manufacture, perhaps, which the world has ever witnessed in one single country—the cotton manufacture of Great Britain; together with the developments of the same system in other countries. To render this large subject intelligible to the reader, it will be necessary to adopt a certain mode of classification. First, will be presented a general view of the operations for maintaining and increasing the annual supply of raw cotton for the use of manufacturers; next, will be given a popular description of the machines and processes of manufacture; and lastly, will be noticed the trading operations connected with the manufactured goods, in relation to quantities, kinds, persons, and places. These subjects will be treated in three successive articles:—COTTON CULTIVATION AND SUPPLY; COTTON MANUFACTURE; COTTON TRADE AND CONSUMPTION.

COTTON CULTIVATION AND SUPPLY. A striking picture of the present state of the cotton supply for the factories of Great Britain was presented by Mr. Dawson, in a paper read at the meeting of the British Association in 1856, 'On the Connection between Slavery in the United States and the Cotton Manufacture of the United Kingdom.' His statistics and reasonings tended to establish these five propositions: 1st. That cotton, from the conditions of climate necessary to its culture, cannot be grown in Europe; but that, on the other hand, with the single exception of the factories of the New England States of America, it is, and must long continue to be, manufactured almost exclusively in Europe. 2nd. That the present supply is chiefly raised, and for the present must continue to be raised, by slave labour; seeing, that while for fifty years we have sought over the whole earth for cotton, we have during that time continued to obtain from the slave states of the American Union a continually increasing proportion of our entire supply. 3rd. That two-thirds in number at least of the slaves of the United States have been called into existence, and are now directly or indirectly maintained, for the supply of cotton for exportation. 4th. That of the cotton thus exported, three-fourths at least in value are raised for, and sent to, this country alone. 5th. That of the entire quantity we import, four-fifths at least in value are thus derived from the United States. The summary assumed the following remarkable form: Two-thirds of all the slaves in the cotton-growing districts of the United States are employed in supplying raw material for the cotton manufactures of our own country; and four-fifths of all the cotton-workers in Lancashire and other northern counties are dependent on the supply which those slaves raise. Some of these statements and ratios may not be strictly correct, but the general result is sufficiently near the truth.

By what steps this gigantic state of things has been produced, and in what direction future changes will have to be sought, we shall now proceed to show, by a rapid glance at the chief cotton-growing districts of the world. This, however, may usefully be preceded by a few paragraphs relating to the culture.

The finest kind of cotton, which commands the highest price, is called "Sea-island cotton," from the circumstance of its having been first cultivated in the United States of North America, in the low sandy islands on the coast, from Charleston to Savannah. This variety will not flourish at a distance from the sea, and it is said that its quality is gradually deteriorated in proportion as the plants are removed from "the salutary action of the ocean's spray;" it succeeds best in South Carolina, Georgia, and Florida. This cotton is composed of filaments longer than those of any other variety; which circumstance, joined to its even and silky texture, fits it for the production of the finest yarns. The seed is black, and in the southern states of North America it is thence frequently called "black-seed cotton," to distinguish it from the short-staple cotton produced in the interior of those states, and which, from a like natural cause, is distinguished as "green-seed cotton." The seed of the sea-island cotton is sown every year; but the plant, when cultivated within the tropics, will live and yield harvests for several years in succession. It is supposed to have come originally from Persia. The plant was taken from the little island of Anguilla to the Bahamas for cultivation, and was first sent thence to Georgia in 1786; but it is not said how the seed found its way to Anguilla. The supply is small, and the price always relatively higher than other kinds. "Upland" or "Bowed Georgia cotton," the green-seed kind, has received its name of *upland* to distinguish it from the produce of the islands and low districts near the shores. The expression *bowed* was given as being descriptive of the means employed for loosening the seed from the filaments; this was accomplished by bringing a set of strings, attached to a bow, in contact with a heap of uncleaned cotton, and then striking the strings so as to cause rapid vibrations, and thus open the locks of cotton and cause the seeds to be easily separable from the filaments. The remaining kinds of cotton now brought to English markets are distinguished by names so plainly indicative of the countries of production, that it is not necessary to offer any description of them with that view.

To illustrate the operations in a cotton-field, it will suffice to select two examples—the short-staple upland cotton of the United States, which forms the bulk of all the cotton used in England; and the long-staple sea-island cotton, used for our finest muslins. The cultivation of all other kinds may be inferred from those two, sufficiently near for the wants of the general reader.

For cultivating the *short-staple upland* cotton, the planter prepares his land with a small plough, drawn by one or two mules, which walk rapidly over the ground. A negro slave usually guides the plough. This preparation takes place during the winter months; it consists of a ploughing, a harrowing, a second ploughing, and a heaping-up into flat-topped ridges. The sowing takes place between March and May: the earlier the better, provided the winter frosts are gone. Some planters deposit the seed in furrows opened by a light plough; while others carefully dibble the seed at equi-distant intervals. The dibbling is considered the better of the two methods. A man proceeds rapidly along, making holes in the ridge with his dibble at intervals of twelve inches; a woman follows him, dropping five or six seeds in each hole; and a boy or girl comes in the rear, covering the holes with earth by a light hoe. By much practice under the eye of a vigilant overseer, the negroes become very expeditious in these processes. Drilling machines have not yet been found to work well; for the upland cotton-seeds being furred by the lint or fibre still adhering to them, and being very adhesive one to another, do not deliver well from the drill. When the young plants shoot forth, the weakest are cut away, leaving only two in each hole; and the holes which have failed are supplied by re-sowing; but the chief attention is bestowed on frequent weeding, which is essential to the cleanness and excellence of the crop. The weeding is mostly effected with the aid of light and straight hand-hoes. If the crop has pretty well escaped the attacks of vermin, insects, and storms, it is ready for picking in August. The plant continues to produce and ripen its bolls of cotton until the frost comes; and it is therefore a matter of nice calculation with the planter to delay his picking, so as to get as much as possible, and yet not to run the hazard of a frost. During the picking season, every hand is brought into requisition. Each picker fastens a bag round the waist, into which he (or she) throws the cotton bolls as they are picked; and when the bag is full, it is emptied out on a sheet; when the sheet contains as much as it will hold, it is carried to the weighing-house. A good hand will in a fair field pick 200 lbs. a day; but the average is less than this. Successive pickings are made as the bolls grow and ripen, until the quantity no longer pays for the labour. It is exceedingly difficult to state the average produce per acre: much of the land in Carolina and Georgia will only yield 100 lbs.; an excellent return in these states is 200 lbs.; the average in the teeming valley of the Mississippi is 400 lbs.; while careful culture on special spots is rewarded with a much higher return. Some of the plants, under favourable circumstances, will yield 400 bolls in one season, weighing 4½ lbs., which will afford 1½ lb. of ginned or cleaned fibre. The picking requires some dexterity; it is essential to get every particle of cotton from the boll at one pull, without any leaves or other foreign matter adhering to it. It is laborious work, on account of the stooping required; the pickers' hands become sore, and there is a liability to colds and rheumatisms, owing to the wetness of the bushes in the cold autumn mornings, occasioned by heavy dews at night. Some planters provide their slaves with waterproof aprons and skirts for this season; but others are not so considerate. When sufficient cotton has been collected, a machine called a *gin*, which costs the planter from 16*l.* to 24*l.*, is employed to separate the fibre from the seed. A screw-press, costing from 30*l.* to 50*l.*, is next employed to press the fibre into bales of about 400 lbs. each. Directly it is packed, the planter sends his cotton to market; and from the month of August to November the roads exhibit trains of waggons, carrying the cotton from the plantations to the shipping ports or the river stations. Mr. Leonard Wray, who has visited cotton plantations in various parts of the world, says, in relation to the upland cotton of America: "It is usual in the States to calculate the crop at so many acres to the working 'hand' (as the slave is denominated). Thus, a cotton-planter with 50 good working hands, great and small, and 25 mules, would consider his strength equal to 500 acres of cotton and 400 acres of corn, or to 1000 acres of cotton alone, provided extra hands are allowed for picking the crop. This is the general mode and rate of calculation where the soils yields about 200 lbs. of ginned cotton to the acre; making, therefore, to the 'hand' 2000 lbs. of cotton, which, at 5*d.* per lb. on the spot, is worth about 40*l.* sterling, besides the value of the Indian corn raised." Most cotton-planters grow corn enough for the supply of their slaves, and some have a large surplus for sale.

The *long-staple* or *sea-island* cotton, eagerly bought at a high price by the spinners of fine yarns for muslins and lace, is cultivated in the same general way as the short-staple, but with peculiarities which need only be glanced at here. According to the nature of the ground, as to level, moisture, and stiffness, the planter regulates the height of his ridges, the kind and amount of manure used, and the closeness of sowing. The produce is so much more valuable than upland cotton, that 200 acres of the one will have a money value equal to 1000 acres of the other; and thus it pays the sea-island cotton-planter to bestow much care on all his operations. The sea-island seed would admit of being sown by the drill; but there is very little machinery employed in the slave states, and most of the sowing is still effected by the dibble. The picking, as for the short-staple, usually commences in August, but requires much more care and attention. When picked, the bolls are slightly dried and examined to reject any which have become discoloured or injured in fibre. They are next kept for some time covered over in large heaps, to preserve the oiliness, strength, and gloss of the fibre, which would be injured by much exposure to the air; but this operation requires much caution, to prevent fermentation by heat, and the soiling of the fibre by the oozing out of oil from the seed. When the time for sending to market arrives, the cotton is taken from the heap and subjected to the ginning process, as a means of separating the fibre from the seed. The quantity of sea-island cotton grown being much smaller than that of upland, the processes are conducted on a less extensive scale; and the separation is usually effected, not by the gin, but by a more primitive instrument called the *churka*, similar to that which is employed by the Hindoos. This churka consists of two wooden rollers, eight or nine inches long by one inch in diameter, placed horizontally and in contact, one above the other; when these revolve, the fibres of cotton are drawn between them, and the seed left behind. The cotton is fed in by hand, while the rollers are made to rotate by means of a treddle. The machine will only clean from 12 lb. to 20 lb. in a day. Most of the planters adhere to this primitive method, under an impression that a more rapid or rough treatment would injure the delicate fibre of this highly-prized cotton. The correctness of this opinion is however denied by the more enterprising among the number, who use larger machines worked by steam-power, without any deterioration of the material. The cotton, cleared from its seeds, motes, and discoloured particles, is then pressed down into long cylindrical bags, quite different in appearance from those employed for upland cotton, and with less intense pressure, lest the fibre should be injured. The small quantity and high price of this variety render the market more uncertain than that of the coarser kinds. Mr Wray says on this subject: "After his produce is all fairly bagged, the difficulties of the planter are not ended; he has sometimes considerable trouble and has to wait a long time before he can find a buyer for it. Not unfrequently he has to ship it to Europe, and encounter manifold risks and chances. This, indeed, constitutes the greatest disadvantage under which he labours. The upland cotton planter makes his bale of cotton to-day, and to-morrow he has cash in hand for it; or perhaps he is even paid for it before it has left the trees. Not so, however, with the sea-island cotton planter; he is obliged to exercise all his patience before he can sell his crop; and in the meantime, although lord over 200 to 400 slaves and a fine estate, he is very probably compelled to use his broker's name in obtaining cash from the banks wherewith to pay the current expenses of his estate." The sea-island cotton yields more seed than the upland, and this seed is more smooth, clean, and oleaginous, thereby being better fitted for yielding cotton-seed oil. The produce is much less per acre of sea-island than of upland: 200 lbs. of clean fibre is about the maximum, while some fields barely yield 50 lbs.; the hands pick smaller quantities per day, and conduct the picking more carefully. The muslins, famous for their fineness, spun and woven by the Houldsworths and other firms who attend more particularly to this kind of work, are mostly made of sea island cotton. Small parcels of special excellence will sell for 3*s.* or 4*s.* a pound, while French lace-makers will sometimes give as much as 6*s.* One pound of such cotton can be spun into a *thousand miles* of yarn, which may be wrought up into lace worth 250*l.*

The present may be the most convenient place in which to advert to certain auxiliary commercial advantages resulting from the cultivation of cotton,—advantages not yet much attended to, but which may in future years possibly become very important. The fibre is, of course, the chief product for which the cotton-plant is cultivated, but it is not the only one. The plant yields a pure, bland oil, equal to that of the olive; an oil-cake, most excellent for feeding cattle; and a fibre from the bark, which would possess commercial value if collected and shipped. Even in the greatest of all cotton-growing countries, the United States, the oil contained in the seed has scarcely yet been rendered available; but Dr. James Coxe, of New Orleans, has (in 1857) drawn the attention of his countrymen to the subject. His estimate may be somewhat overdrawn, as such estimates frequently are; but the figures presented are certainly worthy of notice. The average cotton crop of the United States may be roughly given at 3,000,000 bales of 400 lbs. each, or 1,200,000,000 lbs. of ginned cotton. To each pound of fibre there are 3 lbs. of seed, making 3,600,000,000 lbs. of seed in all. Of this enormous quantity, 1,800,000,000 lbs. are retained for re-sowing, including waste. The remaining 1,800,000,000 lbs. are available for yielding oil and oil-cake. It is found that 100 lbs. of seed will yield 2 gallons of this oil, worth 4*s.* per gallon at New Orleans and 6*s.* at New York. After the pressure there will result 48 lbs. of oil-cake, equal in quality to that of linseed. There will furthermore remain about 6½ lbs. of oleaginous refuse available as soap-stuff, capable, when combined with very cheap alkali, of making 20 lbs. of useful soap. Summing up these items, they present the following money values: 36,000,000 gallons of cotton-seed oil at (say) 75 cents (3*s.* 2*d.*), 5,400,000*l.*; 864,000,000 lbs. of cotton-seed cake, at 1 cent (½*d.*), 1,728,000*l.*; and 106,000,000 lbs. of soap-stuff, at 3 cents (1½*d.*), 636,000*l.*; making a total of 7,764,000*l.* The bark-fibre is another prospective source of profit, the value of which remains to be determined. It has not yet been shown whether the oil is most likely to be useful as a salad oil, a fuel for lamps, a material for soap, an oil for leather-dressing, or a lubricator for machinery; but all these matters would speedily be settled if the oil became a regular marketable commodity. The oil-cake maintains a good place as a cattle-food, seeing that it contains from 9 to 16 per cent. of oil and 25 to 30 per cent. of albuminous compound.

We are now in a position to glance at the several cotton-growing countries, and to ascertain how much cotton they grow annually, what proportion of it is sold for manufacture in Great Britain, and what are the chances for an increased supply.

United States Cotton.—It is a remarkable fact that, while the production of this article has increased at a great rate in America, it has diminished in many other countries. This result has been attributed to various causes; among which may be mentioned, the good quality of American cotton, the low price of land there, and the great improvements that have been made in cleaning the cotton from its seed by means of Whitney's saw-gin, introduced in 1793. It is evident, however, that the greater part of these advantages might have been shared by many other countries in which the soil and climate are equally favourable for this branch of husbandry; and it will probably be more in agreement with the fact if we attribute the success of the American planters to their greater intelligence and industry, seconded by the commercial enterprise by which their country is characterised. Land fresh brought under cultivation in the United States will yield double the produce obtainable in the older states. One able-bodied labourer is sufficient for each eight acres of land, if assisted in the lighter part of the work by the aged and infirm, and the young people who belong to their families; the whole will, at the same time, be able to cultivate from five to eight acres of provision ground. The proportion of able-bodied labourers in each 100 of the entire working population of the cotton-growing districts in America, was estimated a few years ago at 32; the proportion of young persons not yet arrived at their full strength, and of elderly people still capable of some degree of labour, 25; the remaining 43 being composed of children under 14 years of age, and superannuated persons, none of whom are capable of any but very light work, such as weeding and picking the cotton. There is reason to believe, however, that these ratios vary at different times. It was estimated in 1836, that the whole quantity of land cultivated for cotton in the United States was two millions of acres; that the capital employed for the purpose was 800,000,000 or 900,000,000 dollars; and that the whole number of persons engaged in field labour, picking, and otherwise assisting in the cultivation of cotton, and raising their own provisions, was about 680,000. If to these were added the aged, the infirm, and the very young children composing the families of the labourers, besides overseers, owners, and their respective families dependent on the cotton crop, it was supposed that a million of persons were at that time engaged in the growing of cotton in the United States. Of later estimates we shall speak presently.

The extension of the cultivation in the United States is noteworthy. In the year 1786 no part of our supply was obtained from that country; indeed it was not until the year 1800 that the amount thence obtained became otherwise than insignificant. During the present century the advance has been quite unprecedented. In the eight years 1850 to 1857, both inclusive, the produce rose to millions of *bales* annually. To appreciate the full force of these numbers, it may be well to notice that the weight of an average bale of United States cotton varied in those years from 418 lbs. to 445 lbs., giving a mean of about 430 lbs.* The total produce at the following periods, with the portion of it which was exported from the United States to Great Britain and other countries, was (in round numbers), as follows:

	Total Produce.	Exported.
	Bales.	Bales.
1850	2,204,000	1,589,000
1854	3,035,000	2,318,000
1857	3,057,000	2,251,000

The difference between the total produce and the quantity exported represents pretty nearly the quantity worked up in the cotton mills of the United States. Applying the mean of 430 lbs. per bale, we shall find that on an average of the eight years, 1850–1857, the United States grew 2,960,000 bales, or 1,272,000,000 lbs. of cotton annually, of which 2,290,000 bales or 985,000,000 lbs. were sold to other countries.

The prices of United States cotton have varied considerably. In the year 1806 they ranged from 15*d.* to 24*d.* per lb.; in 1820, from 11*d.* to 17*d.*; in 1830, from 7*d.* to 9*d.* In 1845 the quality called "middling bowed" was 4¾*d.*; and in 1848 it was 4¼*d.* Taking all the qualities together, the average price varied, in the eight years from 1850 to 1857, at New York, from 4½*d.* to 12¾*d.* per lb., and the aggregate yearly values varied, in round numbers, from 21,700,000*l.* to 36,000,000*l.*, which was the value in 1857. When the price at Liverpool is 4¼*d.* per lb., it is considered that this is made up thus: 3*d.* for all expenses and profit of growing, and 1¼*d.* for further expenses till warehoused at Liverpool.

In 1857 the cotton manufacturers of Great Britain became very uneasy at their prospects of a supply of raw material. Their dependence on the United States was rendered every day more and more evident. Deficient crops and increasing demand drove up the price from 8·74 cents in 1855 to 12·75 cents in 1857. The American planters actually received most money in the year when the crop was smallest—showing how much there was in the trade partaking of the nature of a monopoly: a monopoly brought about, however, by our exclusive or protecting legislation. The English demand began to overtake the American supply about the year 1845; and ever since that date the state of the cotton crops in the United States has been a subject of yearly anxiety to the Lancashire manufacturers. What foundation there may be for hopes in other quarters, will be seen in the third article of this series; but the pressing question with manufacturers at present is—Can the United States produce be so increased in quantity as to be lessened in price? The chief cotton States are Louisiana, Alabama, South Carolina, and Georgia; these produce five-sixths of the total quantity. It may be well to give, for two recent years, the actual quantities in the eight cotton-producing States:—

	1856.	1857.
	Bales.	Bales.
Louisiana	1,661,433	1,435,000
Alabama	675,738	403,177
South Carolina	495,976	397,331
Georgia	389,445	322,111
Florida	144,404	136,344
Texas	116,078	87,882
North Carolina	26,098	27,147
Virginia	20,458	23,773

Some of the planters, believing England to be wholly at their mercy, advise a restriction rather than an extension of growth, in order that prices may be driven up still higher and higher. The merchants of New York, New Orleans, and the other shipping ports, however, more interested in the quantity of cotton to be shipped than in the price per pound, are making speculative estimates concerning the probable and possible in the cotton culture. Some computers, glancing at the capabilities of various parts of the United States, assert that there are 39 millions of acres of land fitted for growing cotton; that these would require 5 millions of slaves to tend them; and that the produce might be 8000 million pounds of cotton annually—many times the quantity at present worked in all the mills in the world. Hence there has been a sort of special pleading, to the effect that if Christendom would silently acquiesce in a renewal of the slave trade, there might be such an influx of slaves in the United States, and such an increased area of ground laid down in cotton, as to insure a lessening of price to English manufacturers. There are, on the other hand, many reasons for thinking that slave labour is really more costly than free labour; and that we ought to look rather to an increased supply of cotton from the East Indies and elsewhere, than to an extension of slave-raised produce in the United States. It would indeed be grievous if the hateful institution of slavery should be encouraged by the demand of England for raw cotton. There are agencies now at work which encourage a hope that such an evil may be averted.

South American Cotton.—The remaining portion of the American continent, as cotton growing districts, need not engage any lengthened attention.

The immense empire of Brazil does not occupy the rank which is due to it as a cotton-producing country. The total produce in sixteen years only varied from 19,000,000 lbs. to 35,000,000 lbs.; 1847 giving the smallest quantity, and 1850 the largest. The average may be about 25,000,000 lbs. This stagnant condition has been attributed to five causes: the abolition of the external slave trade, the dearness of labour, the ravages of insects, the peculiarities of climate, and the inaccessibility of the interior. Writers in the United States, especially those in the slave-holding interest, endeavour to show that all these difficulties must continue to prevent Brazil from being a flourishing cotton-growing country. There are other parties, however, who advocate the construction of a railway from Bahia into the interior, to a large district said to be eminently fitted for the culture. The Brazilian cotton is of good quality; and there certainly seems to be no sufficient reason for a continuance of the present apathy.

The other regions of South America need scarcely be named in connection with this subject. The coast districts of Peru and Chili have been found suitable for cotton cultivation; but the state of industrial enterprise has not hitherto been such as to lead to any considerable production.

West India Cotton.—It has already been stated that England relied upon the West Indies mainly for cotton, at a time when scarcely any was grown in the United States. In 1786 one-third of the English consumption was brought from the British West Indies, one-third from the foreign West Indies, one-quarter from Brazil, and the small remainder from the Levant. The British West Indian portion rose a little during the remaining years of the century; but from 1801 till the present time there has been a signal falling off. The yearly average quantity has gradually decreased from 34,000 bales in the five years, 1806-10, to 11,000 bales in the seven years, 1851-57. These quantities are nearly equivalent to the *total* production; seeing that nearly all the British West India cotton has been brought to Great Britain. The diminution has been attributed to several causes: the withering results of "protection," the maladministration of colonial affairs, supineness on the part of the colonists, and the scarcity of labourers since the abolition of slavery. The last is believed to be the more immediate cause of the backwardness of the culture at the present day. The free negroes will not work hard; as a class they prefer easy labour and small wages. The other labourers are Creoles, Coolies, and Portuguese. The planters are now urgently soliciting the British government for permission to import labourers from Africa, India, and China; but so strong is the apprehension of a revival of the slave-trade, as a consequence of this permission, that a disinclination at present exists to grant the necessary facilities. Demerara declares that she could increase her produce of cotton immensely, if the immigration of free labourers were allowed. Many planters strongly assert that free labour is in the end cheaper than slave labour. Lord Brougham, at the annual meeting of the British and Foreign Anti-Slavery Society, in May, 1858, said: "I find

---

* It is necessary to bear in mind the singular variations in the weight of bales of cotton; otherwise the comparison between the produce of different years and different countries will lead to fallacious results. Some cotton-growing countries uniformly employ larger bales than others; while nearly all have exhibited a gradual increase in weight, possibly due to closer and more perfect packing. The bales of United States cotton have gradually increased from about 215 lbs. to an average of 430 lbs. during the present century. During the last eight years (1851–1858) the average weights of bales have ranged as follow:—

United States'[†] cotton	430 lb.	per bale
Egyptian	384	"
East Indies	276	"
West Indies	204	"
Brazilian	181	"

[†] In view of the great preponderance of United States cotton, it is considered that *all* the cotton used in Great Britain may be now (1859) estimated at an average of 400 lb. per bale.

that Mr. Governor Hinckes, writing from Barbadoes in the present year, says that there is an estate which, during the times of slavery, was worked by 230 slaves, and which was sold for 15,000*l.* Since emancipation it has been worked by 60 free labourers and 30 children; it has produced three times the quantity of sugar which it formerly did; and it was sold last year for 30,000*l.*" It is true that this relates to a sugar-plantation; but there is apparently nothing to prevent it being equally applicable to one of cotton.

The foreign West Indies do not call for much remark. Their cotton produce is comparatively insignificant.

East India Cotton.—We now come to the country which, next to the United States, attracts most attention on the part of cotton manufacturers in this country. To India they look for a relief from the commercial shackles which bind them to the United States.

Not only did the natives of India cultivate cotton in times when no such material was as at all known in England; but the amount of produce was and still is really immense. They use woven cottons, not only for clothing, but for beds, cushions, awnings, draperies, hangings, carpets, screens, curtains, tents, ropes, and numerous other articles. It is utterly impossible to say how much is grown altogether, and therefore the estimates become very wide. Dr. White, in 1848, carried it up to 3000 million lbs. annually; but Mr. Ellison, in 1858, brought it down to the more sober level of 1800 million lbs. As even the smaller of these two estimates greatly exceeds the total quantity of all kinds imported into Great Britain, the practical question arises,—Why is there not more East India cotton brought to England? The quantity has certainly largely increased, but still it bears no reasonable ratio to the increase in the United States. In 1857 it reached 250 million lbs., but in 1858 it fell to 133 millions, the decrease being due almost wholly to the disturbance occasioned by the mutiny. Even the highest of these quantities is a very small per-centage of the whole cotton produce in India. It pays to export cotton from India to China; why should it not pay still better to send it to a country where it is so urgently needed as in England? Between 1850 and 1857, the price of East India cotton at Liverpool varied from 3⅛*d.* to 5⅜*d.* per lb. At a time when the price ranged from 3⅛*d.* to 5⅛*d.*, that of United States "uplands," of similar general quality, ranged from 4¾*d.* to 7¼*d.* The reason for this difference was, that the East India cotton was so dirty that 16 oz. of fibre would only yield 12 oz. of yarn; whereas an equal weight of "upland" would yield 13¼ oz. of yarn. The most recent estimate of cotton supply in India is perhaps that which Dr. Forbes Watson communicated to the Society of Arts, in March, 1859: "There is reason to believe that from time immemorial the cotton plant has been grown in all parts of India, and has always afforded suitable covering for the people of that country; not only does it serve for clothing, but it answers all the several purposes for which flax, wool, hemp, and hair are employed in this country. It may be, indeed, impossible to state the exact quantity per annum thus consumed; it has been variously estimated at from 5 lb. to 20 lb. per head for the whole population. If we assume 12 lb. as likely to be near the mark, we shall find that the present population of India, calculated at 180,000,000, requires annually 2,160,000,000 lb.; and if we further adopt Dr. Royle's average of 100 lb. as the yield of native cotton per acre, we shall find that there cannot be less than 21,600,000 acres under cotton culture, exclusive of that which supplies the present export of raw cotton. These on an average of the last three years amounted to 272,000,000 lb. (including the cotton sent to China and all other places as well as to Britain); and this again divided by 100, will add about 2,700,000 acres to the former quantity. The total quantity of cotton grown in India, according to the above calculation, will consequently amount to upwards of 2,432,000,000 lb., and demand for its culture certainly not less than 24,000,000 acres."

In seeking for the causes of the limited supply to England, and of the bad reputation of East India cotton, with a view to the adoption of remedial measures, the best authorities have drawn attention to five circumstances, all of them very important. We will present the reasonings thereon in a condensed form. 1. *Careless Cultivation.* The cotton-growers of India are very poor and very ignorant. They have no capital to rest upon; no English manufacturers at hand to incite them; no good apparatus for cleaning and pressing cotton; no protection from the roguery and oppression of the native dealers, to whom they sell. Dr. Royle recommended, as a wholesome stimulus, the settlement in the cotton-districts of Europeans, or their properly instructed agents. The duty of these persons would be, to encourage the natives to grow their cotton with more care, unmixed with other and injurious crops; to teach how to pick it as cleanly as possible off the boughs; and to separate the seeds by the best machines obtainable. Or the agent might be instructed to purchase the seed cotton (in the rough state, just as picked from the bush), and clean it himself on the spot. Dr. Royle, a most competent authority, urged that a small amount of money spent in this way would be immensely beneficial, both to India and to England. 2. *Deficient Irrigation.* In the East Indies there is seldom more than 100 lbs. of cotton produced per acre, against 400 lbs. or upwards in the United States. This deficiency is mainly due to imperfect irrigation. The climate exhibits many rapid extremes of heat and cold, wet and dry; and there are few of the cotton-fields which do not suffer, either from too much or too little moisture. What is urgently needed is, draining of the wet land, and especially irrigation of the dry. There is a general opinion that the Indian government would find it profitable to execute works of irrigation, since it would greatly increase the revenue derived from land-tax—the principal fiscal resource in India. Much has been done in this direction within the last few years; and much more would have been done but for the recent excessive demands of the war-department, which have exhausted the exchequer. This interruption of useful public works is much to be regretted; for wherever irrigation works have been constructed the benefit has been great, both financially and morally. A table compiled by Colonel Cotton enumerated thirty-nine different works of irrigation which have been constructed in the Madras presidency during fourteen years, at an expense of 54,000*l.*; which have resulted in a total increase of revenue (after deducting disbursements for repairs) to the amount of 70 per cent. per annum on the original outlay. The Jumna and Ganges irrigation canals have in like manner been eminently useful. 3. *Want of Roads.* The mode of bringing the bales of cotton from the fields to the shipping ports is most tedious and expensive, owing to the deficiency in good roads and means of conveyance. Ox teams and clumsy vehicles are, at present, almost the only available means. General Briggs, in evidence given before the Cotton Supply Committee in 1848, said: "In the absence of a defined and good road, a drove of several hundred head of cattle requires to be constantly watched, and prevented from straying on the march; and this leads to the necessity of travelling by day in hot weather, when the thermometer is seldom less than 100° Fahr. These droves are seldom so few as 100, and often exceed 1000. Every morning after breakfast each ox has to be loaded, and before this operation is over the sun is already high above the horizon. The cattle have then to proceed at the slow rate of two miles an hour, and seldom perform a journey of more than eight or nine miles a day. The herd generally halts one day in seven. If the caravan is overtaken by rain, the cotton, becoming saturated with moisture, is so heavy as to prevent its transport on the cattle; and the roads, if lying through the [wet] ground, are so deep that men even sink above their ankles at every step, and cattle to their knees. It may be easily supposed that under such a calamity, the merchant and the carrier are both ruined." The mode of shipping cotton at Baroach will illustrate one stage in this very clumsy arrangement. The bales are first rolled down to the verge of the muddy shore, into which they sometimes plunge; each bale is then lifted on the shoulders of six men, who stagger up to their knees, or even up to the waist, in mud, to the boat which is to convey the cotton to the ship. Great results will follow from the present construction of main trunk lines of railway through the heart of India; but there must be good roads made from these railways to the sea, and good quays at the shipping ports, before the difficulties of transit can be overcome. 4. *Tenure of Land.* Enterprising and monied cotton-growers are deterred from speculating in India by the unsatisfactory nature of the land-tenure. The government is the sole owner of the soil. Estates are held conventionally, by a sort of tenant right. The cultivators, who we have said are poor, have little inducement to extend their operations, because they fear that any surplus would go to the government in the shape of increased land-tax; the fear may not be well-founded, but it certainly prevails to a large extent among the natives. What seems to be wanted is, the introduction of freehold, copyhold, or leasehold tenures, to give the cultivator both a pride and a profit in an improved mode of husbandry. Mr. Ellison * remarks: "If the East India Company would dispose of their lands, either in perpetuity or for long periods of time, there is no doubt that not only native but English capitalists would be found in plenty to invest their money in the same. The effect of such a proceeding would be, not only an opening up of the resources of India, but it would also cause a portion of the tide of emigration to be turned in that direction. British energy and enterprise would then take the place of Indian indifference and lassitude, and soon double the present extent of our commerce with Hindostan." 5. *Apathy of Manufacturers.* So long as the English spinners and weavers can obtain fair profits for their cotton goods, they care not whence the supply comes; and thus it has been found extremely difficult to bring them to act upon any one common plan to improve and extend the sources of supply. When, on the other hand, profits are low, the manufacturers become alarmed, and blame the government, with or without reason. Until the year 1829, the supply kept ahead of the consumption. In the next six years the demand exceeded the supply, lessening the stock in hand at Liverpool from forty weeks' consumption in 1829, to fifteen weeks' consumption in 1835. After this, owing to the encouragement afforded by high prices, the supply gained on the demand for ten years, bringing the reserve stock in 1845 up to thirty-nine weeks' consumption. Then consumption began again to get ahead of supply, and the Lancashire manufacturers were uneasy. They appealed to the East India Company, urging them to encourage the cotton cultivation in India. Sir James Hogg, on the part of the company, recapitulated what had been done, and recommended the manufacturers to send out a competent agent to the East Indies, to examine into the whole question, and see how far and in what way improvements might best be wrought.

---

* 'Handbook of the Cotton Trade,' 1858—the most recent and valuable work on this subject, compiled from authentic official documents, English and American. We have much pleasure in acknowledging our obligations to Mr. Ellison's volume.

What was done in this matter, we shall see presently, in connection with the Cotton Supply Association.

Egyptian Cotton.—Until about thirty years ago, Egypt produced cotton only in small quantities; but the introduction of good seed and improved methods of culture by the energetic pacha, Mohamet Ali, led to a marked advance. England first imported cotton from Egypt in 1823. In 1855, Mr. Clegg, from inquiries made at Alexandria, computed that there were 60,000,000 lbs. of cotton grown annually. England takes far more than half the produce, the next best customers being France and Austria. The small excess above the quantities so exported is worked up in the cotton mills of Egypt.

North African Cotton.—It was in the year 1850 that the French government first began to direct attention to the cultivation of cotton in Algeria. A portion of the coast was found to possess a soil and climate fitted for this plant. In 1855 there were 150 exhibitors of Algerian cotton at the Paris Industrial Exposition. In that year, about 9000 acres of land were under cotton culture. In 1856 and 1857, the produce fell off in quantity, supposed to be owing to a rush of cultivators into the trade who had neither the requisite capital nor skill. There is, however, no reason to doubt that a steady increase of produce will be exhibited in future years, even though it may never reach any important amount. Along the further portion of the African coast, towards the Atlantic, there is not at present cotton grown in a regular way for the European market; but the English manufacturers are endeavouring to encourage it, by sending good seed, and making known better modes of culture; and the sovereigns of Morocco and Tunis seem well disposed to second these endeavours.

West African Cotton.—Considering the nature of the climate and the abundance of labour at the west, or rather north-west, coast of Africa, there is every reason to think that cotton might be extensively grown in that region. Mr. Clegg, on the part of the Lancashire manufacturers, in conjunction with the Church Missionary Society, has brought this subject under the notice of the authorities at Sierra Leone, Lagos, Fernando Po, Liberia, and the interior. In the year 1852 there were 1810 lbs. of cotton brought to Liverpool from that region; it gradually rose, until the first four months of 1858 exhibited an import of 96,000 lbs. Mr. Clegg's own account of his operations, communicated to the Society of Arts in December, 1858, is full of interest: "Some ten years ago, seeing the importance of the subject, he thought he would, as an individual, see if he could not get cotton from somewhere else than America. He turned his attention to Africa; and he asked the Church Missionary Society, of which he was a member, to select for him suitable agents, to whom he could entrust money for the purchase of cotton from the African natives. He made arrangements always to have money on the spot, in the hands of the agents; and his instructions were, that they should purchase the cotton of the natives in however small parcels it might be brought to them; if only half a pound had been plucked from the plants, they were to buy it. The consequence was, that in a short time the women brought small quantities of cotton to the stations: this was communicated to their neighbours; and in a little while afterwards seed was planted, and the cotton growth became more and more plentiful. He sent out a number of cotton gins, which the natives soon learned to use. He also erected a store, and placed a large number of gins in it. The natives brought the cotton in pods and in seed, and they learned to clean it; and after using a gin sufficiently long to pay the expense of it, they shouldered the implement and carried it off as their own property, to be used hereafter in dressing the cotton they brought for sale. He had introduced three young African natives into his mill at Manchester, where they had been taught the use of machinery generally; and they had been sent back to their own country, to carry out the preparation of cotton upon a larger scale." Mr. Clegg estimates that West African cotton can be sold at Liverpool for 4¼*d.* per lb., made up thus:—

	d.
4 lb. of cotton in the seed, at ½*d.*	2
Cleaning it into 1 lb. of good fibre	¼
Packing and canvas	½
Carriage to port and shipping	¼
Freight to England	1
Charges at Liverpool	¼
	4¼

If the cotton were of fairly good quality, and moderately clean, it would meet with eager purchasers at anything near this price.

South African Cotton.—Whether the region around the Cape of Good Hope could produce cotton of a quality and price that would compete with that of America in the English market, is a problem not yet answered; there is not at present an organisation sufficient for ensuring a due and steady supply of labour. Attention is, however, at present directed to a part of Africa north of the Cape, scarcely known to Europe until Dr. Livingstone visited it. This skilful and energetic traveller, in passing through the country of Angola, saw the native women spinning cotton with spindle and distaff. "The cotton was brought to the market for sale, and I bought a pound for a penny; this was the price demanded, and probably double what they ask from each other. We saw cotton growing luxuriantly all around the market-place from seed dropped accidentally. This is seen also about the native huts; and so far as I could learn, it was the American cotton so influenced as to be perennial." He found an abundance of willing labourers; but no roads from the cotton-fields to the sea-coast. "I found the people were anxious to engage in commerce with us; but they had no roads, nor pathways down to the coast; and although 100,000*l.* worth was annually exported in ivory, bees'-wax, and palm-oil, yet every ounce thus procured was taken down to the coast on the heads and shoulders of men." M. Canto, Portuguese commandant of Gelanjo Alto, on one occasion said to Livingstone, "If I had possession of a few hundred pounds, I would create a complete revolution in the commerce of this country; I would purchase all the cotton now produced, and certainly next year they would produce much more; and then the third year I could make myself rich with a few hundred pounds." When Dr. Livingstone returned to Africa in 1858, he took with him a few bushels of very fine cotton seed, to encourage the natives to grow cotton fitted for the English market, hoping that roads and other facilities would gradually be obtained. In a debate in the House of Commons on the Slave Trade, on July 12th, 1858, Lord Palmerston expressed himself thus strongly: "I venture to say that your commerce with the (south) western coast of Africa in the article of cotton will, in a few years, prove to be far more valuable than that of any other portion of the world—the United States alone excepted."

Miscellaneous Cotton Districts.—All the remaining cotton-growing districts may be passed over briefly. *Asiatic Turkey* used formerly to be a great source of supply for England; but the portion furnished has now become very small—partly because the inhabitants of Asia Minor and Syria have introduced the cotton manufactures among themselves, and partly because the portion exported goes to France rather than to England. It is believed that, so far as natural capabilities are concerned, the produce in Western Asia might be immense; but to develope this produce would require irrigation, good seed, capital, energy, and skill. *Spain* and *Italy* grow a little cotton, but it is too little to need attention here. *Australia* has been examined in certain places, with a view to ascertain whether the soil and climate are suited for cotton culture. There is a district, measuring about 300 miles by 100, near Moreton Bay, which is believed to possess many of the requisite qualities; but the scarcity of cheap labour is at present an insuperable difficulty.

To what extent the several countries of the world *consume* the cotton thus grown, is a subject treated in a separate article [COTTON TRADE AND CONSUMPTION]; we have here purposely confined our attention almost exclusively to growth and supply.

COTTON MANUFACTURE. We now arrive at the second of the three divisions into which it has been deemed desirable to group the information concerning cotton; namely, the manufacturing processes, in their history and their practice.

The use of cotton as a material for the production of woven fabrics, was known in India and China for many centuries before its introduction into Europe. The earliest mention of cotton by the Greek writers is by Herodotus (iii. 106) in his brief notice of the usages of the Indi: he calls it (iii. 47) by the significant name of tree-wool (*εἴριον ἀπὸ ξύλου*), apparently not being acquainted with the native name. In the reign of Amasis, B.C. 563–525, cotton was known in Egypt; but it must have been imported, for there is no reason for supposing it was then grown in Egypt. Cotton cloths were, according to Arrian, among the articles which the Romans received from India; and there is no doubt the manufacture had been carried on in many parts of Asia, long before any extant notice of that quarter of the world being visited by Europeans. The perfection to which the weaving of cotton had then been brought by the natives of many parts of India, notwithstanding their rude and imperfect implements, attests at once their patience and ingenuity. In China, this manufacture is supposed not to have existed at all before the beginning of the sixth century of the Christian era. The cotton plant was indeed known in that country at a much earlier period, but continued till then to be cultivated only as a garden shrub, and was not indeed propagated on a large scale until the eleventh century; at the present time nearly all the inhabitants of that populous empire are clothed in cotton cloths of home manufacture, made from cotton brought in part from India, but mostly of home growth.

Before the discovery of the passage to India round the Cape of Good Hope, cotton wool is said to have been spun and woven in some of the Italian states, the traders of which were the channels through which the cotton fabrics of India were distributed to the different countries of Europe. Becoming thus acquainted with these goods, and having near at hand the raw material of which they were formed, it was natural that they should apply to the production of similar goods the manufacturing skill they had long possessed.

Baines has shown ('History of the Cotton Manufacture,') that the cotton plant was extensively cultivated, and its produce manufactured, by the Mohammedan possessors of Spain in the tenth century. This branch of industry flourished long in that country. In the thirteenth century the cotton manufacturers formed one of the incorporated companies of Barcelona, in which city two streets received names which point them out as the quarter in which the manufacturers resided. The cloths made were mostly of coarse texture, and a considerable quantity was used as sail-cloth. The name *fustians*, from the Spanish word *fuste*, signifying "substance," was borrowed from the Spanish weavers, and is still used to denote a strong fabric made of cotton. The intercourse between the Mohammedan possessors of Spain and the Christian inhabitants of other European countries was so small, owing to religious prejudice, that the arts which long flourished among the former, did not extend themselves to the latter; the traffic of Andalusia was all carried on with Africa and the East.

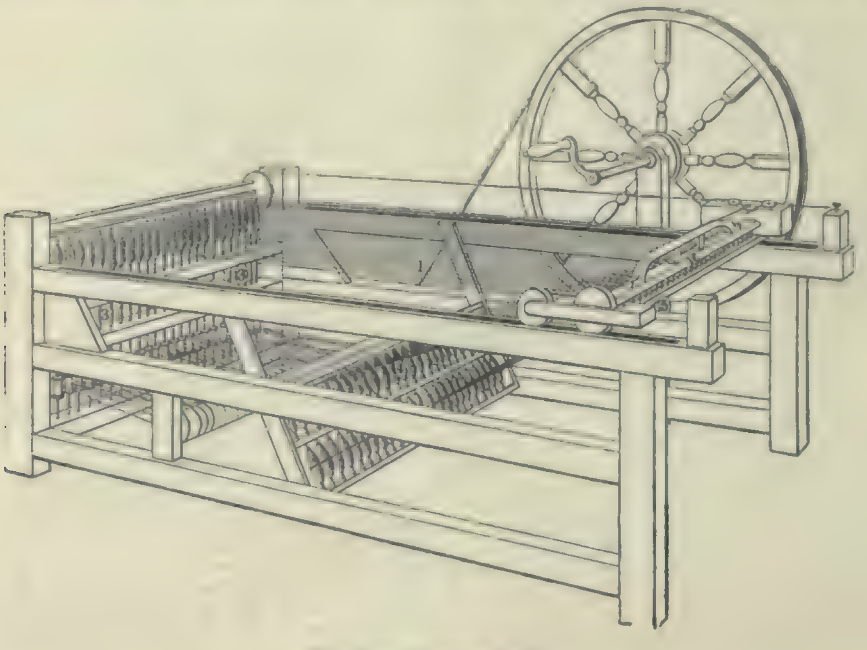
From Italy the cotton manufacture made its way to the Netherlands, and about the end of the sixteenth or the beginning of the seventeenth century was brought thence to England by protestant refugees. Lewis Roberts, in 'The Treasure of Traffic,' published in 1641, makes the earliest mention extant of the manufacture in England. He says, "The town of Manchester buys cotton wool from London that comes from Cyprus and Smyrna, and works the same into fustians, vermilions, and dimities."

There is abundant evidence to show that in the beginning of the sixteenth century, and probably before that time, cotton was cultivated and converted into clothing in most of the countries occupying the southern shores of the Mediterranean. The European conquerors of Mexico in their first invasion of that country found in use native manufactures of cotton, both unmixed and mixed with the fine hair of rabbits and hares. Some of these fabrics were sent by Cortes to Spain as presents to the Emperor Charles V. Cotton was cultivated and manufactured at an equally early period by different nations on the coast of Guinea, and it is stated by Macpherson in his 'Annals of Commerce,' that cotton cloths were imported into London in 1590, from the Bight of Benin.

It would be difficult to trace the introduction of the cotton manufacture in the different countries of Europe where it is now established but some notice of its recent progress and present state therein will be found in the next following article.

In England, previous to the introduction of the inventions of Arkwright, this manufacture was of small importance, as is evident from the quantities of the raw material then brought into the country. Arkwright's first patent for the mode of spinning by rollers was taken out in 1769; and between the years 1776 and 1780 the average annual consumption barely reached seven millions of pounds. The system under which this manufacture was long carried on was very different from that which is now pursued. It was the custom for the weavers who were dispersed in cottages throughout the district to purchase the material with which they worked, and having converted it into cloths, to carry their wares to market and sell them on their own account to the dealers; but about 1760, the merchants of Manchester began to employ the weavers—furnishing them with yarn for warp, and with raw cotton to be spun by the weaver's family into weft, and paying a fixed price for the labour bestowed in weaving.

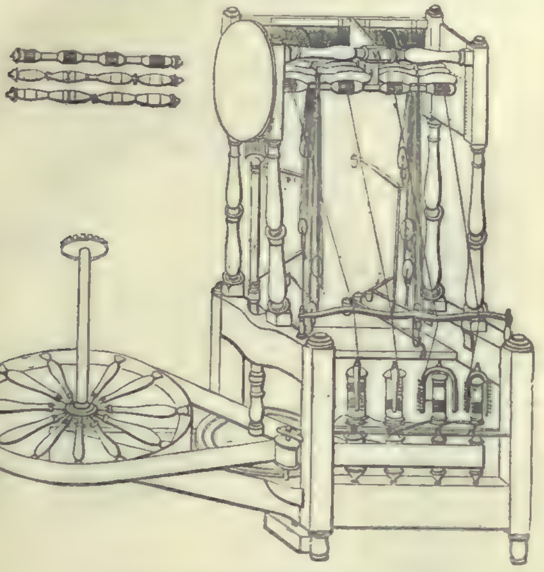
The application of machinery to the preparation and spinning of raw cotton for weft preceded by some years the inventions of Arkwright. In the year 1760, or soon after, a carding engine not very different from that now used was contrived by James Hargreaves, an illiterate weaver, residing near Church in Lancashire; and in 1767 the *spinning-jenny* was invented by the same person. This machine, as at first formed, contained eight spindles, which were made to revolve by means of bands from a horizontal wheel. Subsequent improvements increased the power of the spinning-jenny to eighty spindles, and the wheel was placed vertically, as in the annexed cut:—where the rovings (1), clasped and drawn by the frame (5), are transferred in an attenuated state from the spindles (3) to (4). The saving of labour which it thus occasioned produced considerable alarm among those persons who had employed the old mode of spinning; and a party of them broke into Hargreaves' house and destroyed his machine. The great advantage of the invention was so apparent, however, that it was soon again brought into use, and nearly superseded the employment of the old spinning-wheel. A second rising then took place of the persons whose labour was thus superseded by it; they went through the country destroying, wherever they could find them, both carding and spinning machines, by which means the manufacture was for a time driven away from Lancashire to Nottingham.



[Hargreaves' Spinning Jenny.]

The cotton-yarn produced both by the common spinning wheel and the spinning-jenny, though suitable for weft or cross-threads, could not be made sufficiently strong to be used as warp or long-threads; and, therefore, linen-yarn was used for the last-named purpose. It was not until Arkwright's spinning frame was brought into successful operation that this disadvantage was overcome. Yarn spun with Hargreaves' jenny continued for some time to be used for weft. At first, the manufacturers of cloths composed of cotton only were subject to much annoyance from the determination of the revenue officers to charge them with double the duty paid upon calicoes woven with linen warp and printed for exportation; and also by prohibiting their use at home. With some difficulty an act of parliament was obtained for removing these obstacles to the development of the manufacture, which from that time was prosecuted with a great and continually accelerated rate of increase.

The earliest attempts at producing the finer cotton goods called *muslins* were made about the year 1780; but without much success, although India-spun yarn was substituted as weft for that produced by the spinning-jenny: the greatest degree of fineness to which yarn spun with Arkwright's frame had then been brought, was eighty hanks to the pound, and even this degree was not attainable by means of the jenny. This disadvantage was overcome by the invention of Samuel Crompton's machine, which came into general use about the year 1786, and which, partaking of the nature of both Hargreaves' and Arkwright's machines, was aptly called the *mule jenny*. By means of this piece of mechanism, yarns were produced of a much greater fineness than had before been attained. Crompton's invention was made several years before it could be openly used, because of its interference with the patented invention of Arkwright; but when this patent was annulled, the mule-jenny was brought rapidly and extensively into use. No less than 500,000 pieces of muslin were made at Bolton, Glasgow, and Paisley, in 1787, with yarn of British production.



[Arkwright's Original Spinning Frame.]

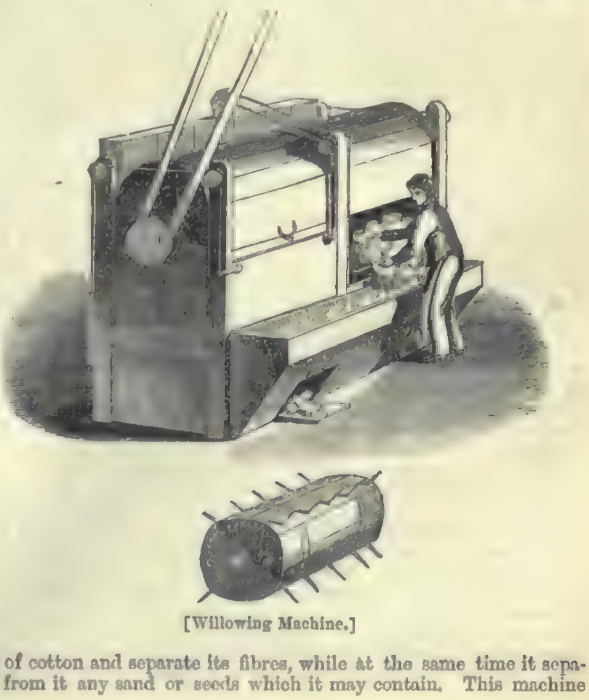
Crompton did not secure to himself the benefit of his invention by taking out a patent; he carried on a spinning and weaving business on a small scale at Bolton, and worked his mule-jenny with his own hands in an attic. In a brief memoir of Crompton, Mr. Kennedy has stated, that about 1802 he, in conjunction with Mr. Lee, set on foot a subscription which amounted to 500*l.*: and that with this fund Crompton was enabled to increase his manufacturing establishment, and to set up several looms for fancy work in Bolton. In 1812 Crompton made a survey of all the cotton manufacturing districts in the kingdom, and ascertained that the number of spindles then at work upon his principle amounted to between four and five millions. The kind friends already named assisted him in making an application to parliament for some reward; and the great merit of his invention having been established before a Committee of the House of Commons, he received a grant of 5000*l.*, which was paid to him in full without any deduction for fees or charges. This money was employed by Crompton in putting his sons into business; but they proved unsuccessful, and he was reduced to poverty. Mr. Kennedy again interfered in his behalf, and raised a second subscription, with the produce of which a life annuity of 63*l.* was purchased. Crompton lived only two years to enjoy this small provision. The first mule-jennies consisted of not more than thirty spindles each, but the number has been progressively increased, and they now frequently contain from 600 to 1000 spindles each, or even a still greater number. The next great improvement in the construction of this machine was effected by Messrs. Sharp, Roberts & Co., machinists of Manchester. Their machines, which are called *self-acting mules*, do not require the manual aid of a spinner, the only attendance necessary being that of children, called piecers, who join such threads as may be accidentally broken. Self-acting mules were contrived at different times by Mr. William Strutt of Derby, Mr. Kelly of Lanark, Mr. De Jongh of Warrington, and others; but none of these were brought successfully into use, owing, no doubt, in some measure, to the inferior skill of the machine makers of those days.

Another event which contributed to the rapid extension of the cotton manufacture, was the successful attempt to weave by means of machinery, made in 1785 by Dr. Cartwright, who secured the invention by patent. In a commercial point of view Dr. Cartwright did not draw any advantage from his power-loom; but in 1809 he obtained from parliament a grant of 10,000*l.* as a reward for his ingenuity. Mr. Monteith, of Pollokshaws, Glasgow, who fitted up 200 power-looms in 1801, was the first person who brought them to profitable use. A great obstacle to their success was presented by the necessity for the frequent stopping of the machine in order to dress the warp. This difficulty was removed in 1804 by the invention of a machine for dressing the whole of the warp before it is placed in the loom, which was made the subject of a patent by Mr. Radcliffe, the inventor. In the use of this machine the warp in its progress to the weaving beam is passed through a dressing of hot starch: it is then compressed between rollers to free it from the superfluous quantity of starch taken up; and afterwards, in order to dry it, the warp is drawn over a succession of cylinders heated by passing steam through them. By this means the weaver is relieved from the necessity of stopping from his weaving to dress the warp.

The machines and apparatus of recent introduction, connected with the cotton manufacture, almost countless as they are in number, are rather extensions and improvements of systems already known, than inventions partaking of the capital importance of those of Arkwright, Hargreaves, Crompton, Cartwright, Radcliffe, and Roberts. Instead of attempting the hopeless task of describing the various modern inventions, we shall proceed at once to a description of the processes in their ordinary routine. The cotton fibres have to be spun into yarn or thread before they can be woven into calico, fustian, muslin, or other textile material; and this spinning is the most important part of the whole operation. Nevertheless it can be effected, in a slow way, with few and rude implements. Among all the ancient mechanical arts there were few so simple as that of converting the downy filaments of the cotton plant into a continuous thread according to the methods generally used before the time of Hargreaves and Arkwright. The same primitive methods are still employed in eastern countries. There are, on the other hand, few processes for the performance of which the inventive powers of man have since that period been more taxed, in this country and during this age of invention, than for the cheap and perfect production of cotton twist and yarn. The use of the spindle and distaff was superseded in England by the spinning-wheel, in or soon after the reign of Henry VIII. The next improvements in this useful art were those of Hargreaves and Arkwright; which were followed by the whole train of novelties just adverted to.

One of the first processes in a cotton mill is that of mixing the fibres. Owing to the great variety generally found in the quality of different bags of cotton, which would otherwise occasion a corresponding difference in the quality of the yarn produced, the contents of several bags are mixed together in a heap. This is done by spreading out the contents of each bag in a horizontal layer of uniform thickness, the contents of the several bags forming separate layers and resting one upon the other, so that the number of layers corresponds to the number of bags. In making this heap, which is called a *bing* or *bunker*, the several layers are trampled or pressed together somewhat in the manner of building a hay-stack. The cotton of which the bing is composed is then torn down by a rake from top to bottom. It is evident that in its progress a portion of each horizontal layer will be brought away, and that thus, if the work be skilfully done, the contents of the different bags must be collected together in a mass of uniform quality. It is customary to mix in this manner different descriptions of raw cotton for the production of various qualities of yarn; and some skill on the part of the manufacturer is called for in order to produce a mass that will answer the intended purpose at the least possible cost. The practice of different spinners varies much in this respect, but it is considered proper as a general rule to mix together only such qualities as are similar in the length of their staple. The waste cotton produced in the previous operations of the mill is mixed in the bing in certain proportions for making the lower or coarser qualities of yarn. For the higher or finer numbers, and for twist which is used for warp, finer qualities of cotton are required than for low numbers or for weft. It may here be mentioned that in the technical language of the trade, 'high numbers,' meaning fine yarns, denote a great number of hanks to the pound; while 'low numbers,' meaning coarse yarns, denote a smaller number of hanks to the pound.

When the cotton has been mixed, the machine next employed is usually the *Scutching or Willowing Machine*. This is used to open the locks of cotton and separate its fibres, while at the same time it separates from it any sand or seeds which it may contain. This machine



[Willowing Machine.]

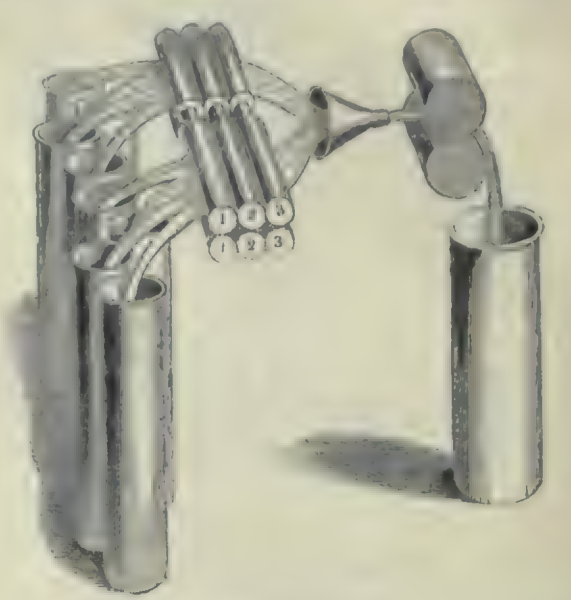
consists of feeding-rollers made of wood and placed at a short distance from each other; the cotton, while passing slowly between the rollers, is struck by a set of beaters made to revolve from 1000 to 2000 times in a minute. The cotton is passed through two such sets of rollers, and subjected to two sets of beaters. It is then taken to the *Spreading Machine*, the use of which is to spread a given weight of cleaned cotton into a given length and breadth, in order to its being presented of uniform thickness to the next process. The spreading machine is, however, not universally used; where the heavier quality of yarn is spun it answers sufficiently well, and effects an adequate saving of labour; but for fine yarns, where the greatest precision is required in order to produce regularity in the size of the yarn, machine-spreading does not answer so well as hand spreading. The cotton is weighed very accurately before it is put into the spreading-machine, and when perfectly spread is called a *feed*, the thickness of which will of course be regulated by the weight of cotton supplied to the machine. This operation is repeated continuously, so that an unbroken sheet of cotton passes through the machine and is wound on a wooden roller. In this form the cotton is called a *breaker lap*.

Up to this stage the fibres of the cotton cross each other in every direction. The *Carding Engine* then comes into requisition, to disentangle them, to draw them out, and to lay them parallel to each other. Properly speaking, this is the first operation of spinning—the previous processes being used only to open and clean the cotton. The card is a species of brush made of short wires passed through a sheet of leather and pointing all in one direction. In the early period of cotton-spinning in this country, these cards were nailed on small pieces of board with handles, and two of them were used together, one held in each hand. The first improvement made in this implement was effected about 1760, by James Hargreaves, the same ingenious man who, a few years later, invented the spinning-jenny. This improvement in the cards consisted in having one of them greatly increased in size, and fixed; this was called the stock, and the other was suspended by a cord working in a pulley, fixed to the roof of the work-shop; the effect of this arrangement was that two or more cards could be applied to the same stock. This modification was immediately followed by the greater improvement of *cylinder cards;* the father of the first Sir Robert Peel set up a machine of the kind at Blackburn in 1762, with the assistance of Hargreaves. The inventor of cylinder cards is not known with certainty; but Mr. Baines ascribes the invention to Lewis Paul, who took out a patent in 1748 for improvements in carding. The carding engine, which was the natural result of the invention of cylinder-cards, consists of a horizontal cylinder covered in its entire circumference with narrow fillet cards wound spirally round the cylinder, leaving an intervening space between the several spiral lines thus described. Over the cylinder is a concave frame, the interior surface of which is lined with cards, and the form of which corresponds to that of the cylinder. When the cylinder is made to revolve, the cards on it and on the frame act against each other, by which means the fibres of cotton are disentangled and properly arranged, as already mentioned. The cylinders, which are usually about 3 feet in diameter and 3 feet long, are made to revolve at the rate of 100 to 150 turns in a minute.

The cotton, in the form already described as a breaker lap, is led into the carding machine by a slow motion through feeding-rollers, little more than one inch in diameter. The fibres of the cotton are then immediately engaged by the wires of the main cylinder, and after being by their means properly arranged, are thrown off by its velocity to a second cylinder called a *doffer*.

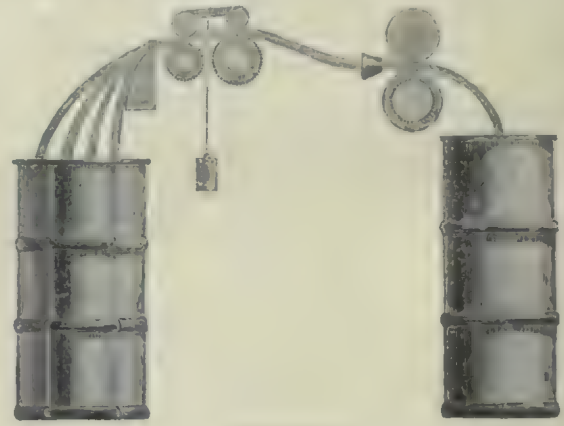
When cylinder-cards were first used, hand-cards were employed to take off the cotton. Various contrivances were at different times adopted for improving this part of the process; until at length Arkwright contrived for the purpose a plate of metal toothed at the edge like a comb, which, instead of revolving as the former contrivances had done, was, by means of a crank, made to move rapidly in a perpendicular direction, and with slight but reiterated strokes on the teeth of the cards detached the cotton from them in a uniform fleece. This fleece is made to undergo compression on its passage to a roller, from which it is delivered in the form of a thick but soft thread, called a *card-end*, or *sliver*, into a tin can. The duration of the carding process is made to depend upon the quality of the cotton under preparation; if the fibres are short and coarse, the carding should be quickly performed, not indeed by accelerating the speed of the cylinders, but by taking the cotton faster off the cards.

The next operation is called *drawing*, and the machine by means of which it is performed is called the *Drawing-frame*. The object of this drawing is to complete what has been begun by the carding engine, namely, the arranging of the fibres of cotton longitudinally, in a uniform and parallel direction, and to remedy all existing inequalities in the thickness of the sliver. The drawing-frame acts upon the same principle as Arkwright's spinning-frame, two or three sets of rollers being employed moving with unequal velocities. In its passage through the first pair (1, 1) the sliver is simply compressed; but being drawn through the second and third pairs (2, 2 and 3, 3) with gradually increasing velocities, it is necessarily drawn out in the same proportion. In repeating this operation, which is called *doubling*, two, three, or a greater number of the drawings are passed through each set of rollers; in the first they are made to coalesce, and in the second are again drawn out. These doubling and drawing processes are repeated very frequently, in order to correct every inequality in the thickness of the cord or sliver; they are of the utmost importance, and if ill or insufficiently performed, the yarn cannot prove of good quality.



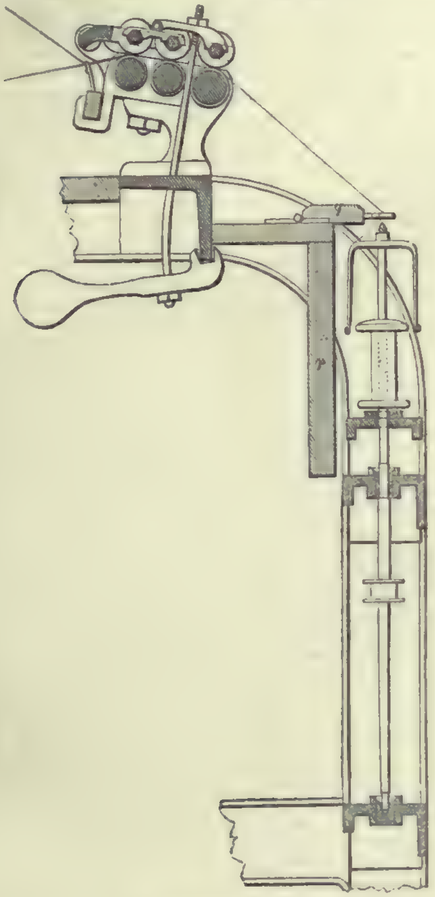
[Drawing Rollers and Cans.]

Roving, the next step in the process, is a continuation of the drawing, with this only difference—that the cord, now called a *rove* or *slub*, being so much reduced in thickness that it will not otherwise hold together, a slight twist is given to it by passing it into a metal can, which, while receiving it, is made to revolve with great velocity. The rove thus slightly twisted, is wound upon bobbins, and is then ready for the spinning-frame. About the year 1817, a machine called a *fly frame* was contrived for preparing rovings for inferior numbers of yarn. Instead of revolving cans, this frame is provided with a series of spindles, each of which is furnished with a flyer; the revolutions of this flyer give the requisite twist to the cord, which is delivered at once to the bobbin fitted loosely on the spindle. The *tube frame*, more recently introduced, is used for preparing yarns of all qualities. Instead of cans, this frame is provided with revolving horizontal cylinders; and by its means a much greater quantity of work can be done in a given time than with the fly frame; the rove which it produces has no twist, and is therefore very tender, and the quantity of waste which it occasions is greater than is otherwise experienced.



[Roving Cans.]

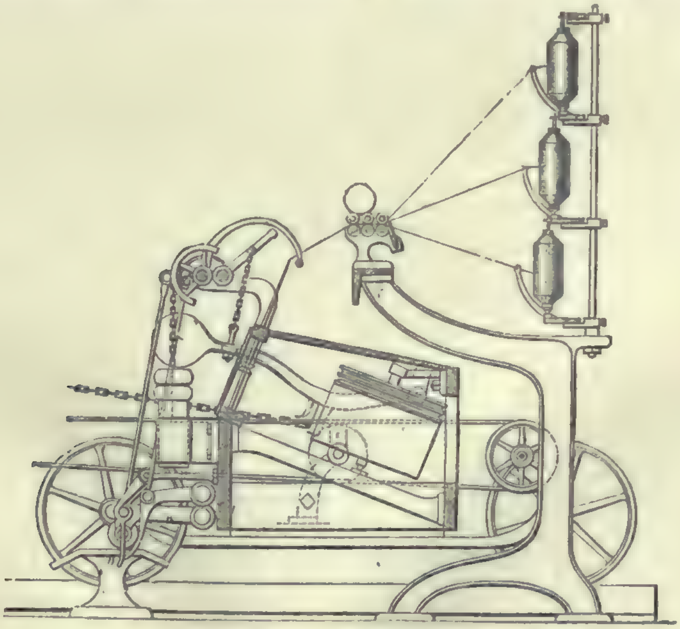
The important process of *Spinning* then comes for notice. The principle of Arkwright's original *Spinning frame* may be briefly described: There were two pairs of rollers; the first pair slowly revolving in contact; and the second pair, at a little distance, revolving with greater velocity. The lower roller of each pair was fluted longitudinally, and the upper one was covered with leather, by which means the two would have a sufficient hold upon the cotton passed between them. The cotton, when passed between the first pair of rollers, had the form of a thick but very soft cord, and was no further altered in its texture than by receiving a slight compression; but as the second pair of rollers moved with many times the velocity of the first, the cotton was drawn out many times smaller than when delivered from the first rollers.



[Throstle spinning.]

The yarn produced by its means received the name of *water-twist*, from the circumstance of the machinery being at first set in motion by water power. The *Throstle frame* is the same in principle as Arkwright's invention; but the movement of the parts is simplified, so that the speed of the machine is increased, and a greater number of spindles may be driven with an equal amount of power; it was introduced about the year 1810. The *Mule-jenny*, invented by Samuel Crompton, combines the essential principle of Arkwright's frame with the property of stretching possessed by Hargreave's jenny. By means of the mule-jenny, the roving is first drawn and then stretched. The effect of this improvement is to make the yarn finer, and of a more uniform tenuity. When delivered by the rollers, the thread is thicker in some parts than in others; these thicker parts, not being so effectually twisted as the smaller parts, are softer and yield more readily to the stretching power of the mule; and by this means the twist becomes more equable throughout the yarn. Throstle-spinning is seldom employed for higher numbers than forty to fifty hanks to the pound, because smaller yarn would not have strength to bear the drag of the bobbin; but in mule-spinning no bobbin is used, and the yarn is wound or built upon the spindles without subjecting it to any strain. The spindles in this machine are regularly arranged on a carriage, which when put in motion recedes from the rollers with a velocity somewhat greater than that at which the reduced rovings are delivered from them; during this time the yarn is receiving its twist by the rapid revolving of the spindles; when the rollers are made to cease giving out the rovings, the mule-jenny still continues to recede, but with a slower motion, and its spindles to revolve; and thus the stretching is effected. The distance which the spindles recede from the rollers while both are in action is called a *stretch;* this is usually about fifty-four or fifty-six inches: the space through which the mule moves greater than and during the giving out of the rollers, is called the *gaining* of the carriage; and the further space accomplished by the carriage after the rollers are stopped, is called the *second stretch;* during this latter part of their progress, the spindles are made to revolve much more rapidly than before, to save time. When the drawing, stretching, and twisting of the thread are thus accomplished, the mule disengages itself from the parts of the machine by which it has been driven, and then the attendant spinner returns the carriage to the rollers, again to perform its task. While returning to the roller, the thread which has been spun is wound or built on the spindle in a conical form, and is called a *cop*. The mule-jenny is a complex piece of mechanism, and requires to have all its parts very nicely fitted and adjusted.

The *Self-acting mule* contrived by Mr. Roberts, and improved by later inventors, is a beautiful example of automatic mechanism. The carriage of this mule, after having drawn out and stretched and twisted the thread, is returned again to the rollers by mechanical means without the guidance or intervention of any intelligent agent, the only attendance required being that of children to join such threads as may have been accidentally broken in the stretching. This self-acting mule is even more complex in its arrangements than the original machine, and hence great doubts were entertained as to its successful working; but it has triumphed over all difficulties. Its advantages as regards economy, and rendering the manufacturer independent of a class of workmen who frequently proved refractory, are so great, as to have led to a general adoption of the machine.



[Carriage of Self-acting Spinning Mule.]

If the yarn spun with the mule-jenny be intended for use as weft in the factory where it is produced, the cops are at once applied to the shuttle; but when intended for warp, and generally when exported, the yarn is reeled into hanks each 840 yards in length, for performing which operation a *Self-acting reel* has been contrived. This process is attended by young women. The diameter of the reel is 4½ feet; when it has performed 80 revolutions, a *lay* is formed measuring 120 yards, and seven of these lays make up a hank. Each hank is separately tied round with a thread, and weighed to ascertain its fineness; the different sizes are then put by themselves, and separately packed in paper bundles of either five or ten pounds weight.

Fine yarns are usually singed, in order to remove their loose downy fibres and to give them smoothness. This is accomplished by subjecting the thread to the action of a series of coal-gas flames, through or over which it is several times passed with a degree of quickness sufficient to prevent burning.

Cotton *thread*, for sewing, is made by laying together two or more yarns of equal quality, and twisting them; for which purpose distinct machinery is employed. Previous to the doubling and twisting, the yarn is passed through a trough, containing a thin solution of starch; the twist is given in an opposite direction to that applied by the spinning machine, causing the thread to resemble in this respect organzine silk.

Scarcely any operation in a cotton mill, we thus see, is carried forward without the intervention of a machine, by which the work is done with greater precision, and also with greater celerity, and consequently greater economy. The packing of the hanks of yarn into bundles is the work of a *bundle press*, by means of which the hanks are pressed into a small compass, the power of the machine enabling females to exert sufficient strength for the purpose. Even here, however, steam power is sometimes employed.

The degree in which the inventions that have here been noticed have reduced the expenses attending this branch of manufacture is great almost beyond belief. One pound of the yarn known as No. 100 was, in the year 1786, worth 38*s.*; in 1791, it was 29*s.* 9*d.*; in 1795, 19*s.*; in 1799, 10*s.* 9*d.*; in 1807, 6*s.* 9*d*; in 1832, 2*s.* 11*d.*; and in recent years it has been still lower. The average waste in spinning cotton is considered to be about 1½ oz. per pound; it is very much higher in fine yarns than in coarse, and this is one reason for the increased price of the former. Mr. Ainsworth, an eminent Lancashire manufacturer, has recently pointed out the ratio which raw material bears to labour, in four varieties of textile manufacture, thus:—

				For finished Goods.
1 lb. wool for flannel costs	1*s.* 6*d.*	+ 1*s.* 7*d.*	for wages	= 3*s.* 1*d.*
1 lb. wool, for coarse cloth costs	1*s.* 2*d.*	+ 4*s.* 0*d.*	„	= 5*s.* 2*d.*
1 lb. flax for shirting costs	0*s.* 10*d.*	+ 1*s.* 6*d.*	„	= 2*s.* 4*d.*
1 lb. cotton for sheeting costs	0*s.* 6*d.*	+ 0*s.* 6*d.*	„	= 1*s.* 0*d.*

The mechanical inventions relating to the various processes of cotton manufacture, patented or otherwise, are, as has been already implied, numerous almost beyond belief. The records of the Patent Office, now placed in such admirable order under the superintendence of Mr. Bennett Woodcroft, show this conclusively. It is not possible to give the number of patents with accuracy, because some of them relate to wool and flax as well as to cotton; but it is pretty evident that the last-named fibre occupies the prominent place. Down to the close of the year 1858 there had, since the commencement of the patent system, been 256 patents granted relating more or less to the cleaning, spinning, separating, scutching, and batting of fibrous materials; 82 containing provisions relating to the carding, combing, drawing, doubling, and roving of the materials thus prepared; and the enormous number of 1376 touching in a greater or less degree the processes and apparatus for spinning, twisting, and thread-making. It must not, as just stated, be understood that all these related to cottons; nor that there were 2457 separate patents relating to textile materials, seeing that some of the patents comprise within themselves the characteristics of all three lists, or of two out of the three; but it is quite certain that the patents relating strictly to the cotton manufacture are many hundreds in number. All these are irrespective of weaving processes, which have been made the subjects of a distinct series of patents.

As the weaving of cotton does not differ much in principle from that of linen, woollen, and silk, it will suffice to describe them all in one article. [WEAVING.] The statistics connected with the manufactured products of cotton-mills will come most suitably into the subjoined article [COTTON TRADE AND CONSUMPTION], as will likewise a brief notice of the cotton manufacture in foreign countries.

It would not be right to close this article without a few lines descriptive of those important establishments, the cotton-mills of the north—those extraordinary centres of industry, which have stamped a character on the counties containing them. It is computed that, in 1859, if we draw a circle of thirty miles radius around Manchester, that circle will be found to contain more inhabitants than a circle of similar size having London in its centre. Liverpool, the great port for landing raw cotton and for shipping manufactured cotton goods, is just within the circle: Manchester, the cotton metropolis, is by the terms of the argument in the centre of the circle; while other parts of the area include the great towns of Preston, Chorley, Blackburn, Accrington, Clitheroe, Burnley, Haslingden, Bacup, Rawtenstall, Bolton, Bury, Middleton, Oldham, Ashton, Staleybridge, Dukinfield, Hyde, Glossop, Mottram, Stockport, &c.—all of which contain immense establishments for spinning, weaving, bleaching, or printing cotton; and there are so many similar establishments occupying the valleys and roads between those towns, that the whole area may be regarded as one large workshop. The same may be said, in a smaller degree, of the district around Glasgow. Some of the mills spin cotton only, some weave it only, while some spin and weave. Some kinds of cotton goods are more largely made than others in particular towns; fine muslins in one, shirting calicoes in another, fustians in a third, and so on. Most of the spinning and weaving mills are buildings of vast size, speckled over with windows on every side. Some of them have six or seven hundred windows each, which give light to seven or eight stories or ranges of rooms. In those of improved construction, there is apparatus for lifting the workpeople, or some of them, from story to story, thereby lessening the fatigue and the consumption of time involved in ascending staircases. As one part of the perfect system which has gradually become organised in this trade, it is customary to haul up the bales of cotton to the highest story of the building, and then gradually lower the material from story to story until it leaves the bottom range in a finished state; thus the opening, the mixing, the scutching, the carding, the drawing, the roving, and the spinning, follow in their proper order, in rooms occupying different heights in the range of building. If it be a weaving as well as a spinning mill, the weaving machines or power-looms, sometimes fifteen or eighteen hundred in number, are usually placed in a lower and separate building, called the weaving-shed. Nothing is more admirable in the whole arrangement than the manner in which the moving power is conveyed from story to story, from room to room, by means of highly-wrought shafting and wheel-work. The steam-engine may be outside one end of the building, and yet its working efficacy may be felt at the other end, perhaps two or three hundred feet distant. If the mill be in a country district, with a hill close at hand, the architect often plans that the chimney-shaft shall be built on the top of the hill, with a flue leading to it under-ground from the furnaces; this is equivalent to a great increase in the height of the chimney, and in the strength of the draught which passes through the furnace. In the days of Arkwright and the elder Strutt, the mill builders looked out anxiously for a valley, where a stream might afford moving power for a water-wheel; but in the present days of steam-power, the cotton-spinner reckons little on the proximity of a river. In those days, canals were the great channels of communication, along which raw cotton was carried to the mill and manufactured cotton goods conveyed away from it; the transit is now effected almost entirely by railway. There are nearly four hundred miles of railway in Lancashire alone, mostly maintained by the cotton trade; besides those belonging to the cotton districts in the neighbouring counties. These four hundred miles have certainly not cost less than twenty millions sterling; which may, in a certain sense, be regarded as one portion of the fixed capital expended in our gigantic cotton manufacture.

The workers in cotton mills, with the arrangements for their protection, will be noticed in a later article. [FACTORIES.] Some of the numerous processes to which cotton goods are subjected have been described in earlier portions of this work. [BANDANA; BLEACHING; CALENDERING; CALICO PRINTING]; and another class of operations will be found noticed under DYEING.

COTTON TRADE AND CONSUMPTION. Having, in COTTON CULTIVATION AND SUPPLY, passed under review the chief circumstances connected with the growth of this important fibre, and its shipment to the busy marts of industry; and in the article COTTON MANUFACTURE, having described the principal processes whereby the fibre is spun for the use of the weaver—we shall be prepared, under the present heading, to trace the wonderful course of trade in the manufactured commodities.

And first, in relation to our own country, concerning which the available sources of information are abundant and trustworthy.

The unprecedentedly rapid increase in the consumption of cotton in Great Britain, soon after the year 1786, resulted almost entirely from the inventions of Arkwright, Hargreaves, and Crompton, followed, at later dates, by those of Cartwright, Ratcliffe, and Roberts, already adverted to. Had it not been for these inventions, British artisans could not have competed successfully with the spinners and weavers of India. The Hindoos possess so much skill in this kind of work, and are content with so low a rate of wages, that their muslins and calicoes would have continued to beat those of England out of the market, had not the latter been aided by machinery. Even when this difficulty was overcome, the peculiar monopoly of the East India Company retarded the opening of a market for British manufactures. It was not until the present century had considerably advanced that British cotton goods found their way to India in any notable quantity. Another circumstance deserving remark is, that the English weavers were slow in arriving at an equality with the Hindoos in the durability and general excellence of the product; it was the cheapness of price, rather than the improvement of quality, which brought about the revolution in the trade.

It will be convenient and instructive to trace the advance of this remarkable department of British commercial industry in successive epochs.

Before 1800. The statistics of the trade during the last century are not much to be relied upon; many of them were mere estimates rather than authenticated returns. So far as they go, however, they may briefly be mentioned. In the year 1700 there were about 1,000,000 lbs. of cotton used in Great Britain, requiring the services of 25,000 persons to work it up—clearly indicating, by the large ratio of labour to material, a period of hand-spinning and hand-weaving. In 1720, the consumption was 2,200,000 lbs.; and in 1764, about 3,900,000. In 1775, before Arkwright's patent became established, the consumption was 4,800,000, which doubled by the year 1781. With 1786 began the new order of things. In the next following year the consumption was 23,000,000 lbs.; to work up which there were 143 cotton factories, 550 mule-jennies, 50,000 mule-spindles, 20,070 hand-jennies, 1,600,000 jenny-spindles, and 60,000 operatives. In 1790, the consumption was nearly 31,000,000 lbs.; and in 1800 upwards of 51,000,000 lbs. Before the year 1775, only low numbers, or coarse yarn, could be spun, and in a quantity insufficient for the wants of the weavers; but the great inventions of Arkwright, Hargreaves, and Crompton enabled the spinners to overtake the weavers—until Cartwright invented power-loom weaving, when the balance turned the other way. About the year 1790 the British manufacturers began to look out for an increased supply of foreign cotton; they felt that they could work up the raw material more rapidly than it was at that time obtainable. The East Indies effected a little, but only a little, towards augmenting the supply. The United States made an energetic response to the appeal. Eli Whitney's newly invented cotton-gin enabled the planters to clean their cotton for the market with a rapidity greatly exceeding that of the previous process; and thus, with an increased demand and an increased power of supply, the United States cotton trade spread in the way already indicated. During the last ten years of the century, the price of United States cotton varied from about 1*s.* 3*d.* to 1*s.* 6*d.* per lb. on an average of all the qualities.

1801 *to* 1810. The present century opened with every indication of a rapid extension of the cotton manufacture of Great Britain; and the result fully corresponded with the symptoms. The consumption was 54,000,000 lbs. in 1801, and 58,000,000 in 1806; a small portion was re-exported to other countries, in addition to the above, so that the total import was somewhat larger. The price of cotton gradually lowered; but the British manufacture had not yet extended to the degree which would leave any considerable surplus for exportation; nearly all the woven cotton goods were used at home.

1811 *to* 1820. The consumption rose from 90,000,000 lbs. to 150,000,000 lbs. per annum, during this period, after making allowance for a small re-export of raw cotton. Already had United States cotton attained such an ascendancy in the market, that towards the close of this decennial period, it constituted 53 per cent. of all the cotton used in Great Britain—the remainder being 31 per cent. from Brazil, 10 per cent. from the East Indies, and 6 per cent. from the West Indies. British manufacturers had by this time discovered the valuable fact, that, if the East India Company would afford trading facilities, India was quite willing to take in large quantities the produce of our looms. About 800,000 yards of British cotton goods were sent to India in 1814; in 1818 the quantity was 1,600,000 yards; and in 1820 no less than 9,000,000 yards. Altogether, it is supposed that, in 1820, our manufacturers found foreign purchasers for 248,000,000 yards of cotton piece-goods, and 23,000,000 lbs. of cotton-yarn, sold to be worked up in countries where they could weave more cheaply than spin.

1821 *to* 1830. There are conflicting accounts of the quantity of cotton used in Great Britain during these ten years. One authority sets down the quantity imported in 1821 at 157,000,000 lbs., and in 1830 at no less than 264,000,000 lbs.; in each year all except 5,000,000 or 6,000,000 lbs. were worked up in our own mills and workshops. Another authority gives higher figures. One cause of this discrepancy is, that many computers give their statistical entries in *bales*, and then guess at the probable number of pounds in an average bale of the period in question. The prices of cotton at Liverpool, during this decade, varied from 7*d.* to 12*d.* for average United States growths, 8*d.* to 15*d.* for Brazilian, and 5*d.* to 8*d.* for East Indian. It has been computed that in 1830 there were 223,000,000 lbs. of yarn and twist made in Great Britain, 64,000,000 lbs. of this quantity exported, and 412,000,000 yards of cotton piece goods exported—the value of these exports being about 19,000,000*l.*

1831 *to* 1840. We now arrive at a decennial period during which the workers in our cotton mills had become so numerous as to enlist the sympathies of the nation, in so far as regarded the unprotected or ill-protected women and children comprised among the number. What was the nature of the legislative interference, will be noticed under FACTORIES; a few particulars concerning actual numbers will suffice in the present case. The quantity of cotton imported increased with gigantic strides; it was 364,000,000 lbs. in 1835, and 592,000,000 lbs. in 1840. A steady increase took place at the same time in the quantity re-exported for manufacture in foreign countries; but this portion continued to bear a very small ratio to the whole weight. By the year 1840 the United States had acquired a greater ascendancy than at any former period in the supply of cotton to Great Britain; not only had their quota increased, but the increase had been more rapid than that in other countries. Of all the cotton purchased by Great Britain in that year, no less than 76 per cent. was from the United States—the other ratios being, 14 per cent. from the East Indies, 6 per cent. from Brazil, 2¼ per cent. from Egypt, and 1¾ per cent. from the West Indies and miscellaneous countries. There had been an advance of ratio in quantities in East Indian and Egyptian, and a decline in Brazilian and West Indian. Prices, which in 1835, averaged 10½*d.* for United States cotton, 14¼*d.* for Brazilian, and 7¼*d.* for East Indian, fell in 1840 to 6*d.*, 9¼*d.*, and 4¾*d.*, respectively. This was a highly flourishing state of things for the manufacturers; they obtained cotton cheaply and abundantly; they had the command of the best machinery, and an ample supply of labour; and a long continuance of peace maintained a wide field of foreign trade open to them. It was estimated that 281,000,000 lbs. of cotton yarn and twist were spun in Great Britain in 1835, and 407,000,000 in 1840; of these large quantities, 83,000,000 and 118,000,000 lbs. respectively, were exported. The exports also included 558,000,000 yards of cotton piece goods in 1835, and 791,000,000 in 1840. Piece goods and yarn together, the values were supposed to be 22,000,000*l.* in 1835, and 25,000,000*l.* in 1840—though some computers have made these figures much higher. As to the amount of fixed capital invested, Mr. M'Culloch, Mr. Baines, and Mr. Kennedy, all endeavoured to make separate estimates about the year 1835; they proceeded on different bases, and their results were not in harmony; nevertheless, they did not depart very far from a medium estimate of 34,000,000*l.* Mr. Woodbury, an American authority, in comparing the cotton manufacturing operations of different countries for the year 1833, put down Great Britain at 9,500,000 spindles, and 1,500,000 persons directly or indirectly supported by the cotton manufacture. The last-named kind of estimate is one that must always be received with caution; for unless we know the limits which a computor assumes, we can never be sure of the meaning of his results. For instance, there are first the actual workers in the spinning and weaving mills; then there are the hand-loom weavers *out* of the mills; next come the bleachers, dressers, dyers, printers, and calenderers, who finish the woven goods for the market; another group comprises those who manufacture cotton into hosiery, lace, bobbin net, and various other articles; to these must (or may) be added the artisans employed in making the spinning and weaving machines and implements; and lastly, there are the wives and children or other dependents (themselves not engaged in earning money) of men employed in the above-named trades. Computers not only differ in the number of the groups which they include, but they do not always render it clear how far their estimates extend. In the instance of Mr. Woodbury, it is evident that he must have given a very wide extension to the meaning of the terms "supported by the cotton manufacture." The actual workers in cotton factories, in 1835, amounted to 220,134; and the number of power-looms in the mills was 109,626. The *obtainable* power of those looms, if all fully employed throughout the year upon a somewhat heavy class of goods, was estimated at 700,000,000 yards woven in a year; although the real produce was of course much below this. The number of hand-looms at that time could only be guessed at; it was roughly estimated from 200,000 to 250,000. It affords a curious illustration of the vastness of the manufacture, that the cotton weavers in that year used 650,000 bushels of flour, for the mere purpose of dressing the warp-threads before weaving. The factories were ascertained to be 1304 in number—that is, the spinning and weaving mills, in which the 220,134 operatives were engaged; the total number supported by the manufacture, in the wide acceptation above adverted to, was set down at 1,400,000, being less than Mr. Woodbury's estimate made two years before. The commissioners appointed to inquire into the circumstances connected with the employment of women and children in factories (preparatory to legislation on that subject), made a valuable analysis of the mode in which labour was distributed in the mills; from which the following table was prepared, showing the number employed and the wages earned in each department:—

	Number of hands.	Net Monthly earnings.
		£
Cleaning and spreading	**4,998**	**8,622**
Carding	**40,484**	**75,276**
Mule-spinning	**65,216**	**139,661**
Throstle-spinning	**7,709**	**11,616**
Reeling	**14,638**	**22,817**
Weaving	**75,055**	**168,664**
Roller-covering	**725**	**1,765**
Engineers, &c.	**3,975**	**15,987**

The aggregate does not exactly correspond with the 220,134 for the year 1835; but the periods were perhaps not quite identical. Of the total number, 60,393 were men, 65,774 women, and the rest children. The average wages paid at that time to children and young persons, was from 2*s.* 9*d.* per week for boys nine years of age, to 8*s.* 2*d.* for young persons of eighteen; adult wages varied greatly, according to the degree of skill required in the several processes. The cotton yarns woven at that period varied in price between the wide limits of 1*s.* per lb. (for No. 12 water-twist) to 27*s.* per lb. (for No. 250 mule-twist).

1841 *to* 1850. The arrival of this period was marked by a notable manifestation of the influence possessed by the cotton manufacturers and merchants of England. The 'cotton interest' or 'Manchester interest" was now so great, that statesmen began to bend to it in a manner never before exhibited. The immense shipping arrangements at Liverpool, connected with the importation of cotton; the vast monetary dealings between the Liverpool merchants and the Manchester manufacturers; the expenditure of capital in beginning to cover Lancashire with a network of railways, mostly for the accommodation of this particular trade; the mills, the machines, the work-people, employed in the trade—all had now advanced to such a degree of importance, as to render it impossible for statesmen to ignore the fact that a new power had arisen in the north, which must influence the legislation of the country. It was this power, more than any other which can be named, that brought about the systematic change of the import duties on foreign commodities, and especially on corn. The importation of cotton in 1845 was about 1,850,000 bales: equivalent, with the average weight of bales at that time, to about 722,000,000 of pounds; of which 43,000,000 were re-exported. Owing partly to a lessening of supply, and partly to the re-action after a period of excitement, the import of cotton in 1850 exhibited a falling off; it amounted to 1,750,000 bales, or 664,000,000 of pounds, of which 102,000,000 were re-exported. In reference to the total quantity of yarn and twist manufactured, the portion of this quantity which was exported to foreign countries, the length of woven piece goods exported, and the value of both kinds of exports, the two years in question exhibited the following figures:—

	Yarn and Twist manufactured.	Yarn and Twist exported.	Piece Goods exported.	Value of exports.
	lbs.	lbs.	Yards.	
1845	495,000,000	131,000,000	1,092,000,000	£26,000,000
1850	529,000,000	124,000,000	1,358,000,000	28,000,000

The price of cotton fell in 1845 to a level never before known, and this was one cause of the large importation in that year. Average United States cotton was at 4½*d.* per lb., Brazilian at 6½*d.*, and East Indian at 3*d.* This was a year for large profits among the Lancashire manufacturers; they had an abundance of cotton at a low price, and sent out their manufactured goods to all accessible quarters. The intense desire to gain admission to additional foreign markets, for the sale of English manufactured cottons, was one reason for the vigorous agitation which led soon afterwards to the revision of Customs' duties; on the ground that if foreign countries were permitted to send their raw produce nearly or quite duty free to England, they might the more readily admit English manufactured goods on fair and moderate terms into their own ports. By the year 1850, the price of cotton had risen considerably; the three kinds above named exhibiting averages of 7½*d.*, 8*d.*, and 5*d.*, respectively. Concerning the operatives by whom the cotton was worked up, there was an estimate in 1846 that the cotton mills of the United Kingdom employed 316,327 persons; of whom 134,091 were males, and 182,236 females. A more detailed estimate, applicable to the year 1850, gave the following figures: cotton mills, 1932; moving-power therein, 83,000 horse-power; spindles, 21,000,000; power-looms, 247,000; children employed in cotton-mills, 14,993; young persons and adults, 315,931; total mill-hands, 330,924; of whom 189,423 were females.

1851 *to* 1859.—We now come to those recent years in the history of the British cotton manufacture which have been marked by great agitation and uneasiness; owing mainly to the extraordinary way in which England is dependent on the United States for a supply of cotton, and to the alarming degree in which any diminution in this supply augments the price of the raw material. It has just been shown that, in the year 1850, the quantity of raw cotton imported was about 664,000,000 lbs. Without touching upon the intermediate years, we will at once proceed to the three most recent years concerning which returns are yet obtainable—1856, 1857, and 1858:—

	1856.	1857.	1858.
	cwts.	cwts.	cwts.
From United States	6,964,643	5,846,054	7,439,623
" Brazil	194,197	267,061	196,321
" Egypt	307,134	219,038	341,360
" East Indies	1,611,577	2,235,162	1,185,023
" Other countries	63,571	87,318	102,961
	9,141,122	8,654,633	9,265,288

Here we see that the Board of Trade returns introduce an additional complexity; we have not only to deal with *bales* and *pounds* of cotton, but in this instance with *hundredweights.* Without calculating the probable number of bales, it will suffice to convert these quantities into pounds, and then we find them to amount in round numbers to the following astounding totals: 1023,000,000 lbs. in 1856; 970,000,000 lbs. in 1857; 1034,000,000 lbs. in 1858. The relative falling off in East India cotton in 1858 may doubtless be attributed to the disturbance of industry and commerce occasioned by the mutiny. A portion of raw cotton, as we have before seen, is sold again by English dealers to foreign countries, chiefly in the north of Europe; this portion amounted, in the three years above-named, to about one-seventh of the total quantity imported. The ratios from different countries, in the first of these three years, were as follow: 71 per cent. of United States cotton, 19 per cent. of East Indian, 5 per cent. of Brazilian, 4½ per cent. of Egyptian, and ½ per cent. from miscellaneous sources. The next table relates to the exports of manufactured cottons, in 1858, in which it will be desirable to distinguish the chief countries to which the goods were sent:—

CALICOES, CAMBRICS, MUSLINS, FUSTIANS, AND MIXED STUFFS.

Countries.	1858.
	£
Hanse Towns	929,466
Holland	540,450
Portugal	718,662
Turkey	2,779,227
Syria	621,904
Egypt	770,078
United States	2,613,588
Foreign West Indies	816,456
Brazil	1,839,425
Buenos Ayres	440,417
Chili	414,156
Peru	491,207
China	1,821,570
Java	532,863
Gibraltar	416,466
British North America	450,780
British West Indies	562,428
East Indies	9,299,359
Australia	612,215
Other countries	5,335,998
	32,006,715
Cotton yarn	9,573,320
Cotton stockings, thread, lace net, and small wares	1,387,549
	42,967,584

In 1856, the total amount had been 38,232,741*l.*; in 1857, it was 39,073,420*l.*

It will be seen that, according to this remarkable table (excluding the entry "Other countries," which is made up of many small items), the largest customers for British cotton manufactured goods are the East Indies, the United States, Turkey, Brazil, and China; these take rather more than half of the whole quantity. Yarn, on the other hand, as the spun material for weaving, is exported most largely to those European countries in which weaving is carried on to a considerable extent; thus, the Hanse Towns and Holland alone purchased cotton yarn from England to the average annual value of about 4,000,000*l.* during the years 1856–7–8. It is necessary to remark, however, that the Hanse Towns (Hamburg, Lübeck, Bremen, &c.) are not in themselves cotton manufacturing towns to any great extent; they are simply the ports at which cotton is landed, for distribution in Prussia and North Germany.

This will be a convenient place in which to advert to a source of confusion likely to lead to error, in comparing English and American cotton statistics. In England the commercial year ends on December 31; but in the United States the date August 31 is adopted—being that on which the total amount of the summer's crop is ascertained. The total crop for the twelve months ending August 31, 1859, was the largest on record, being more than 3,700,000 bales; and England, it is known, took a larger quantity than in any former period of equal extent, being more than 2,000,000 bales; but we cannot compare these numbers strictly with English estimates for 1857 and 1858, for the reasons just stated; and also because it is not certain that the bales present the same average weights as before.

Concerning the mill-industry of recent years, we have two computations, one for 1851 and one for 1856. In 1851, the cotton-mills of the United Kingdom are said to have employed 470,317 persons; of whom 222,612 were males, and 247,705 females. In 1856, the following figures were exhibited: cotton-mills, 2210; moving power therein, 97,000 horse-power; spindles, 28,000,000; power looms, 299,000; children employed, 24,684; young persons and adults, 354,565; total mill-hands, 379,249, of whom 222,027 were females. It is supposed, although there are no means of accurately determining this point, that the total quantity of yarn spun in 1857 was about 740,000,000 lbs.; of which about 24 per cent. was exported in the state of yarn, and the remaining 76 yer cent. worked up in this country into woven and other goods.

There are features connected with these statistical returns, coupled with those of the preceding decennial period, which have excited anxious attention among the Lancashire manufacturers. From 1841 to 1848 there was, at the end of each year, an average stock of cotton on hand, at Liverpool (almost the only port of landing: Glasgow being the next in rank), equal to more than half a year's consumption for the whole of the United Kingdom; but from 1849 to 1857, the stock in hand barely reached eighteen weeks' consumption; and in 1856, it was as low as twelve weeks'. In 1845, which was a golden year for manufacturers, after paying 10,000,000*l.* for raw cotton, they received 45,000,000*l.* for yarn and manufactured cotton goods; leaving 35,000,000*l.* for machinery, fuel, dyeing, bleaching, printing, wages, interest of capital, and profit. Twelve years afterwards a contrast was exhibited, very unsatisfactory to the manufacturers. In 1857, they paid the enormous sum of 26,000,000*l.* for raw cotton, not so much on account of the increase of quantity as the increase of price; the money obtained for the yarn and manufactured goods was 56,000,000*l*., leaving 30,000,000*l*. for machinery, fuel, dyeing, bleaching, printing, wages, interest, and profit. They had done much more business than in 1845, but under much less favourable circumstances; in 1845, the raw cotton had cost less than a quarter of the money for which the manufactured produce was sold; whereas, in 1857, the ratio amounted to nearly one-half. The gradual diminution of the stock on hand at Liverpool, and the immediate rise of prices in certain years, led to that movement at Manchester which was briefly adverted to in the first of these three articles. When Sir James Weir Hogg, on the part of the East India Company, offered facilities for the researches of any accredited person, who might go out to India to inquire into all the circumstances of cotton culture in that region, the Manchester manufacturers took the matter up, and deputed Mr. Mackay as their commissioner or agent. This gentleman went out in 1852, with an intention of examining the Bombay and Madras presidencies; but his health broke down when his work was only half completed. He died in India; and so much of his report as had been finished was published under the editorship of Mr. Robertson in 1853. The volume contains a large amount of valuable information; and it was fully expected that the Manchester manufacturers would apply it to some useful purpose. But here again was presented an example of narrowed attention to individual interests, and a neglect of the broader interests of the trade, —and it may be added, of the nation in general. There happened to be two years of good supply and moderate prices of cotton and high profits on manufactured goods; and while this state of things lasted, Mr. Mackay's report was forgotten. When, however, the year 1856 exhibited a rise in the prices of United States cotton, and 1857 a still greater rise, manufacturers again took the alarm; again felt it a duty to inquire whether an increased supply of cotton can be obtained from other countries, so as to lessen the dependence of Great Britain on the United States.

It was under these circumstances that the Cotton Supply Association was established in 1857. Many active Lancashire men sought to interest the trade generally in the importance, and even necessity, of fostering the cultivation of cotton in countries where it had hitherto been too much neglected, especially the East Indies. The Association held its first anniversary meeting in April, 1858. During the preceding twelve months, many meetings had been held in the large towns of the north, to elicit opinions by discussion and comparison of data. A general opinion prevailed that India was the chief source to look to. A project was drawn up, to propose to the government an expenditure of 20,000,000*l*. in that country during five years, in the construction of roads, bridges, railways, tramways, piers, landing slips, irrigation canals, and navigation facilities; the interest of the money, and possibly a redemption fund, to be provided for by tolls. Whether such a large demand would have been acceded to under any circumstances, is doubtful; but the whole movement was speedily checked by the formidable mutiny. Even a limited application of 300,000*l*. for some of these purposes could not be obtained. The enormous outlay consequent on the suppression of the mutiny placed the Indian exchequer in a position ill-fitted for the direct undertaking of expensive public works; and the new council for India, after the transfer of the company's powers to the crown, was obliged to direct its energies to the defraying of costs already incurred. The Cotton Supply Association, in the course of its labours, sent circulars to the British consuls in all the cotton-growing countries, inviting information concerning the possibilities of an increase of supply. The replies given comprised many valuable statements. The ruling authorities in nearly all those countries expressed great eagerness to aid the object in view; making applications for good seed and efficient working machinery. The association purchased a hundred tons of the best American cotton seed, and sent it in small quantities to the several countries. Nevertheless, the ruling men in the association, in this their first report, complained in strong terms of the want of sufficient support among the Lancashire capitalists. The cotton dealers of Liverpool and the cotton spinners of Manchester entered with no largeness of feeling into the scheme; they subscribed so slenderly, that the association had not funds for carrying out the intended plans. At the next annual meeting, however, held in May, 1859, the report showed that the second year's operations of the association had been marked by that energy which Lancashire men can (if they will) bring to bear on their proceedings. There was, it is true, a complaint that Liverpool and Glasgow were still listless; but Manchester was on the alert, and so were most of the spinning towns. During the second year the association received two thousand communications from the government departments, the new Indian council, the British consuls abroad, and societies and individuals in various parts of the world, relating to the encouragement of cotton-growing in places suitable for it. Grants of cotton-seed, varying from one bag to two hundred each, had been made and forwarded to Bombay, Madras, Calcutta, Ahmedabad, Hyderabad, Malabar, Ceylon, Singapore, Sydney, Savanilla and Baranguilla in South America, Honduras, Guatemala, Cuba, Jamaica, Hayti, Tunis, Lagos, Fernando Po, Sierra Leone, Cape Coast Castle, Natal, Monrovia, Macedonia, Aleppo, Jaffa, Sidon, Kaiffa, Broussa, Salonica, Constantinople, Messina, Attica, Argolis, Laconia, Arcadia, Achaia, Eubœa, and many other places. Cotton-gins were forwarded to several of the above-named towns and countries; and cotton-presses were sent to Cape Coast Castle. Medals and prizes were offered for the best samples of cotton grown in Liberia. A periodical called the 'Cotton Supply Reporter' was established, containing useful communications obtained from all parts of the world relating to the growth of cotton; it was regularly forwarded to all associations and individuals likely to be able to aid in the general object. Public trials of cotton-gins were held, with the view of concentrating the attention of machinists and inventors, in the hope of ultimately obtaining machines of a more efficient character than those at present in use. Acting on suggestions received from India, the association began experiments and invited assistance on the improvement of the simple Indian *churka*, or roller-gin,—appreciating the importance of having some easily managed contrivance which the Hindoos could use in their own cottages. If this were done, the Hindoos might be able to convey to the trading stations clean cotton instead of cotton in the seed, thereby reducing to one-third or one-fourth the weight to be carried. It was expected that the autumn of 1859 would witness the arrival at Liverpool of a large quantity of excellent cotton from places in which the cultivation had been mainly due to the exertions of the association.

We may now give a few figures concerning duty, prices, and capital, in relation to the British cotton manufacture.

The highest duty ever charged by the Customs' department on the raw material imported was between the years 1805 and 1809, when it amounted to 25*s*. 3¾*d*. per cwt. (about 3*d*. per lb.) for the produce of "non-favoured" countries. The lowest duty prevailed between 1833 and 1845, when it amounted to 4*d*. per cwt. on cotton from British provinces, and 2*s*. 11*d*. per cwt. on cotton from all other countries. The duty was altogether removed in the last-named year. The prices of the manufactured goods are subject to two remarkable disturbances: one due to the cheapening effects of improved machinery and processes; and the other due to the difference in the amount of labour on fabrics similar in weight, but not in fineness. It is a recorded fact that sixty years ago as much as 6*s*. per yard was paid for a calico wedding dress, which would now be manufactured at about 3*d*. The same kind of yarn which sold for 38*s*. per lb. in 1786 can now be sold with a profit at 2*s*. 6*d*. At the present time a pound of cotton-yarn is in some cases worth only 11*d*.; in others, 21*s*. 6*d*.; depending for the contrast almost wholly on the difference in the amount of labour bestowed: in the last-named case the cotton costs 3*s*. 6*d*.; the labour, 18*s*. Concerning the amount of capital now invested in this colossal manufacture, the materials for computation are doubtful. Mr. Ellison, in 1858, estimated that there were 2210 cotton-mills in the United Kingdom; that they contained 28,000,000 spindles; that if all the buildings and all the spinning materials were estimated in cost at so much per spindle, they might be taken at about 24*s*. per spindle; that wear and tear had probably brought down this value to 18*s*.; that there were 299,000 power-looms, which, having cost 24*l*. each, might be set down at 20*l*. He thence derived the following figures:—

	£
Present value of mills and spinning machinery . .	25,000,000
Present value of power looms	6,000,000
Floating capital, stock in hand, wages advanced, &c. .	14,500,000
Cash at bankers	10,000,000
	55,500,000

In most of the foregoing details Ireland has been included with Great Britain. It has never occupied a distinguished rank in this department of industry. The manufacture was first introduced into Ireland in 1770, and it gradually extended; but the high price of fuel has always been a serious drawback. Many Glasgow firms send out spun yarn to Ireland to be woven into muslins and other cotton goods by hand-loom. It was supposed in 1855 that about 5000 persons were employed in the cotton manufacture in Ireland, chiefly in the province of Ulster.

Having thus traced the operations in the United Kingdom, we shall next take a rapid glance at the rise and present state of the cotton manufacture and the consumption of raw material in the chief foreign countries.

France.—The first import of cotton into France is said to have been in the year 1770. The first authentic record of quantities was in 1787, when the import amounted to about 10,000,000 lbs. From that time, during the long and dreadful war, little progress was made. In 1815 the quantity rose to 36,000,000 lbs.; in 1820, 45,000,000; in 1825, 55,000,000; in 1836, 57,000,000; and in 1846, 97,000,000: in 1850 it reached 375,000 bales; in 1856, 506,000 bales; and in 1857, 484,000. There is here the same complexity between *pounds* and *bales* as we have had occasion to notice in reference to Great Britain; and there is a further source of confusion in the adoption of the weight *kilogramme* in the French commercial tables. If, however, we assume the bale to be 400 lbs., the busiest year in the above list (1856) exhibits an import of about 200,000,000 lbs.—by far the largest ever known on the continent of Europe. The exports of French cotton goods, after the conclusion of the great war, rose in the following way: 29,000,000 francs in 1820, 43,000,000 in 1825, 55,000,000 in 1830, 57,000,000 in 1833. In 1850, the money paid for raw cotton was estimated (in English currency) at 10,000,000*l*., and the value of the manufactures produced at 16,000,000*l*.—indicating, if the entry be correct, either a very coarse quality of goods, or a very low rate of wages and profits. In the same year the French government tables gave the following figures: Cotton factories, 694; mule spinning-machines, 115,157; other spinning-machines, 15,362; spindles, 3,442,550; male adult operatives, 108,663, with average wages of 1*s.* 8*d.* per day; female adult operatives, 89,492, wages 10*d.*; children, 44,278, wages 5*d.*

Switzerland.—The Swiss do not wear many cotton garments; but they manufacture cotton for export to neighbouring countries. The first spinning machine was established at St. Gall in 1800. A considerable part of the Swiss manufacture consists in weaving by hand-looms the yarn which is imported ready spun from other countries; and in dyeing and printing piece-goods which have been woven abroad; in the latter department of the trade they have acquired a high reputation. A portion of the raw cotton imported by France is sold again to Switzerland. The republic worked up 22,000,000 lbs. of cotton in 1843, and 27,000,000 lbs. in 1851. The spinning capabilities have risen from 259,000 spindles in 1824, to about 1,350,000 spindles in 1858, in 270 factories.

Holland and Belgium.—These two countries are about on an equality in relation to the cotton manufacture. They produce fine, soft, and durable cotton goods. Much of their cotton is purchased from England. One of the curiosities of their trade is, that considerable quantities of yarn, when dyed red, are re-exported to England, for transmission to the East Indies; this seems to imply, that the quality of the dye is preferred to that of England. The cotton-trade of Holland is believed to be chiefly a transit one, the bales being sent onwards to the Rhenish districts. Taking the two countries together, Holland and Belgium imported 106,000 bales in 1850, and 170,000 bales in 1857. Belgium was supposed to have about 420,000 spindles in 1845, chiefly in the province of East Flanders.

Germany and the Baltic Ports.—Under the somewhat indefinite geographical designation, Germany, it is difficult to discover what is the amount of the cotton manufacture; for in some returns Prussia is included, but in others excluded; while the Baltic ports of landing might include many countries besides those belonging to the Germanic Confederation. It will probably include nearly the whole of the imports of northern and central Germany, Prussia, Russia, Sweden, and Denmark, if we combine the statistics of Germany and the Baltic Ports. In 1850 the importation amounted to 234,000 bales; in 1857 it had increased to 378,000 bales; and in 1856, it had reached 520,000 bales; the extraordinary activity being probably due to the renewed operations of peace after the Russian war of 1854–5. If the average of 400 lb. per bale may be taken (it was probably less than this), the imports of the year in question amounted to 200,000,000 lbs.

Although the imports of the respective German States cannot here be separated, the manufactures of several of them admit of being noticed. All the German States together were said to have 1,815,000 spindles in the year 1846, and 2,060,000 in 1857; but it is not clear whether Prussia was included in this group. Much of the cotton imported by Prussia in 1854–55 was merely in transit to Russia, whose ports were practically closed during the war. *Prussia* counted 5880 workers in cotton mills, and 172,000 spindles, in 1846; in 1858 there were supposed to be 425,000 spindles, in 26 cotton mills. *Saxony* is making a steady advance in the cotton manufacture, as shown by the following figures:—84 mills and 360,000 spindles in 1830; 116 mills and 475,000 spindles, in 1845; 134 mills and 605,000 spindles in 1858. The mills are mostly worked by water-power. The spindles vary from 120 to 21,000 in each factory, and mostly weave coarse yarns. In the year 1855 about 24,000,000 lbs. of cotton were worked up into 20,000,000 lbs. of yarn, worth 800,000*l.* The cotton was about in equal quantities from the United States and the East Indies. The fixed capital invested in the manufacture was estimated at the rate of about 30*s.* per spindle, and the working capital at 27*s.* There were 5979 men and boys employed, 5717 women and girls, or 11,696 altogether. The aggregate of wages paid was 136,000*l.*—about 11*l.* 11*s.* per head, or 4*s.* 5*d.* per week each operative on an average: a rate very much lower than that which prevails in England. It was computed that, of every 100*l.* received for the manufactured goods, 67*l.* went for raw cotton, 16*l.* 10*s.* for wages, and the remaining 16*l.* 10*s.* for working expenses, interest on capital, and profit; this affords another proof that both wages and profits must have been low. Of *Bavaria* we learn only a few facts; that in 1847 there were 11 mills, 56,000 spindles, and 1140 mill hands; and that by the year 1858 the mills had somewhat increased in number. The German States of *Hanover*, *Wurtemberg*, *Baden*, *Oldenburg*, and *Nassau*, were collectively entered in 1858 as possessing 32 cotton mills and 480,000 spindles.

Russia.—For the reasons already stated, the amount of import of cotton into Russia in recent years is uncertain; there are records, for instance, that 187,000 bales were landed at Baltic ports in 1857: but we do not know how many of these ports were Russian. Concerning the manufacture, there were 700,000 spindles in 1846. In 1853 the government returns told of 495 cotton mills, 2,000,000 spindles, 112,000 mill hands employed, and 41,000,000 lbs. of yarn produced. The import of raw cotton is steadily increasing, and that of English-spun yarn decreasing; showing that the Russians can now spin for themselves at a profit. There is good calico-printing conducted in the governments of Moscow and Vladimir.

Norway and Sweden.—The cotton trade and manufacture in these northern countries are small; but they are steadily increasing. It is computed that about 22,000,000 lbs. of cotton were imported in 1856, mostly at Gottenburg.

Austria and Italy.—It is not easy to separate the accounts of these two countries; for although most of the cotton landed at Trieste is forwarded north-eastward to Austria, Bohemia, &c., some of it is consigned to northern Italy. If we combine the imports at Trieste with those at all the Italian ports, we arrive at an average in eight years, 1850 to 1857, of about 160,000 bales; they exhibit a gradual diminution at Trieste, and a remarkable increase at the Italian ports—due, possibly, to a liberal policy on the part of the government of Piedmont. In Austria and Austrian Italy it is computed that, in 1846, there were 203 cotton mills, 1,270,000 spindles, and 28,000 mill hands: and that, in 1857, the mills had increased to 239, and the spindles to 1,740,000. The looms, in 1851, were 24,000 in number, mostly hand-looms. There is a probability that some of the cotton spun and woven in Bohemia and Moravia comes through France or Germany; and that thus the imports at Trieste are not a fair index to the totality of the Austrian manufacture.

Spain.—This fine but misgoverned country, in cotton manufactures as in most other things, is far behind the position which she ought to occupy. The spinning and weaving of cottons have slightly revived within the last few years; but they are far below the proper level for a country with fifteen millions of inhabitants. The cotton imported in 1857 was only 82,000 bales.

United States.—We now cross the Atlantic, and briefly trace a manufacture which is advancing with rapid strides. In the year 1789, the State of Massachusetts procured models of carding and spinning machines from England, and manufactured machinery to be put in operation by water-power; but the first cotton mill actually set to work in the United States was at Rhode Island in 1791. A second was built in 1792. Then a series of years occurred, during which the Americans made no advance whatever in the manufacture; the Southern States eagerly and successfully endeavoured to improve the culture and increase the sale of the raw material; but the Northern States took no steps to advance the spinning and weaving. It was not until the present century that anything noticeable was effected. In 1803 there were three cotton mills altogether, which were increased to four in 1804. In 1805 and the two following years there were ten mills built in Rhode Island and one in Connecticut. The war with England in 1812 induced the Americans to pay more attention to the home manufacture of cottons; and from that year this branch of industry has never flagged. The mills, which were only numerous enough to use up 1000 bales of cotton in 1805, and 10,000 bales in 1810, used 90,000 bales in 1815—employing (or perhaps supporting) in various ways 100,000 persons, and 40,000,000 dollars of capital. After this, power-loom factories were erected, and then the manufacture extended very rapidly. In 1830 the cotton worked up amounted to 127,000 bales; and in 1840 to 389,000; the value of the manufactured produce in these two years was about 4,700,000*l.* and 9,700,000*l.* respectively. America had too brisk a demand at home for these goods to induce her to export much; down to 1834 the export of cotton barely reached a value of half a million sterling annually. The cotton worked up in 1850 was about 640,000 bales; the mill hands were about 92,000; and the gross value of the manufactured produce 12,900,000*l.* In 1855 the cotton consumed was set down at 689,000 bales; and the value of the manufactured cotton goods at 14,800,000*l.* There can thus be no question that the cotton manufacture has spread widely and rapidly in the United States. Some English manufacturers fear that the Americans will by-and-bye spoil our market for spun and woven cotton goods in that country, and will even undersell us in other countries. They point to the fact that while our total exports of cotton were higher in 1857 than in 1856, and higher in 1858 than in 1857, that portion of the exports which went to the United States receded—being (in woven goods, excluding yarn, hosiery, and lace) 3,800,000*l.* in 1856, 3,100,000*l.* in 1857, and 2,600,000*l.* in 1858. On the other hand, as England is the great source for highly effective machinery; as coal and iron are abundant and cheap; and as wages are somewhat lower than in the United States,—it would appear that our country ought not to lose much in the race, in the long run.

A few words concerning the total consumption of cotton in *all* countries. In 1835, Mr. Woodbury, Secretary of the United States' Treasury, compiled, by order of the American Congress, and presented to the House of Representatives, a Collection of tables and notes on the cultivation, manufacture, and foreign trade of cotton. These were apparently prepared from all the authentic data at that time obtainable. Leaving out those Asiatic and African countries of whose industrial concerns we know so little, he estimated the consumption of cotton, in all the countries where commercial statistics are of any avail, at 490,000,000 lbs. in 1791; 630,000,000 lbs. in 1821; and 900,000,000 lbs. in 1834. Mr. Bazley, Chairman of the Manchester Chamber of Commerce, has made an estimate that in 1853 there were 1,500,000,000 lbs. worked up in Europe and America; of which, about one-half was wrought in England, and one-sixth in the United States. He further estimated, that if all this cotton were spun into the yarn known as No. 40, it would have required 47,000,000 spindles for this work. Another estimate, made in 1857, was to the effect that all the cotton worked up in Europe and America, excluding Asia and Africa, would in 1856 have amounted to 1,795,000,000 lbs. The probable *European* consumption for 1859 is about 1,300,000,000 lbs.

The most trustworthy authorities on the subject of this article are the same as those enumerated at the end of COTTON, CULTIVATION AND SUPPLY.

COUCH GRASS (*Triticum repens*) is a common and most troublesome weed which infests arable land, especially that which is of a light and mellow nature. It is perennial, and propagated both by seed and by extension of the root, which is long and jointed; each joint produces a fresh shoot, which, in a favourable situation, soon becomes a new parent plant, creeping along under the surface of the ground, and spreading over a whole field with great rapidity. It appears above ground like a blade of grass, or young wheat, which, in its tender state, is readily eaten by sheep. A seed stem afterwards shoots up, bearing a spike, composed of a middle rachis and alternate spikelets on each side. Each of these produces three or four seeds, protected by a long pointed chaff. Many of the seeds never come to perfection, owing to the increase of the roots; but in stiff ground and permanent pastures the roots are prevented from spreading, and then the seeds ripen. The principal propagation of the plant is by the root. The destruction and extirpation of couch grass is one of the first things which an experienced farmer sets himself to on taking occupation of land which has been neglected by the preceding tenant.

There is no law in this country which obliges a tenant to keep his lands free from weeds. There is something of the kind in Belgium, with respect to thistles and weeds which propagate by seed. An agricultural code is necessary to protect the landlord, and to prevent the woeful waste of labour produced by carelessness and bad management; and until such a code is established by the good sense and good feeling of neighbours, agriculture will never make rapid progress.

To extirpate couch grass a dry time must be chosen in summer; the land must be ploughed with a shallow furrow, to bring the roots to the surface; when the land is dry, it must be rolled to break the clods, and all the roots which lie near the surface must be gathered by the harrows or the couch rake. Sometimes the roots are matted into tufts, which can only be got up by means of a fork or prong. In this case no manual labour should be spared, especial care being taken not to break the roots, but to get them out whole, with all their offsets, if possible. After this, Finlayson's harrow may be used on light lands; or an instrument of a similar nature, called in Scotland a *grubber*, which will bring up all the roots that are within six or eight inches of the surface. When all the couch has been apparently eradicated, there will still remain a sufficient number of pieces and joints, broken off by the instruments and left in the ground, to produce a fresh crop of couch grass, especially if the land is frequently stirred, and showers intervene. Hence the vulgar notion that some lands breed couch, and that it is useless labour to be at much expense to eradicate it. In very heavy land, couch grass is easily kept down if an opportunity be taken to plough it to the surface in dry weather. The stiff clods in which the roots are entangled contract in drying, and in contracting destroy the texture of the root; when they crumble after a shower, the couch may be collected by hand, and burnt or carried away.

When a quantity of the roots of couch grass has been collected, they are usually burnt in heaps on the ground; the ashes serve to enrich the land in some degree. The curious in such matters do, however, assert that a much more profitable use may be made of them. When they are cleaned from the earth which adheres to them, they are found to be nutritious and farinaceous. Pigs eat them greedily; horses and cows will also eat them, especially when boiled or steamed; and weight for weight they contain not much less nutritious matter than potatoes. By maceration and washing, a good fecula is obtained, which, with hot water, forms a jelly-like arrow-root. The decoction of the root has been recommended as a cooling and demulcent beverage, and not without apparent reason; but if it be not thought worth while to wash and steam the couch for food, it is still more profitable to decompose it by means of lime than to burn it. For this purpose it should be gathered into a large heap and watered to induce fermentation. When it has heated, it should be turned over and mixed with quick lime in a considerable proportion; after two or three turnings with the spade, with an interval of a few weeks, it will be found converted into rich mould, which may then be spread over the land, either as a top-dressing for clover and artificial grasses, or ploughed in with the seed, where this method is practised.

To keep the land free from couch grass occasional summer tillage is necessary, which may be given when turnips are sown, or after an early crop, such as tares cut green, *Trefolium incarnatum*, or winter barley, without losing a crop. In a well-managed farm, couch grass should no more appear than docks or thistles. In Belgium a slovenly farmer is called a couch grass farmer.

Dogs eat the blade of couch grass from instinct to purge and vomit, and hence it has been named, in French, *chien-dent*, or *dog's tooth*; but the shape of the young shoots from the root may also probably have led to that name, for they have a great resemblance to a canine tooth.

It has been doubted whether, in some situations, couch grass might not be cultivated to advantage for its roots; no experiments, however, have been made in cultivating this prolific plant, as far as we know; but it is not unworthy the attention of those who take a pleasure in increasing the resources of agriculture. In years of great scarcity, the root of couch grass has been used in northern countries, mixed with flour, in making bread. It contains nothing unwholesome, and has a considerable resemblance in taste to the potato. The water in which the root of couch grass has been boiled may be used in the manufacture of bread; it would probably add considerably to the weight of the loaf when baked, but may perhaps communicate an unpleasant taste to it.

COUCHING. [CATARACT.]

COUGH, a violent expulsion of air from the lungs, attended, when the act of coughing recurs in rapid succession, that is, when there is a fit of coughing, with correspondingly rapid inspirations. Cough is a violent and sonorous expiration, during the effort of which a much greater quantity of air is expelled from the lungs than is returned by the corresponding act of inspiration.

The mouth, nose, fauces, pharynx, larynx, trachea, and bronchi, are lined by a highly irritable and exquisitely sensible membrane. That portion of this membrane which lines the air passages, properly so called, namely the larynx, trachea, and bronchi, possesses the properties of irritability and sensibility in so great a degree, that it cannot endure without the most violent excitement the slightest contact of a foreign body. It is necessary to the due performance of the function of the lung, one of the most important of the organic circle, that the tubes which lead to it should always be perfectly unobstructed; should invariably present to the air a free and uninterrupted passage. Among the expedients adopted to secure this purpose, one of the most important consists in the disposal and action of the membrane which lines the internal surface of the air-tubes. This membrane abounds with blood-vessels and nerves, by the action of which a large quantity of water is constantly separated from the blood, by which the tubes are kept in a state of perfect suppleness and moisture. A layer of the thick, tenacious, and viscid substance, called mucus, also separated from the blood by this membrane, is spread over its entire surface, by which it is defended from the irritating properties of the air, with which it must always be in contact. Moreover, the heat generated by the process of secretion warms the air in its passage to the lungs; and so great is the degree of heat communicated to the air during its progress, that before it reaches the lung it is brought to the same temperature as that of the blood. Accordingly when the lining membrane of the air passages is sound, when the temperature of the air ranges within a certain limit, and when the air is pure, holding in solution or suspension a foreign and noxious body, the external cold exciting air passes deep into the interior of the body, into the very centre of the chest, not only without occasioning irritation, but even without producing sufficient sensation to induce consciousness. But when either of these conditions is changed, the state natural to the respiratory process is disturbed; irritation is excited; warning is given that some danger threatens the system; and an effort is made to remove the offending cause. The warning is announced, and an effort is made to remove the danger, by the act of coughing. [CATARRH; BRONCHITIS; PHTHISIS; LUNGS, DISEASES OF; CROUP.]

COUMARIC ACID. [COUMARIN.]

COUMARIN ($C_{18}H_6O_4$). An odoriferous crystalline principle found in the Tonka bean (*Coumarouna odorata*, or *Dipterix odorata*), in the common Melilot (*Melilotus officinalis*), in Woodruff (*Asperula odorata*), and in the sweet-scented Vernal Grass (*Anthoxanthum odoratum*), to which the scent of hay is owing.

To prepare coumarin, coarsely powdered tonka beans are digested for several hours in hot alcohol of 80 per cent. After filtration, the greater part of the alcohol is recovered by distillation, and when the residue begins to appear turbid, water is added, by which means the coumarin is precipitated in a more or less crystalline state. It may be obtained pure and colourless by treating with animal charcoal, and recrystallisation from alcohol.

Coumarin crystallises in rectangular plates. It melts when heated to 122°, and at 518° boils, and sublimes without decomposition. It has an agreeable aromatic odour and a burning taste, is but slightly soluble in cold water, freely so in boiling water or dilute acids. Chlorine, bromine, and iodine act upon it, and yield crystalline compounds.

Nitrocoumarin ($C_{18}H_5(NO_4)O_4$), containing an equivalent of NO_4 in the place of an equivalent of hydrogen, is formed when coumarin is gradually added to cold fuming nitric acid; dilution with water causes the nitrocoumarin to precipitate in snow-white flocks. Hot nitric acid converts it into picric acid.

Nitrocoumarin crystallises from solution in alcohol in white silky needles. It melts at 338°, at a higher temperature sublimes without decomposition, and condenses in pearly crystals.

Coumaric acid ($C_{18}H_8O_6$) is produced when coumarin is boiled in strong solution of potash. Upon diluting with water and adding excess of hydrochloric acid, it is precipitated in the form of lustrous transparent plates.

Coumaric acid is colourless. It has a bitter taste. It is soluble in alcohol, ether, and water. It melts at 374°, and at a higher temperature sublimes, but with partial decomposition. Fused with hydrate of potash, hydrogen escapes, and acetate and salicylate of potash remain.

$$\underbrace{C_{18}H_8O_6}_{\substack{\text{Coumaric}\\ \text{acid.}}} + \underbrace{2KO, HO}_{\substack{\text{Hydrate}\\ \text{of potash.}}} = \underbrace{C_{14}H_5KO_6}_{\substack{\text{Salicylate}\\ \text{of potash.}}} + \underbrace{C_4H_3KO_4}_{\substack{\text{Acetate of}\\ \text{potash.}}} + \underbrace{H_2}_{\substack{\text{Hydrogen}\\ \text{gas.}}}$$

The *coumarates*, containing an equivalent of metal in the place of an equivalent of hydrogen in coumaric acid, are mostly insoluble precipitates, obtained by double decomposition.

COUNCIL, OF THE CHURCH, an assembly of prelates who meet, being duly convoked by the legitimate authority, for the purpose of defining questions of doctrine, or making regulations or canons in matters of discipline. There are various sorts of councils:

1st, General or Œcumenic councils, which are considered as a representative and legislative assembly of the whole Church, and to which all bishops are summoned. A list of these councils will be given hereafter. In the early ages of the Church the general councils were convoked by the Roman emperor; they have been since convoked by the pope, at least for the Western or Roman church. The authority of the general council is considered as binding on the whole Church only in matters of faith, when the canon establishes a dogma which it enjoins all the faithful to believe, under pain of anathema and heresy. In matters of faith the Roman church considers the general council to be infallible; some say, however, only after its canons have been confirmed by the pope. All bishops have a right of attending and voting in the general council; the abbot and generals of monastic orders have also been admitted to vote in most councils by consent of the council. Priests and monks have also attended the councils as theologians and advisers, with a consultative but not a deliberative vote. In the Western church, the pope, or his legate for him, presides in the council. For a council to be legitimate, it is required that all the bishops should be called to it, whether they attend or not, except those who are declared by the church to be schismatic or heretical, and all deliberations should be free and unconstrained.

2nd, National councils, consisting of the bishops of a whole kingdom or state, which can be convoked by the respective sovereigns; but their authority is not considered universal over the whole Church.

3rd. Provincial councils are convoked by the respective metropolitans, with the consent of the sovereign. A bishop may also convoke a diocesan council, with the consent of his superior. (Benedict XIV. 'De Synodo Diocesana.')

The Church of Rome reckons several councils, though not œcumenic, previous to that of Nice; the earliest of which seems to be that held at Jerusalem about the year 50 of our era, which was attended by the apostles Peter, John, James, Paul, and Barnabas, and which is mentioned in the fifteenth chapter of the Acts of the Apostles.

SERIES OF GENERAL OR ŒCUMENIC COUNCILS.

Nice, the Council of, was the first and most important œcumenical council held in the Christian church. It was convened by the emperor Constantine, for the purpose of settling the Arian controversy, after he had in vain attempted to reconcile Arius and Alexander, the leaders of the two opposing parties in that dispute. The council met at Nicæa in Bithynia, in the year 325, and sat probably about two months. It was attended by bishops from nearly every part of the East; but few came from Europe, and scarcely any from Africa, exclusive of Egypt. According to Eusebius, there were more than 250 bishops present, besides presbyters, deacons, and others. Some writers give a larger number. The account generally followed is that of Socrates, Theodoret, and Epiphanius, who state that 318 bishops attended the council. The chief question debated in the council of Nice was the Arian heresy. Eusebius of Cæsarea proposed a creed which the Arian party would have been willing to sign, but it was rejected by the council, and another creed was adopted as embodying the orthodox faith. The most important feature of this creed is the application of the word *consubstantial* (*ὁμοούσιος*) to the Son, to indicate the nature of his union with the Father; this word had been purposely omitted in the creed proposed by Eusebius. The creed agreed upon by the council was signed by all the bishops present, except two. The council excommunicated Arius, who was immediately afterwards banished by the emperor. [ARIUS, in BIOG. DIV.] The time for the celebration of Easter was also fixed by this council, in favour of the practice of the Western church. [EASTER.] It also decided against the schism of Meletius. The only documents which have been handed down to us from this council are its creed, its synodical epistle, and its twenty canons. These canons contain no catalogue of the books of the Bible.

Constantinople, First Council of, convoked by the Emperor Theodosius I., in 382, confirmed the canons of the council of Nice, and established the dogma of the divinity of the Holy Ghost against the attacks of Macedonius. The council consisted of 150 eastern bishops, who decided among other questions that the Bishop of Constantinople should take rank next to the Bishop of Rome. The canons of this council were acknowledged by Damasus, bishop of Rome, and the other western prelates.

Ephesus, Council of, convoked by Theodosius II., in 431, consisted of about 200 bishops, and was attended by the legates of Celestinus, bishop of Rome. It condemned Nestorius. [NESTORIUS, in BIOG. DIV.]

Calchedon, Council of, convoked by the Emperor Marcianus, in 451, consisted of 630 bishops, and the legates of Leo I., bishop of Rome. It condemned the spurious council of Ephesus in 449, which had approved the doctrines of Eutyches and of Dioscorus concerning the two natures in Jesus Christ. [EUTYCHES, in BIOG. DIV.]

Constantinople, Second Council of, convoked by Justinian, in 553, condemned the tenets of Origenes, as well as the doctrines known by the name of the "three chapters." The canons of this council were first disapproved, and afterwards sanctioned, by Vigilius, bishop of Rome. [ORIGENES and VIGILIUS, in BIOG. DIV.]

Constantinople, Third Council of, in 680, convoked by the Emperor Constantine Pogonatus, confirmed the canons of the five previous œcumenical councils, and condemned the tenets of the Monothelites, an offshoot of the Eutychians.

Nice, Second Council of, convoked by the Emperor Constantine, son of Irene, in 787, consisted of above 350 bishops, and was attended by the legates of Pope Adrian I. It condemned the Iconoclasts, and sanctioned the worship of images in the churches. The authority of the above seven councils is acknowledged by the Greek as well as the Latin churches.

Constantinople, Fourth Council of, convoked by the Emperor Basilius, in 859, and attended by the legates of Pope Adrian II., condemned the schism of Photius, and restored Ignatius to the see of Constantinople. [PHOTIUS, in BIOG. DIV.]

Lateran, First Council of, styled the Ninth Œcumenic, was convoked by Pope Calixtus II., in 1123, and consisted only of the Western or Latin bishops, the Greek Church having completely separated itself from that of Rome long before. It made several canons of discipline against simony, clerical concubinage, and the alienation of church property: it placed the incumbents of parishes under the superintendence of the respective bishops, and bestowed indulgences on those who took the cross for the defence of Palestine.

Lateran, Second General Council of, convoked by Innocent II., in 1139, condemned the antipope Anacletus, and his patron Roger, Count of Sicily; condemned also the heresies of Peter of Bruis, and of Arnaldo of Brescia, and made several canons of discipline.

Lateran, Third Council of, convoked by Pope Alexander III., in 1179, after his reconciliation with the Emperor Frederic I., made many canons of discipline and morality; and in its last canon, after anathematising the Cathari, Patarini, Albigenses, and those who afforded them protection, it stated that, although the Church abhors the shedding of blood, it does not refuse the countenance and support of the temporal laws of Christian princes, because the fear of corporal punishment is sometimes efficacious in producing spiritual reformation. The Church, therefore, allows the faithful to take up arms against the anathematised heretics, Cotteraux, Brabançons, and others, who were carrying desolation everywhere, and places those who will fight them under its own especial protection. These Cotteraux, &c., appear to have been a kind of lawless partisans in the pay of turbulent barons, who were mixed up with the sectarian feuds of the times, especially in France. Jews and Saracens were forbidden by the council to possess Christian slaves.

Lateran, Fourth Council of, convoked in 1213 by Pope Innocent III., met in November, 1215, and was attended by the patriarchs of Constantinople and of Jerusalem (Constantinople being then in the hands of the Latins), and by above 400 bishops. It was opened by the pope in person. It sanctioned seventy canons, or decrees, which had been framed by the pope, especially on matters of discipline; and its regulations are often quoted by canonists on questions of marriage, benefices, the election of bishops and abbots, &c. It enforced auricular confession, at least once a year, on all the faithful who have reached the age of discretion, forbidding the confessor to reveal any part of the confession, under pain of deposition and confinement for life in a monastery. It enjoined that, to every cathedral or collegiate church there shall be appointed a teacher of grammar and other arts, for the poor of the laity as well as of the clergy, who shall be taught gratis. In the metropolitan churches there was to be also a professor of theology, to teach and explain to the priests and other churchmen the Holy Scriptures and the care of souls. The council likewise promulgated an exposition or profession of faith, in which the doctrine of transubstantiation was expressly included. The council anathematised all heresies contrary to any part of the said profession; and decreed that heretics, after being condemned by the Church, shall be given over to the secular powers, which are enjoined to drive away from their territories all such heretics; and if the temporal lord neglect to do so, he shall be excommunicated by the bishop; and if, within a year, he does not make his submission, information shall be given to the pope, who will release his vassals from their oath of allegiance, and will give the lands of the refractory feudatory into the hands of an orthodox feudatory, saving the rights of the superior or paramount lord, provided the latter makes no obstacle to the execution of this ordinance. The Gallician theologians, however, reject this canon, as an abuse of power on the part of the council, or rather of the pope who had framed the canon.

(Richard, 'Analyse des Conciles;' 'Concile Quatrième de Lateran.')

Lyon, First Council of, convoked in 1245 by Pope Innocent IV. for the extirpation of heresy and schism, for the affording of assistance to the Christians of Palestine, and also to judge of the charges against the Emperor Frederic II., whose councillor, Thaddeus of Suessa, undertook to defend his master. After listening to his defence, the council excommunicated Frederic; and then the pope, in presence of the council, pronounced sentence of deposition against that emperor. It was not the council that assumed to depose Frederic; nor did Innocent IV., as Bossuet remarks, support his sentence by alleging the sanction of the council to it, as he alleged in other decrees which he issued in the same council; the pope merely says that he pronounced the sentence of deposition in the presence of the holy council assembled. The council also ordered a new crusade for the recovery of the Holy Land, and made provision for the funds required for the purpose.

Lyon, Second Council of, convoked in 1274 by Pope Gregory X., for the object of reforming discipline and the morals of the clergy, for the reunion of the Greek Church, and for the assistance of the Christians of Palestine. The assembly was very numerous, consisting of more than 500 bishops and 1000 inferior dignitaries of the Church, besides the ambassadors of many princes, especially of Michael Comnenus, emperor of Constantinople, who wrote to profess his adherence to the orthodox Roman Catholic faith, and to acknowledge the primacy of the see of Rome. Thirty-eight Greek prelates sent in likewise their act of adhesion. The council made several regulations concerning the election of bishops, and the appointment of parish incumbents, and the administration of church property.

Vienne (in Dauphiny), *Council of*, convoked by Pope Clement V., in 1311, condemned the order of the Templars, and the pope suppressed the order and confiscated their property. [TEMPLARS.] It likewise condemned the so-called Beggars, Fratricelli, and other heretics, and made several regulations of discipline concerning the monasteries and hospitals. It also promulgated a profession of faith concerning the human nature of Jesus Christ, according to the testimony of St. John.

Constance, Council of, was assembled in 1414 at the request of the emperor Sigismund, chiefly to put an end to the great schism, during which John XXIII., Gregory XII., and Benedict XIII., each claimed the rank and office of sovereign pontiff. The Council deposed all three, and elected Ottone, cardinal Colonna, as legitimate pope, by the name of Martin V. It was on this occasion that a canon or decree was passed, asserting the supremacy of a general council over the pope. Gregory and John XXIII. submitted to this decision, the latter after much demurring; but Benedict continued the schism in Spain to the time of his death. The Council was also engaged in the trial of John Huss, who was summoned and appeared before it, and was arrested by order of the Council, notwithstanding a safeguard from the emperor. His doctrines were condemned as heretical, and as he would not retract he was publicly degraded from his priestly office, and then consigned to the civil magistrates, who by order of the emperor had him burnt. For the peculiar opinions of Huss, some of which concerned doctrine, and others discipline, see HUSS, JOHN, in BIOG. DIV. The Council condemned likewise the doctrines of Wycliffe, most of which were identical with those of Huss. Jerome of Prague, a disciple of Huss, having been brought before the Council, first retracted his obnoxious doctrines, but being still kept in prison, as his retractation was not considered to be sincere, he demanded a public audience, at which he declared that he had recanted only through a temporary weakness, and that he persisted in his master's doctrines; upon which he was also condemned to the stake, to which he went with the greatest serenity. Poggio Bracciolini, who was present at the tragical scene, bears full evidence, in his letter to Aretino, to the firmness of the victim; and so does Æneas Sylvius, afterwards Pope Pius II., in his 'Historia Bohemica.'

The Council had promised to occupy itself with a reform of church discipline, which was much wanted in that age; but it did little in that way, having been abruptly dissolved by the new pope Martin V. in April, 1418. The Council of Constance is one of the most notorious in the history of the church, and was one of the most numerous ever assembled. Lenfant has given a full and instructive account of all its proceedings, session after session. ('Histoire du Concile de Constance,' 2 vols. 4to, Amsterdam, 1727.)

The next general council is that of *Basle*, which, on account of its importance in the history of the Church, deserves more particular notice. The council of Basle was convoked by Pope Martin V. in 1430, in conformity to a decree of the council of Constance, session 39, which had provided that a new general council should assemble within five years. Pope Martin appointed Cardinal Julian Cesarini, his legate in Germany, to preside over the council. Soon after, Martin died (February, 1431), and his successor, Eugenius IV., confirmed Cesarini as president of the council. The first session, or meeting, took place in December, 1431, when Cardinal Julian opened the council by an eloquent speech, in which he exhibited the evils of the Church resulting chiefly from the relaxation of its discipline; and, having exhorted the fathers and the clergy in general to give the example of regularity and piety to their flocks, he stated the two great objects of the present council to be, one, the reunion of the Eastern and Western Churches, and the other, an effectual reform of the Church in general in all its members. The council then appointed its various deputations, or committees, to examine at length the matters laid before each of them and make their reports thereon, which were to be taken into consideration by the whole council assembled in session, and there put to the votes.

The second session of the council took place in February, 1432. In the interval between the first and second sessions it became known at Basle that Pope Eugenius intended to dissolve the council as likely to prove troublesome to him if allowed to sit much longer, and that he had actually framed the bull for its dissolution. In consequence of this, the council issed a decree declaring that it held its power immediately from Jesus Christ, the Head of the Church; and that every person, even the pope, was bound to obey its decisions in matters of faith, as well as for the extirpation of schism, and likewise for the reformation of the Church. Meantime the pope had issued his bull of dissolution. Cardinal Julian then wrote two forcible letters to Eugenius, maintaining the rights of the council, and asserting that according to the canons of the council of Constance, by which he himself, Eugenius, held the papal dignity, as successor to Martin V., who had been elected by that council after it had deposed Pope John XXIII., and the other claimants to the papal crown, the pope had no power of dissolving a general council once lawfully convoked and assembled, until that council had performed the task for which it had been convoked. The fathers sent likewise a synodal answer, of the same meaning, to the papal bull, in which they asserted that the pope, although the ministerial head of the Church, was not exalted above the whole mystical body of the Church, as that mystical body, even exclusively of the pope, cannot err in matters of faith, being under the inspiration of the Holy Ghost; whilst the pope, although the head of the Church, might err, as experience showed. The body of the Church represented in the general council had deposed popes who had erred in matters of faith, but no pope had ever assumed to condemn or excommunicate the whole body of the Church.

In the third session, April, 1432, the council summoned Eugenius to revoke the bull of dissolution, and to attend the council in person in three months' time, or to send persons with full powers to represent him.

In the fourth session, June, same year, a safe conduct was given to the Bohemian deputies who proposed to appear before the council to arrange matters for the religious peace of their country. Pope Eugenius being reported ill at the time, the council decreed that in case of his death, the council should not proceed to the election of his successor any where else but in the body of the council. Any other election was declared beforehand to be null and void.

In the fifth session, in August of the same year, three judges were appointed to examine questions of faith. The Bishop of Taranto, sent by Eugenius as his legatee, delivered a high flown speech, exalting the papal authority as the only fit judge of the place and time for the holding of councils, and he stated that as the pope could not then leave Italy, he offered to remove the assembly to any town in the Papal states which the fathers might fix upon. The council replied that to dissolve or remove a council lawfully assembled would be to renew schism in the Church, and would be contrary to charity and the inspiration of the Holy Ghost.

In the sixth session, September, the council decreed that as Pope Eugenius did not make his appearance, he should be declared "contumax" after being cited three times at the gate of the church.

In the seventh session, November, the decree of the fourth session was confirmed, forbidding the cardinals to hold a conclave, in case of the pope's demise, without permission from the council.

In the eighth session, December, a further delay of two months was granted to Eugenius to revoke his bull of dissolution, after which the council would proceed canonically against him. It was also decreed that any other council convoked elsewhere, would be a cabal and a schism, as there could not be more than one general council assembled at a time. The Bohemian deputies arrived at Basle in January, 1433. They laid before the council the demands of their constituents, namely the sacrament "sub utraque" for the laity; that the clergy should have no power over temporal things, and that the word of God should be preached fairly and freely. The council upon this appointed deputies to repair to Bohemia to confer upon these matters on the spot.

In the ninth session, January, 1433, the Emperor Sigismund having by letters patent taken the council and all its members under his especial protection, the council on its part declared that it would protect Sigismund from any arbitrary act of the pope against him.

Tenth session, February, 1433. The council was proceeding to declare Eugenius "contumax," but the emperor and Cardinal Julian interposed, and offered to write to the pope, upon which the council adjourned its proceedings.

Eleventh session, April same year, it was decreed that if the pope henceforth neglected to assemble a general council every ten years, as ordained in the ninth session of the council of Constance, the right of convocation should devolve upon the bishops without the pope's permission. The fathers likewise confirmed the decree of the council of Constance, by which a general council, once assembled, could not be adjourned, transferred or prorogued by the pope without the consent of two-thirds of the members. Meantime Eugenius had sent two legates to the council, with full powers; but the council would not admit them, as the pope had not revoked his bull of dissolution.

Twelfth session, July. The council summoned Pope Eugenius to revoke within two months' time his declaration of transferring the council to another place. It also passed several regulations of discipline, against simony, &c. Eugenius on his part abrogated by a bull the decrees of the council against himself, and declared the council to have been in error when it asserted its superiority above the pope.

Thirteenth session, September. At the request of the Duke of Bavaria another month was allowed to Eugenius before the fathers passed judgment upon him.

Fourteenth session, November. The Emperor Sigismund was present at the council. Three months were granted to Eugenius to revoke all his acts against the council.

Fifteenth session. Eugenius, having at length listened to the mediation of France, Burgundy, and other powers, revoked the bulls which he had launched against the council, and issued another bull according to the form sent to him by that assembly, in which he declared that although he had dissolved the council of Basle lawfully assembled, yet, in order to avoid dissension, he now declared that the council had been lawfully continued since its first beginning, and that he approved of all its decisions, and declared the bull of dissolution to be null and void. He then appointed four cardinals to preside in the council together with Cardinal Julian.

Sixteenth session, February, 1484. The letters of Eugenius were read in full council and presence of the Emperor Sigismund. The papal legates were introduced and incorporated with the council.

Seventeenth session, April. The legates were made to swear to support the dignity of the council, and to observe its decrees as well as those of the Council of Constance, and that their authority should be dependent on that of the council and not coactive with or compulsory upon the council.

Eighteenth session, June. The council confirmed the decrees of the fourth and fifth sessions of the Council of Constance. John, Patriarch of Antioch, read a thesis in favour of the superiority of the general council above the pope.

Nineteenth session, September. Conferences with the ambassadors of John Palæologus, emperor of Constantinople, concerning the projected union of the Eastern and Western churches. Legates appointed by the council to proceed to Constantinople. The council decreed that in every university there shall be professors of Hebrew, Arabic, Greek, and Chaldæan.

Twentieth session, January, 1435. Decrees of reform of church discipline, penalties against concubinarian priests, &c.

Twenty-first session, June. Decree against the "annates," or first fruits, and other payments and fees exacted by the court of Rome. Three years of undisturbed possession of a benefice, obtained by legitimate title, to be considered as affording a prescriptive title to the possessor. Several decrees on public worship and other matters. Pope Eugenius remonstrated strongly against the suppression of the "annates," urging that the council ought at least to make compensation for the support of the Holy See. Cardinal Julian's reply to the pope's remonstrances.

Twenty-second session, October. Condemnation of a book written by an Austin friar, who had ascribed some attributes to the human nature of Christ which properly belonged to his divine nature.

Twenty-third session, March, 1486. Decrees concerning the free election of the pope, his profession of faith, the number of cardinals reduced to twenty-four, &c. All reserved benefices, mandates, and other grants applied by the popes to their own profit, declared null and void.

Twenty-fourth session, April. The legates of Eugenius urged the fathers to fix upon a town where to assemble a new council, in order to meet the Eastern emperor and his retinue and prelates, for the purpose of effecting the reconciliation of the two churches. A congregation was held in consequence, which was attended by 357 prelates, two-thirds of whom voted for the city of Basle, if the Greeks should agree to it, and if not, they proposed Avignon or some town of Savoy. A deputation was sent to Eugenius to entreat him to crown the labours of the present council by the reunion of the Eastern with the Western churches, and inviting him to come in person and expedite the necessary bulls. Eugenius, however, supported by a minority in the council, was for holding a new council in some town of Italy, and many months elapsed in fruitless negotiations upon this subject.

Twenty-fifth session, May, 1437. The council decreed that the œcumenic council for the union of the two churches should sit either at Basle or at Avignon. Most of the fathers did not wish to go to Italy, where they would have been too much in the power of the pope. A division then occurred in the assembly. A minority joined the papal legates, and made a decree by which they assumed the authority and name of a council, and transferred the council to Ferrara. Eugenius hastened to issue a bull which confirmed this decision, and immediately caused a squadron of galleys to be equipped at Venice, to proceed to Constantinople with three papal legates, for the purpose of bringing the emperor and the eastern prelates to Ferrara. The council of Basle, that is to say the majority of that assembly, which had kept together, sent likewise galleys for a similar purpose, but they were too late, and the emperor repaired to Venice with the papal legates on board the Venetian galleys. Cardinal Julian, who was still at Basle, proposed to the council to send a deputation to Venice to receive the emperor on his landing, and, by explaining to him how matters stood, to endeavour to bring him to Basle. The fathers, however, hesitated and lost time. Up to this period the council of Basle is considered by most Roman Catholic theologians, to have been truly œcumenic and legitimate, as Pope Eugenius had solemnly acknowledged it as such since November, 1433, and had since acted in union with it by means of his legates. But some ultramontane divines, and Holstenius among the rest, controvert the authority of the council altogether. Pope Nicholas V. however, who succeeded Eugenius, in his bull beginning "Ut pacis," dated Spoleto, July, 1449, speaks of the council of Basle with respect as a council, and not as a conciliabulum, and Eugenius himself in his letters to his legates in Germany, dated Rome, August, 1446, inserted in the Annals of Raynaldus, speaks of the general councils of Constance and Basle, as being by him acknowledged and venerated, without prejudice, however, to the right and pre-eminence of the Holy See.

The council of Basle, in its twenty-sixth session, July, 1437, again summoned Eugenius to appear before it, and Eugenius answered by a bull for the dissolution of the council, appointing the meeting of a new council, to which he invited all Christian prelates, and forbidding under heavy canonical penalties, the making of any more synodal acts at Basle, after the period of thirty days, which were to be employed in winding up the negotiations with the Bohemian deputies. King Charles VII. of France forbade his bishops to repair to Ferrara.

In their twenty-seventh session, September, the fathers at Basle declared null and void the creation of two cardinals recently made by Eugenius.

In the twenty-eighth session, October, the period assigned to Eugenius for his appearance being expired, the fathers declared him "contumax," and resolved to proceed canonically against him. Eugenius at the same time issued a bull, transferring the council to Ferrara. In his letters to his legates in Germany he speaks of the council of Basle as a legitimate assembly, until the order for transferring it to Ferrara.

In the twenty-ninth session, October, the fathers rejected the bull of transfer to Ferrara, and assigned their reasons for it.

In January, 1438, one Cardinal Nicholas, Eugenius's legate, opened the new council at Ferrara. Cardinal Julian, who still remained at Basle, quitted that town with four other prelates, and joined the council of Ferrara. The council of Basle was declared henceforth null, and all its future acts were declared void. Several theologians date from this epoch the termination of the legality of the council of Basle. That assembly, however, went on holding its sessions for five years longer, and a schism in the Church was the result. The council of Basle deposed Eugenius in 1439, and elected Amadeus VIII. of Savoy, by the name of Felix V. These measures, however, were discountenanced by the great majority of the catholic world; France, England, and Germany disapproved of them. Most of the bishops withdrew from Basle, and their places were filled up by archdeacons, friars, provosts, and doctors, and other churchmen not of episcopal rank. From that period it is impossible to consider the council of Basle any longer as œcumenic. The last session of this self-styled council of Basle was held in May, 1443, when it decreed that within three years a council, or rather a continuation of the council, should be held at Lyon. It, however, met ultimately at Lausanne, in 1449, when Felix having abdicated, the remaining fathers of the council of Basle made their peace with Nicholas V.

In the collection of the Acts of General Councils, handsomely published in Greek and Latin, by order of Pope Paul V., 'Conciliorum generalium Ecclesiæ Catholicæ,' 4 vols. folio, Rome, 1628, the council of Basle is altogether omitted, but that of Constance is inserted. The following writers have treated especially of the council of Basle:—Æneas Sylvius Piccolomini (afterwards Pope Pius V.), who was for a time secretary to the council, in his 'Opera,' which also contain the two celebrated epistles of Cardinal Julian to Pope Eugenius, maintaining the paramount authority of the council; le Père Alexandre, a Dominican, 'Dissertationes de Conciliis Senensi et Basiliensi,' in the eighth volume of his 'Historia Ecclesiastica,' Paris, 1714, and Venice, 1749; Richer 'Responsio Synodalis data Basiliæ, Oratoribus D. Eugenii P. P. IV., in Congregatione Generali III., Non. Septemb. 1432: De Auctoritate cujuslibet Concilii generalis supra Papam et quoslibet Fideles, pars præcipua, et in eam Commentarius,' Coloniæ, 1618; Lenfant, 'Histoire de la Guerre des Hussites et du Concile de Basle,' which refers chiefly to the transactions of the Bohemian schismatics and their negociations with the Council of Basle, on particular points of rite and discipline; Richard 'Analyse de Conciles.'

Ferrara, Council of, was attended by Pope Eugenius, the Emperor John Manuel Palæologus, the patriarch of Constantinople, Mark, archbishop of Ephesus, and about twenty more eastern bishops. The discussions between them and the Latin prelates turned first upon the dogma of the proceeding of the Holy Ghost and the word "filioque" said to have been added by the Latins.

In 1439 the council was transferred to Florence, and the discussions were continued. The two parties effected a reconciliation, excepting Mark of Ephesus, upon the dogma of the Holy Ghost, that of purgatory, and the supremacy of the pope, which the Greeks acknowledged, "saving the privileges and rights of the patriarchs of the East." The act of union was signed by the vicars of the patriarchs of Alexandria, Antioch, and Jerusalem, and by several metropolitans, but it was soon after disavowed by the great body of the Eastern Church. [GREEK CHURCH.] The eastern prelates, about thirty in number, left Florence in August, 1439, to return to their country. After their departure, Pope Eugenius continued the council, although it could no longer be called general, the reunited Eastern Church being no longer represented in it. The fathers of Basle, who had deposed Eugenius, were declared heretical, as well as Felix V., who was declared to be a schismatic antipope. After several other decrees the Council of Florence was closed in April, 1442. The French and other divines do not recognise the authority of the Council of Florence, which however is fully acknowledged at Rome. The same may be said of the following:—

Lateran, the Fifth Council of, was convoked by Pope Julius II., in 1512, to oppose the acts of the pretended council of Pisa, when a certain number of prelates hostile to Julius had assembled under the influence of the king of France, then at variance with the pope. After declaring all the acts of Pisa null and void, and summoning the French prelates to appear at Rome, Pope Julius died in February, 1513, but his successor, Leo X., continued the council, and Louis XII., giving up the "Conciliabulum" of Pisa, sent in his adhesion to the council of Lateran. The French prelates, however, did not attend, under various excuses. The council continued assembled till March, 1517. It chiefly concerned itself with matters of discipline. Among others, it established a general ecclesiastical censorship on all printed books, under pain of excommunication. [Censorship of the Press.] It confirmed the concordat made at Bologna between Pope Leo and Francis I., concerning the sees and benefices of France, and annulled the previous pragmatic sanction promulgated by King Charles VII., conformably to the decrees of the councils of Constance and Basle. The concordat took away from the chapters the right of electing to vacant sees, and gave the nomination to the king, subject to the papal sanction and ordination.

Trent, the Council of, is the last œcumenic council of the Latin church, and is acknowledged as such by the Roman Catholic world, although some of its decrees in matters of discipline are not sanctioned by the laws of many states. [Trent, Council of.]

The principal collections of the acts of the councils are: Labbé and Cossart, 'Sacrorum Conciliorum nova et amplissima Collectio,' with additions by Coleti and Mansi, 31 vols. fol., Florence and Venice, 1759-98; 'Concilia generalia Ecclesiæ Catholicæ Pauli V. Pont. Max. auctoritate edita,' 4 vols. fol. Rome, 1628; 'Concilia Generalia,' edita a T. Merlino, 2 vols. fol., Cologne, 1530; 'Concilia Omnia, tam generalia quam particularia,' a Petro Crabbe, 2 vols. fol., Cologne, 1538-40; 'Collectio Regia maxima Conciliorum, seu Acta Conciliorum et Epistolæ Decretales, ac Constitutiones Summorum Pontificum ab anno Christi 34 ad 1714, studio Joh. Harduini, Soc. Jesu; cum novis indicibus,' 12 vols. fol., Paris, 1714-15.

There are also collections of national councils: 'Collectio Conciliorum Hispaniæ, diligentia Garsiæ Loaisa elaborata,' fol., Madrid, 1593; 'Concilia Magnæ Britanniæ et Hiberniæ a Synodo Verolamiensi, A.D. 446 ad Londinense, A.D. 1717, a D. Wilkins collecta,' 4 vols. fol., 1737; 'Sacra Concilia Ecclesiæ Romano-Catholicæ in Regno Hungariæ celebrata, ab anno 1016 ad 1734,' fol., Vienna, 1742; 'Concilia antiqua Galliæ, cum Epistolis Pontificum, Principum Constitutionibus, et aliis Gallicanæ rei Ecclesiasticæ monimentis, Opera et Studio T. Sirmondi,' 3 vols. fol., Paris, 1629; 'Collectio maxima Conciliorum omnium Hispaniæ et novi Orbis, cura et studio Jos. Saenz de Aguirre, editio altera novis additionibus aucta a Jos. Catalano, cum indicibus,' 6 vols. fol., Rome, 1753; 'Conciles de Toulouse, Béziers, et Narbonne, ensemble les ordonnances du Comte Raimond contre les Albigeois, par Arnaud Sorbin, D.D.,' 8vo., Paris, 1569; 'Atti dell' assemblea degli Arcivescovi e Vescovi della Toscana tenuta in Firenze, l'anno 1787,' 4to., Firenze, 1787; 'Atti e decreti del Concilio Diocesano di Pistoja dell' anno 1786,' 4to. Firenze, 1788; 'Salmon, Traité de l'etude des Conciles et de leurs Collections,' Paris, 1724.

Some of the old Spanish councils are very important, such as the Council of Iliberis, 303, which concerned itself chiefly with the morals of the faithful, exposed as they were to the bad example of their heathen countrymen. Its canons, to the number of eighty, have come down to us, which is not the case with most of the previous councils. Several of the councils of Toledo are also very important for the elucidation of Church history and controversy, especially on questions of discipline.

The Greek or Eastern Church, since its separation from Rome, has held its own general councils or synods under the presidency of the œcumenic patriarchs of Constantinople. [Greek Church; Russian Church.]

The Protestant and Reformed Churches have also held their councils or synods, such as Dort, Synod of. The Synod of Emden, in 1571, and that of Sandomir, for the Protestant churches of Poland; the general assemblies of the Scottish Church, and the convocations of the Church of England, are also a sort of national councils; but the Protestants in general do not admit the divine inspiration and consequent infallibility of the councils, whether general or national, though they acknowledge the doctrines propounded by the first two œcumenic councils of Nice and Constantinople.

COUNCILLORS. [Corporations; Municipal Corporations.]

COUNSEL, an abbreviation of counsellor, by which in England is understood a barrister. The phrase includes, of course, serjeants, Queen's counsel, and by courtesy comprehends those who, having kept twelve terms at one of the inns of court, have been permitted to practise under the bar. [Barrister.] The word has no plural number, and is used to denote either one or more counsel. The duty of counsel is to give advice in questions of law, and to manage causes for clients. They are styled common law, equity, or chamber counsel, according to the nature of the business they transact. They are supposed to plead gratuitously. [Advocate.] In the words of Mr. Justice Bayley, 1 Chit. R. 351, "they are to be paid beforehand, because they are not to be left to the chance whether they shall ultimately get their fees or not, and it is for the purpose of promoting the honour and integrity of the bar that it is expected all their fees should be paid when their briefs are delivered. That is the reason why they are not permitted to maintain an action for their fees." Counsel may be retained generally, that is, to advocate any cause in which the retaining party may be engaged, or specially with reference to a pending cause; and generally speaking, it is not optional for counsel to refuse a retainer; there are certain rules, however, by which their practice is regulated.

Counsel in a cause have the privilege of enforcing anything which is contained in their instructions and is pertinent to the matter in question, and are not bound to inquire whether it be true or false; they are also at liberty to make fair comments on the evidence adduced.

Formerly, in cases of felony, counsel for the prisoner were not allowed to address the jury on his behalf; they might, however, examine and cross-examine the witnesses, and argue points of law; but now by stat. 6 & 7 Wm. IV. c. 114, all persons tried for felony may make full answer and defence by counsel.

Counsel are punishable by stat. West. 1. 3 Ed. I., c. 28, for deceit or collusion, and, it is said, are so far under the jurisdiction of the judges, that in the event of malpractice they may be prohibited from addressing the court. They are certainly bound by the rules established by each court for the regulation of its own practice; and for professional or other misconduct may be disbarred by the inn of court to which they belong. (Blackst. 'Comm.,' Mr. Kerr's ed., v. iii. p. 28.)

COUNT, through the French word *comte*, from the Latin *comes, comitis*, meaning companion. Considered in its original acceptation, this word might be translated by assessor, an officer who, during the Roman republic, was given as an assistant to the proconsuls or the proprætors sent out to govern the provinces. Cicero speaks of these comites in several passages of his works. Dion Cassius states that Augustus Cæsar called by that name all the officers of his imperial household. These comites pronounced judgment on all matters referred to them by the emperor, and their judgments had the same authority as the Senatus Consulta. The council of state instituted by Napoleon I. gives a very exact idea of the constitution of that court tribunal. Like the council of state, the latter was invested with judicial, legislative, and executive power. The emperors of the East followed the example of those of the West, with this difference only, that the comites created by Augustus and his successors were the counsellors of the emperor, and the title belonged to the office and not to the person; whilst at the court of Constantinople it was quite the contrary. The nomenclature of these counts fills a considerable place in the Glossary of Ducange. The *comes marcarum*, counts of the frontiers, which were formerly called *marches* (a denomination still in use in the papal states), took subsequently the title of *marquis*; an innovation which raised long and serious discussions among the learned in feudal right and court etiquette.

Under the first two races of the Frank kings, the counts were, as under the lower empire, officers of various degrees. The count of the palace was the first dignity in the state, after the *maire* of the palace. He presided in the court royal when the prince was absent, and possessed sovereign jurisdiction. He also exercised a great influence in the nomination of the king's delegates, who, under the title of counts, administered the provinces. A count had the government of a small district, often limited to a town and its dependencies. He was at the same time a judge, a civil administrator, and a military commander. In case of war, he led in person the contingent of his county to the army. The learned Dutillet, in his 'Recueil des Rois de France, de leur Couronne, et Maison,' &c., expatiates on the functions of ancient counts. With the progress of time, the counts, as well as the other officers appointed to govern the provinces, the towns, and the frontiers, succeeded in rendering their places hereditary, and in making themselves sovereign masters of the districts of which they had only been created removeable and revocable administrators. At first they contented themselves with securing the reversion to their sons, then to their collateral heirs, and finally they declared those places hereditary for ever, under Hugh Capet, the son of Robert, count of Paris, who himself only obtained the throne partly in consequence of that concession. It was feudalism that introduced inheritance instead of election as a permanent rule in political successions. The supreme chief of the ancient Franks, *koning* (Lat. *rex*), was a magistrate, and as a magistrate he was elected, although always from the same family. The inferior chiefs, *heri-zoghe, graven, rakhen-burghe*[*] (Lat. *duces, comites, judices*), were also elected.

The term "count" is now become in France a mere title, conferring no political importance. In the papal states, as well as in those of

---

[*] *Heri-zoghe*, in its proper acceptation, means *leader of an army*, from the word *heer*, army, and the verb *siehen*, to lead. *Grave, graf, gheref*, means, in all the Germanic dialects, the authority of a secondary magistrate. *Rakhen-burghe* means notable persons; they are employed as judges and guardians of public order.

Austria, it may be bought with sums of money not at all considerable; and in the other monarchical states of the continent, it is granted as a mark of imperial or royal favour.

The title of *earl*, or, as it was often rendered in Latin, *comes*, companion, is of very high antiquity in England, being well known to the Saxons under the name of *alderman*, that is to say *elder-man*, and also *shireman*, because each of them had the government of a distinct *shire*, or, as it is now generally called, *county*. The sheriff, under his latinised name, is called vice-comes, or viscount, which term [VISCOUNT] is now one of the titles of rank in the British peerage. The term count seems not to have been used in England as a title of honour, though the wives of earls from a very early period have been addressed by the title of countess. The king, in mentioning an earl in any writ or commission, usually styles him "trusty and well-beloved cousin," a peculiarity at least as ancient as the reign of Edward III.

COUNT. [DECLARATION; PLEADING.]

COUNTER-APPROACH is the term applied in fortification to any small work thrown up by the besieged to look into or enfilade any of the besiegers' approaches. As its name indicates, it is generally made by running out a trench from one of the outworks to some advantageous rising ground in its vicinity, or to such a position that a battery formed in it may enfilade some of the enemy's boyaux of communication which have been directed clear of the main works. By these means, an active, vigorous, and energetic defender may prolong his defence considerably, as each counter-approach entails much loss of time to a besieger, either in taking it or making fresh communications. In no siege, perhaps, in history has this plan been followed out to so great an extent and with such great success as at Sebastopol: there a force as large, and for a time much larger, than the besiegers, with an unlimited supply of *materiel*, was enabled to push out counter-approaches as fast as the allies could advance their trenches; and thus the besiegers were every now and then surprised and stopped by finding works rapidly constructed and armed on their flank and almost in their rear, entailing great loss of time while the works were extended to the flank and fresh approaches made to take these counter-approaches. Thus was it with the Mamelon, and with what were called the White Works, which cost the French many thousands of lives to take.

COUNTER-ARCHED REVETMENTS, or *Revêtments en Décharge.* The simple or plain revetment consists, as described under BASTION, of a retaining wall of masonry, strengthened at intervals by counterforts, supporting the earth of the rampart which rests against it; in the counter-arched revetment the mass of earth does not, however, rest against the main wall, which is therefore made for the escarp only 5 feet, and counterscarp only 3 feet, thick; and the counter-forts, 5 feet thick and 16 feet from centre to centre, extend about 8 feet back, and rising about 7 feet above the foot of the revetment, are then covered and connected by arches turned from one to the other, which support the earth of the parapet and thereby form a bomb-proof cover, communication being obtained along the whole extent by openings cut in the piers. With loopholes cut in the front wall, counter-arched revetments are further useful in affording a defence for the ditch by a low musketry fire. The earth of the rampart is retained either by arches turned from end to end of the counterforts with their concavity to the front wall, or by a flat wall connecting the piers, or without anything at all by the earth being allowed to assume its natural slope. Hence a further advantage of the counter-arched revetment is, that the besieger, after breaching the front wall, must break through these counter-arches by breaching or mining the piers before he can make a practicable breach. To make the destruction of the piers more difficult, and to hinder the earth falling to a slope, even when the outer revetment is breached, the counterforts are connected in portions of Carnot's system by two walls 1 foot 6 inches thick placed at 11 and 18 feet from the back of the escarp, and arched convex towards the rear. The compartments formed by this network of walls are then filled with earth. [REVETMENT.]

COUNTERFORT, an addition to the thickness of a quay or of an abutment wall, made for the purpose of increasing the dynamical resistance of the latter; and a *counterfort* differs from a *buttress* in this respect, that the former is placed on the inside of the wall, where it is hidden by the earthwork or other backing; whereas the latter is apparent, and is often made to form part of the architectural character of a building. The philosophical principles to be observed with either of these portions of a building are however the same, and they may be stated to be, that they should distribute the effort over the greatest possible area, and also as far as possible decompose its action, in such a manner as to bring it ultimately upon the base of the additional structures, which can more easily be rendered perfect than the base of the whole wall. Counterforts, when used to strengthen the abutments of a bridge, must present a moment of dynamical resistance which shall be more than sufficient to compensate for the deficiencies of the abutment itself; and this may be ascertained by supposing that the mass of the counterfort is applied in a thin sheet along the inner side of the wall, or, in other words, that the mass of the wall is increased by the whole mass of the counterfort. But evidently this is an unfavourable, whilst it is a safe mode of calculation; for it leaves entirely out of account the influence of the leverage of the projection. When counterforts are applied to the inner faces of quay walls they act by splitting up into portions, as it were the effort of the earthwork behind them nearly as much as they do by increasing the dynamical resistance of the walls themselves. Great precautions must be adopted in building such counterforts to ensure the sound binding together of the masonry of the respective parts of the structure.

COUNTER-FORTS, in military architecture, are buttresses of brick or stone built against the revetment walls, by which the outward pressure of the rampart, or of the natural ground on the opposite side of the ditch, is resisted. The rectangular portions at N and M, *fig.* 2, BASTION, are counter-forts so situated. They are intended to increase the strength of such walls, and are formed between them and the earth which the walls retain. Their depth is usually equal to the mean thickness of the revetment, and they are placed at intervals of about 18 feet from each other, along the walls. They are sometimes connected together by counter-arches. [REVETMENT.]

COUNTER-GUARDS are outworks occasionally constructed on the exterior of the bastions or ravelins of a fortress in order to retard the formation of a breach in either of those works.

The counter-guard is in general merely a line of rampart surmounted by a parapet, and broken in direction so as to form two faces parallel to those of the work which it covers; it has less relief than the interior work, in order that the fire from the latter may pass over it, and when taken may not afford the enemy in any lodgment which he may form in it the power of seeing into the main works. Its breadth in rear of the parapet should not exceed about 18 feet, that, while there may be room for the defenders, the enemy may not have sufficient space for the establishment of a battery on its *terreplein*; and consequently, that he may not be able to breach the bastion or ravelin till, by mining or otherwise, he has detroyed the counter-guard.

When counter-guards are constructed in front both of a bastion and of the collateral ravelin, the interval between their extremities unavoidably leaves a face of one of these works exposed; and, as a breach in the former would be more fatal to the defenders than one in the latter work, the lengths of the counter-guards must be determined by the condition that the exposed face be that of the ravelin.

What are called counter-guards in the second and third systems of Vauban are, properly, bastions detached from the line of rampart called the enceinte. [See the work marked V, in *fig.* 3, BASTION.]

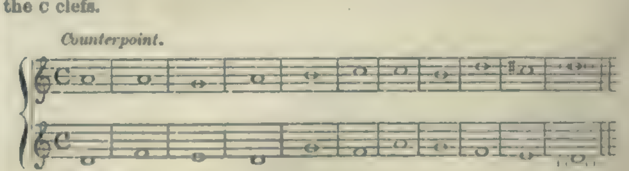
Counter-guards always, however, have the disadvantage, when taken, of providing a safe large retired *place d'armes* in their ditches, where the attacking officer may collect his assaulting column close to the breach.

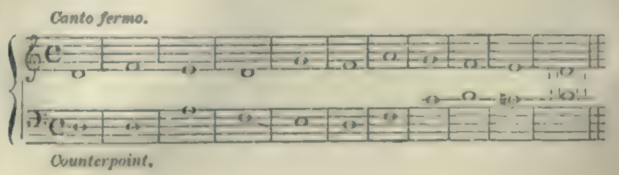
COUNTERMINE. [MINES, MILITARY.]

COUNTERPART. [DEED.]

COUNTERPOINT, in music (*contrapunctum*), is a term now synonymous with harmony [HARMONY], and nearly so with composition; but the latter implies more of invention, of imagination, particularly as relates to melody, than counterpoint imports. Counterpoint in its literal and strict sense signifies *point against point.* In the infancy of harmony, musical notes or signs were simple points, or dots, and in compositions in two or more parts were placed on staves, over, or against, each other. Subsequently, the term was applied to the parts added to a given melody, such melody taking the name of *cantus-firmus, canto-fermo*, or plain-song. [PLAIN-SONG.] Viewing it in this sense, the Padre Martini wrote his very elaborate and justly-celebrated 'Saggio di Contrappunto sopra il Canto-Fermo' (1774), a work to which we refer every student who wishes to enter deeply into the subject. But Zarlino, in his 'Institutione Harmoniche' (1589), ranks counterpoint as the principal part ("*soggetto principale*") in airs, &c., written in two parts. And many writers consider the word as applying generally to composition in parts, among whom are the learned Dr. Pepusch, the acute Spanish jesuit Eximeno, the industrious Dr. Lichtenthal, &c.; so unstable is musical language, so ill defined are musical terms!

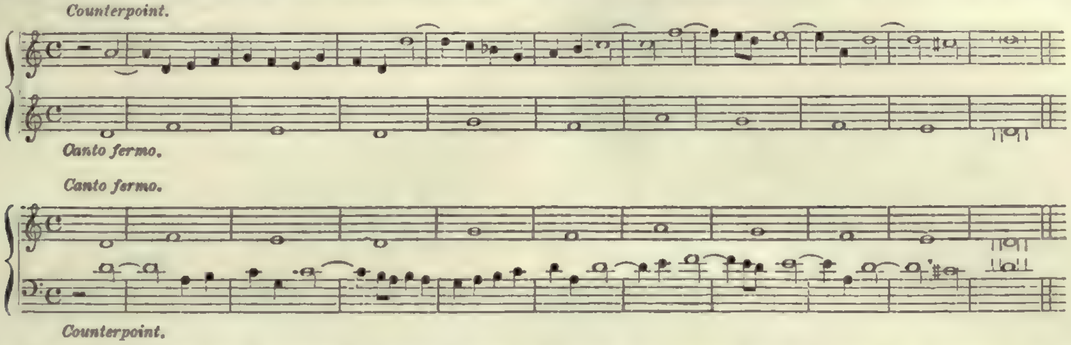
Counterpoint is divided into *Simple, Florid*, or *Figurate*, and *Double*. Simple counterpoint is a composition in two or more parts, the notes of each part being equal in value to those of the corresponding part, or parts, and concords. Johann Fux, Kapellmeister to the emperor Charles VI., in his 'Gradus ad Parnassum' (1725), furnishes us with the following examples of this species, calling one part *cantus firmus*, or the *canto fermo*, the other *contrapunctum*, or counterpoint, and taking each in turn as the melody. We have here substituted the treble for the C clefs.



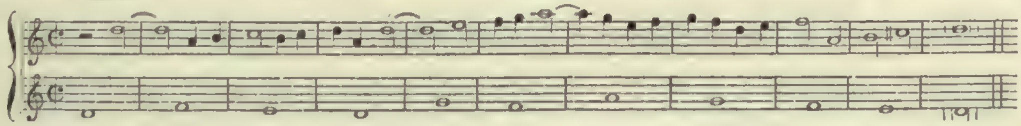


In *Florid Counterpoint* two or more notes are written against each note of the subject, or *canto fermo*, and discords are admissible. Examples from Fux.

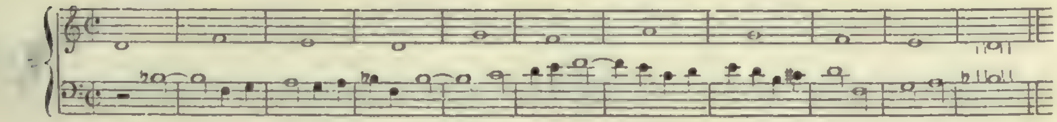
Double Counterpoint, says the German theorist whose examples we have quoted, "is a species of composition in which any of the parts may be transposed into the tenth above or below, omitting some notes, the subject remaining stationary." Or, in other words, it is an inversion of the parts, so that the base may become the subject, the subject the base, &c., thus producing new melodies and new harmonies, "in an artificial and wonderful manner," adds Pedro Cerone, who seems to have been quite delighted with the contrivance; at a period, however (1613), when subtleties of all kinds were more valued than in the present day. Fux gives the subjoined examples of double counterpoint, from which it will be seen that this is little more than an extension of florid counterpoint. In the first example the *canto fermo* is the base, the counterpoint the treble. In the second, the *canto fermo* is the upper part, while the counterpoint is transposed a tenth lower, and becomes the base. In the third, the *canto fermo* and counterpoint remain as in the first example, while the latter, transposed a tenth lower, is adopted as a base, as in Ex. 2; and thus is formed a composition in three parts.



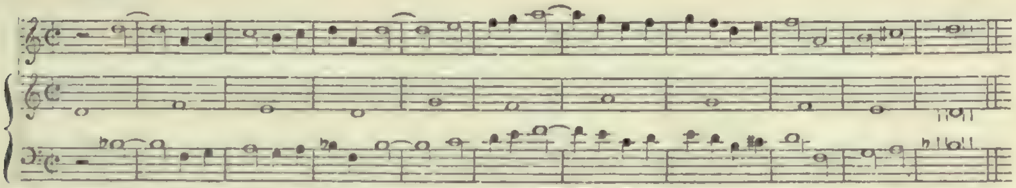
Ex. 1.



Ex. 2.



Ex. 3.



The study of Counterpoint is necessary as part of the education of a good musician, though now much neglected; it has, nevertheless, been sometimes carried to such a length as to become pure pedantry. For the principal rules of Counterpoint,—and also for some brief remarks on the question, "whether the art of writing in parts," was understood by the ancients, see HARMONY.

COUNTERPOISE is, generally, a mass of brass or iron so disposed as to keep a part of some instrument or machine *in equilibrio*.

The instruments employed in practical astronomy are generally mounted so that their centres of gravity are supported, in which case they require no counterpoise; but a reflecting circle, for example, when placed in any position except one which is horizontal, has its centre of gravity on one side of the pillar which supports it; and a mass of brass, so connected with the axis of the circle as to be always on the side of the pillar which is opposite the latter, serves the purpose of keeping the instrument steady.

A transit instrument, or a mural circle of considerable magnitude and weight, whose pivots would press heavily on their supports, is sometimes provided with counterpoises, one for each point which is to be relieved; this is applied at one end of a lever which is supported by the pillar or stand of the instrument, the other end being connected, near the pivot, with the axle; and thus the pressure is diminished or wholly removed.

A bridge which is capable of being turned on horizontal joints at one of its extremities [DRAWBRIDGE] usually has its weight relieved, or almost wholly removed, by a counterpoise, so that the machinery employed to raise it has little except the resistance arising from friction to overcome. The counterpoise is at one extremity of a chain, which passes over a pulley at the top of a pillar, and is attached at the other extremity to some part of the bridge.

Now, since a drawbridge, in being raised or lowered, exerts on the suspending chains a strain which increases as the bridge declines more from a vertical position, it is necessary, in order that this strain may be always *in equilibrio* with the constant weight serving as a counterpoise, that the latter should move on a surface whose figure is determined consistently with that condition. The rules for the resolution of forces give expressions for the strains to which the two parts of the chain are subject in the directions of their lengths; and, making these equal to one another, there is obtained an equation which may be shown to be that of an epitrochoid; such, consequently, is the figure which should be given to the surface on which the counterpoise is to slide. It should be observed that, in the investigation, the effective weight of the drawbridge is not its absolute weight (acting at the centre of gravity); but is equal to this latter weight diminished in the inverse ratio of the distances of the fulcrum, or joint, from the centre of gravity and from the point at which the chain is attached to the bridge, generally the opposite extremity of the latter.

If the pulley over which the chain passes is close to the elevated extremity of the bridge when the latter is in a vertical position, the length of the chain will, of course, be equal to the diagonal of a square of which the length of the bridge is one side; then, a circle whose centre corresponds to the joint of the drawbridge, and whose radius is the whole length of the chain, being supposed to revolve on the circumference of a fixed circle of equal radius; a point supposed to be on the produced radius of the revolving circle, or epicycle, at a distance from its centre equal to the difference between twice the length of the radius, or chain, and the length of the bridge will, by revolving with the epicycle, describe the required curve.

The great telescope of Lord Rosse, at Parsonstown, Ireland, turns upon a joint at its lower extremity; and, being intended to decline from a vertical position both towards the north and the south, it is provided with two counterpoises, in order to facilitate its elevation or depression. One of these weights is on a chain which is attached, at one extremity, to a point near the object end of the telescope, and, at the other, to a fixed point at the top of the wall; this point being so situated that, in elevating the telescope, the weight descends, and describes, by its gravity, a circular arc coinciding nearly with the proper epitrochoid. The other weight is at the end of a lever projecting horizontally, from the lower extremity of the telescope, when the latter is in a vertical position; and then, consequently, it acts with the greatest power; its action diminishes, by the lever being elevated or depressed, as the telescope declines from the vertical towards the north or south.

COUNTERSCARP, is that side of the ditch, about a fortress, which is opposite to the ramparts. The part which is in front of the salient angle of a work is in the form (on the plan) of a circular arc having the vertex of that angle as a centre; and, if the ditch be that of an outwork, the direction of the counterscarp is generally parallel to the rampart; the counterscarp of the main ditch is in the direction of a line which is a tangent drawn to the arc from the shoulder of the collateral bastion. [See the lines above F G, G E, *fig.* 1. Bastion.] This is intended, since the length of the flank is greater than the breadth of the ditch at the said angle, to allow the whole fire of the flank to be directed along the main ditch; and Cormontaingne suggests that the tangent should be drawn from the interior side of the parapet at the shoulder angle, in order that the fire of the man stationed there may more accurately graze the wall of the counterscarp.

In most systems of fortification the counterscarp is retained by a vertical wall of masonry, similar to that of the escarp [Escarp], in order to render the descent of the enemy into the ditch a difficult operation, requiring mining or other operation to destroy the wall, and thereby entailing delay: the defence of the covered way is also thereby prolonged, since the enemy who may have entered it at one place is unable to spread along it on account of the traverses which are constructed across it. Carnot, however, recommends that the counterscarp side of the ditch should be formed in a gentle slope rising from the bottom to the level of the natural ground, in order that the garrison may with facility make those great sorties which he considers as one of the most powerful means of defence.

COUNTERVALLATION, a chain of redoubts executed about a fortress in order to prevent the sorties of the garrison: the works are generally unconnected with each other, but sometimes they are united by a continuous line of parapet. It has happened, during the continuance of a siege or blockade, that the investing corps has been menaced by an army coming up to relieve the fortress; in which case, when it is intended to act on the defensive without abandoning the siege, a chain of redoubts is constructed to strengthen that corps on the exterior: this is called a circumvallation; and originally, like the interior chain, it entirely surrounded the fortress.

According to Thucydides, the town of Platæa, when besieged by the Lacedæmonians, was surrounded by a line of palisades to prevent the egress of the garrison; and subsequently a circumvallation was added. At the siege of Alesia, the countervallation executed by Cæsar consisted of a rampart of earth, 12 feet high, which was surmounted by a parapet, probably of stakes, and by turrets, at the distance of 80 feet from each other. A triple ditch was formed between this line and the town. The Roman army was encamped beyond the line, and enclosed by a circumvallation of similar form; the latter was 14 miles in circumference. It is related in the continuation of the history written by William of Tyre, that, at the siege of Acre by Richard I. of England, the defenders made a sortie, and having forced the agger, began to plunder the camp; and it is added, that Saladin, being in the neighbourhood with an army, made a night attack on the lines: these circumstances sufficiently indicate that both countervallations and circumvallations were then in use.

The long duration of ancient sieges rendered such works indispensable; but the use of artillery having greatly abridged the time to which the defence of a fortified place can be extended, they have become of less importance, and, in fact, it is only when the garrison is strong and the quarters of the besieging army are separated by the obstacles of the ground, that any works are considered necessary; and, in this case, instead of continuous lines of palisades and high towers of wood, a few simple redoubts and breast-works of earth are constructed at intervals. In general, the besiegers are protected by an army of observation in the field, when any effort on the part of the enemy to raise the siege is apprehended.

The siege of Sebastopol may seem at first sight to contradict the statement of works of circumvallation being little used in modern sieges, for there numerous and powerful works were thrown up to protect the besiegers' army from the attacks of the besieged, and indeed the want of them was felt at Inkermann; but it must be remembered that this could hardly be termed a siege in the strict sense of the word, but rather the attempt of one army to dislodge another equally powerful and, at times, more numerous opponent, from a strongly fortified position with supplies and *matériel* of every description close at hand. In consequence of which, and of the non-investment of the place, while the whole disposable force of the allies was occupied in carrying on the attack, works were necessary to protect their flanks and rear from the sudden sorties of the disposable Russian forces on any weak and unguarded points.

COUNTY. [Shire.]

COUNTY COURTS. The whole jurisdiction in civil causes of the old *schyremote*, or County Court, has been transferred to the new County Courts, first established for the recovery of claims not exceeding 20*l.* in amount, in 1846, but whose jurisdiction has since been considerably extended.

These tribunals were intended, not only to bring justice to every man's door, but also to supply the place of a great variety of inferior courts, established in different localities by as many different Acts of Parliament, obtained for that purpose. These Courts of Requests, or Courts of Conscience, as they were called, were intended solely for the recovery of small debts, and were consequently abolished when the new County Courts were established.

The County Court may entertain suits for the recovery of all debts, damages, and demands, legacies, and balances of partnership accounts, where the sum sued for does not exceed 50*l.* If the parties consent in writing, claims to any amount may be determined; but the court has no jurisdiction (unless the parties consent in writing) in any action in which the *title* to real property or in which the *validity* of any bequest under a will or settlement, may come in question; nor in any action for a malicious prosecution, for libel or slander, or seduction.

The crown may sue in this court for duties and penalties not exceeding one hundred pounds, the judgment in such cases being final. An action again may be brought in it against a custom-house officer, in respect of any illegal seizure of vessels or goods, where the damages do not exceed fifty pounds; but in this case there is an appeal, as in an ordinary action (16 & 17 Vict. c. 107). Questions between the crown and any party liable for Succession Duties (not exceeding fifty pounds) may also be determined in this court; the decision of the judge in such cases also being final (16 & 17 Vict. c. 51).

The County Courts are essentially *local* courts, for to give jurisdiction the defendant must reside within the district of the court, at the time of the action being brought. By leave of the court an action may be brought where the cause thereof arose within its district, in cases in which the defendant has dwelt or carried on business in such district within six months. The court has also jurisdiction to give a landlord possession of premises of which the rent does not exceed 50*l.*, and no fine has been paid, where the tenant's term has determined, or he has received notice to quit, or where the rent is half a year in arrear.

Its jurisdiction in testamentary matters is explained elsewhere. [Probate.] The County Court has an exclusive jurisdiction in determining the claims and disputes of the members and officers of Friendly Societies, Industrial and Provident Societies, and of Literary and Scientific Institutions (18 & 19 Vict. c. 63, s. 41; 15 & 16 Vict. c. 31, s. 8, the Literary and Scientific Institutions Act, 1854), and in the appointment of trustees to, and the regulation of, all charities within the district of the court, of which the gross annual revenue does not exceed 30*l.* [Charities.]

A suit is begun by the entry of a plaint at the office of the court, which sets out the names of the plaintiff and defendant, and the nature of the action. Thereupon a summons is issued, a copy of which is served on the defendant by one of the bailiffs of the court, requiring the defendant to appear; which he must do at the court to which he is summoned, or have judgment given against him. If defence is made, the matter in dispute is, on the trial, inquired into, and disposed of summarily by the judge; who is to decide all questions, as well of fact as of law, unless one or other of the parties has demanded a jury for the trial of matters of fact: for in actions for sums above 5*l.*, a jury of five may be obtained as of right; in this case the facts are to be tried by the jury.

In actions for more than 20*l.*, an appeal lies to either of the superior courts of law at Westminster, against the decision of the judge in matter of law, or in the reception or rejection of evidence. No appeal lies against his decision in matters of fact.

The court, which is held once a month, is a court of record. On its judgment execution may be issued against the goods of the unsuccessful party. If he has no goods, but has the means of paying, and refuses to do so, he may be punished, after inquiry into his circumstances, by imprisonment for a period not exceeding forty days; or the judgment (if for more than 20*l.*) may be removed into one of the superior courts, and enforced there by the ordinary process of execution.

To encourage suitors to resort to this court, the plaintiff in the superior courts (in suits in which they have concurrent jurisdiction) does not in general obtain costs in actions of *contract* where he recovers less than 20*l.*, and in actions of *tort* where he recovers no more than 5*l.*, unless the judge who tries the cause certifies for costs, or it appears that there was sufficient reason for bringing the action in the superior court.

Previously to the establishment of the County Courts, the Courts of Bankruptcy had, under the 'Protection Acts,' jurisdiction to grant to any person who was *a trader* owing less than 300*l.* in all, or who was *not a trader* within the bankrupt laws, protection from all process. This jurisdiction was, by the statute 10 & 11 Vict. c. 102, vested in the County Court, and the Court for the Relief of Insolvent Debtors, in London. [Protection Acts.] In the County Court, also, may now be tried all actions of replevin. [Replevin.] The judge has also power to grant a warrant for the arrest of an absconding debtor, and by statute 17 & 18 Vict. c. 104, to direct a vessel which has caused injury by collision or otherwise to another vessel to be detained until satisfaction is made for the injury, or security given to abide the event of legal proceedings.

The nature and jurisdiction of this court have been described thus fully, in consequence not only of the recent erection of these tribunals, but of the extent and variety of the powers vested in them, and the important position they have taken in the estimation of the people. (Blackstone's 'Commentaries,' Dr. Kerr's edit., vol. viii., p. 38.)

COUNTY RATE. County rates are taxes levied for the purpose of defraying the expenses to which counties are liable. They are levied either under the authority of acts of parliament, or on the principle that as duties are imposed upon a county there must be a power to raise the money for the costs incurred in the performance of such duties.

The ancient purposes of the county rate "were to provide for the maintenance of the county courts, for the expenses incidental to the county police, and the civil and military government of the county; for the payment of common judicial fines; for the maintenance of places of defence (sometimes, however, provided by a separate tax common to counties and to other districts, called *burgbote*), prisons, gaols, bridges (when these were not provided for by a separate tax common to counties and to other districts, called *brukbote*), and occasionally high roads, rivers, and watercourses, and for the payment of the wages of the knights of the shire. Additions to these purposes, some occasional and some permanent, were made from time to time by statutes. The king's aids, taxes, and subsidies were usually first imposed on the county, and collected as if they had been county taxes. But the first statute defining any of its present purposes (though now repealed as to the mode it prescribes for imposing the tax) was passed in the 22 Henry VIII. From that time up to the present new purposes have constantly been added, and new and distinct rates were constantly created for purposes of comparatively little importance, and to raise sums of money quite insignificant in amount." ('Report on Local Taxation,' by the Poor Law Commissioners.)

The assessment and collection of separate county rates was not only very inconvenient and troublesome, but so expensive that the charge of collection and assessment frequently exceeded the sum rated. For remedying this evil the 12 Geo. II. c. 29, was passed, whereby justices of the peace at general or quarter sessions were enabled to make a general rate to answer the purpose of the distinct rates previously leviable under various acts of parliament for the purposes of bridges, gaols, prisons, and houses of correction, such rate to be assessed upon every town, parish, and place within the county, to be collected by the churchwardens and overseers, along with the poor rates of every parish, and paid over to the high constable of hundreds, by them to treasurers appointed by the justices, and again by them to whomsoever the justices should direct.

Various acts amending the above statute were passed, but the whole law was consolidated, and the former statutes repealed, by the 15 & 16 Vict. c. 81. Under that statute, courts of quarter sessions appoint a committee of justices for the purpose of preparing and altering from time to time, a basis or standard for fair and equal county rates, founded on the value of property rateable to the relief of the poor, returns for that purpose being laid before the committee by overseers and other parish officers. The basis, being approved by the committee, is laid before the court of quarter sessions, who, after public notice, may confirm it with or without amendment, or refer it back to the committee. Overseers have a right of appeal against the basis on the ground of inequality. The basis being settled, the court of quarter sessions from time to time directs a county rate to be made according to this basis, for all the purposes to which such rate is made liable by law, expressing the amount on each parish, and against this rate parishes and individuals may appeal. The rate is collected by the overseers under precepts sent by the justices to the guardians of every union, or to the high constable of a hundred, and the amount is paid over to the county treasurer (or by the 21 & 22 Vict. c. 33, to the divisional treasurer), who is required to publish an annual abstract of his receipts and expenditure. This act extends to all places having separate commissions of the peace, and to all rates of the nature of county rates. Rates in the nature of county rates in boroughs are provided for by the Municipal Corporations Act (5 & 6 Will. IV. c. 76, as amended by subsequent statutes), and in boroughs not within the provisions of the Municipal Corporations Act, the rate is provided for by the 17 & 18 Vict., c. 71. It is to be observed that the police rate, although collected with the county rate, is made a distinct rate. (3 & 4 Vict., c. 88; 19 & 20 Vict. c. 69.)

The county rate is levied on the same description of property as the poors' rate, that is, on lands, houses, tithes impropriate, propriations of tithes, coal-mines, and saleable underwoods: the term "lands" includes improvements of lands, by roads, bridges, docks, canals, and other works and erections not included under the term "houses." Under houses are comprehended all permanent erections for the shelter of man, beast, or property. Mines, other than coal-mines, are exempted, and the exemption extends to limestone and other stone quarries, or to other matter that is obtained by quarrying. The county rate is to be assessed upon parishes "rateably and equally according to a certain pound rate," upon the basis or standard above mentioned, "of the full and fair annual value of the property, messuages, lands, tenements, and hereditaments, rateable to the relief of the poor."

COUPLING, in machinery, is, in a limited sense, the name given to various contrivances for effecting the longitudinal connection of shafts; though, in a more general sense, it may be extended to embrace the arrangements by which the parts of a machine may be connected or disconnected at pleasure, or by which a machine may be disengaged from, or re-engaged with, a revolving wheel or shaft, through which it receives motion from a steam-engine, water-wheel, or other prime mover.

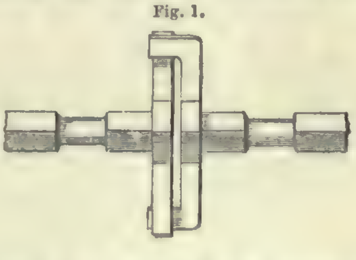
When it is required to communicate motion to a considerable distance from the source of power, as in the distribution of power to the various apartments of a cotton-mill, by gearing such as that represented under WHEELS, it is frequently necessary to construct the long shafts by which the motion is distributed in several pieces, not only owing to the impossibility of making them accurately of the required length, but also because, if they were so made, their expansion and contraction would occasion much inconvenience. It is further desirable, in many cases, to have the option of detaching one portion of a shaft from the moving power without stopping the adjacent portion.

In such cases, each distinct shaft, or portion of shaft, may be perfectly supported by bearings of its own, near each end; or, under certain circumstances, the coupling may be so constructed as to render one of the bearings unnecessary.

The simplest mode of connecting shafts which are supported by bearings near each end, is to make that portion of each shaft which projects beyond the bearings of a square shape, and to unite the adjacent ends by means of a *coupling-box*, which may be described as a square collar fitting the ends of the shafts, and capable of sliding along them in such a way that it will either embrace the ends of *both* shafts, in which case they must turn together like one piece, or that, when it is required to disconnect them, it may be slid fully on to *one* of the shafts, leaving the other entirely free. Holes are provided in both the coupling-box and the shaft, by which a pin may be inserted to hold the coupling-box in whichever position it may be required to retain. Sometimes, instead of the coupling-box being in the form of a sliding box or collar, it is formed in two halves, which may be separated at pleasure, and secured, when put together, by bolts or keys. On account of the greater facility of making them perfectly true, round couplings and coupling-boxes are occasionally used; but as their efficiency in transmitting power depends wholly upon the connecting pins, of which there should be two, passing completely through the shaft at right angles with each other, they are not so strong as square couplings.

Couplings are often effected without coupling-boxes, by the use of what are termed *clutches* or *glands*, in which projections of various forms from arms or discs attached to the ends of the shafts, are employed to lock them together, in some cases only while the machinery is in motion; while, by the removal of one of the engaging members, by sliding it back upon the shaft, the connection may be broken at pleasure. Such contrivances admit of infinite variety, and may be made to disengage themselves whenever the moving power ceases, by fixing one of the engaging members upon a pivot in such a manner that, when the pressure upon it is relaxed, it falls out of the way. This is especially the case with such clutches as act on the principle of the ratchet and click. *Fig.* 1 represents a clutch with projecting arms, which engage with each other by mere contact, and will turn in either direction. As the engaging members of this clutch are not attached to each other, it affords scope for expansion and contraction without occasioning the straining and injury which might be occasioned by a more rigid connection; and it also obviates the difficulty of throwing all the machinery into motion at the same moment, since one shaft may have to turn nearly half round before it has to impel the adjoining one. Sometimes, however, a similar coupling is so constructed that the connection is made by pins passing through the two arms. In some couplings the arms or glands are single, so that the connection may be compared to a common crank, instead of being double, and forming a double crank, as in *fig.* 1; and when it is desired to prevent the machinery from turning the wrong way, the arms may be jointed with a kind of hinge-joint, similar to that of a common two-foot rule, which will cause the bar to be quite stiff to resist a strain in one direction, although, if the motion be reversed, the joint will give way, and the connection will be broken.

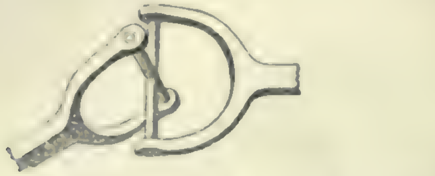
Fig. 1.



When each length of shaft has only one bearing, the coupling must be of such a construction as not merely to compel one shaft to turn with the other, but also to cause the supported end of one shaft to sustain, by a scarfed or mortice and tenon joint, or by some similar contrivance, the unsupported end of the adjoining shaft.

Fig. 2 represents one of various forms of the ingenious contrivance known as Hooke's universal joint, an apparatus by which shafts which do not lie in a straight line with each other, or which are liable to change their relative positions in this respect, may be made to turn each other. While it may be used as a substitute either for an ordinary coupling or for bevil gear, this joint or connection will accomplish what neither of those contrivances can do. As an illustration of the circumstances under which such a coupling may be employed, we may allude to a scheme patented in 1825, by Mr. James, for propelling railway carriages on steep inclinations by communicating the rotatory motion generated in a locomotive engine to all the wheels of every carriage in the train, through the medium of a system of rods thus connected, and consequently capable of receiving and imparting motion, whether the train were in a straight line or on a curve so great as to cause the side of one carriage to form an angle of 30° with that of the adjoining one. The details of this specimen of ingenuity, which is here referred to simply as affording a striking illustration of the powers of the universal joint as a coupling, are given in Hebert's 'Engineer's and Mechanic's Encyclopedia," vol. ii., pp. 465, 466.

Fig. 2.



When power is conveyed to a considerable distance by means of a series of revolving shafts, the motion often becomes irregular and uncertain; but this evil may be in a great measure rectified by placing a fly-wheel to equalise the motion at or near the extremity of the series.

In all contrivances for disengaging and re-engaging machinery while in motion, it is necessary to consider the effect of inertia, which renders it both difficult and hazardous to bring a machine suddenly from a state of rest to one of rapid motion. When the connection is formed by toothed or cogged wheels this difficulty is especially felt, and, consequently, while it is very easy to disconnect such wheels, or, as it is commonly termed, to throw them out of *gear*, either by removing the axis of one of the wheels, or by sliding one wheel along its axis until its teeth are disengaged from the other, they cannot be re-engaged without great risk of breaking the teeth. In this respect, as shown under WHEELS, a connection by means of straps or cords is far preferable. Such a connection always has some degree of elasticity and power of yielding under the effect of sudden strains, and when employed in connection with the fast and loose pulley (a contrivance illustrated under SAW-MILL), it affords perhaps the safest method known of starting and stopping machinery. Sometimes a similar effect is produced by the use of an endless cord or band passing round two pulleys, one of which is on a moveable axle, by the shifting of which the tension of the band may be destroyed. Where neither the axle of the driving pulley, nor that of the driven one, can be made moveable, the same effect may be produced by the use of a third pulley, or drum, so mounted that by pressing it against the band the tension may be increased to any desired amount, or by removing it out of the way, it may be destroyed. The small wheels (*e*, *e*) in the cut of part of Brunel's block machinery, given under SAW-MILL, though merely employed for increasing the tension, and not for taking it off to stop the revolving saw, will illustrate such a contrivance. Bands are sometimes applied to a sliding pulley, which may be locked to the machinery at pleasure by engaging it with revolving glands, or with a bayonet coupling; but in such a case the shock of starting is not avoided, though the elasticity of the band, and its power of slipping on the pulley under the effect of sudden resistance, render it less hazardous than with cog-wheels.

Clutches or bayonet connections are sometimes employed to start a train of wheelwork in which the teeth themselves are never actually thrown out of gear. The disadvantages of such a mode of coupling may be in a great measure avoided by the use of a *friction clutch*, in which the driving arms or projections are attached to an elastic open hoop or band of metal, sprung on to a smooth wheel or drum, and fitted with tightening screws, by which it may be pressed to any degree of tightness; so that while it will slip round until the inertia of the machinery is overcome in starting, or under the effect of accidental resistance, its friction will be sufficient, under ordinary circumstances, to cause it and the drum to turn together, as if they were one piece.

In another contrivance of the same character the connection is effected by pushing a solid conical wheel or drum, mounted upon one shaft, into a hollow cone attached to an adjoining shaft, in doing which the friction, and consequent power of transmitting motion, increases in proportion to the advance of the solid into the hollow cone. Friction wheels, with their peripheries formed of the end of the grain of wood, which may be compared to a collection of indefinitely small teeth, pressed together by levers, or friction wheels or discs placed side by side so as to be either a little separated or pressed together at pleasure, are also occasionally used. A coupling which starts the machinery gradually by friction may be connected with a fixed clutch or bayonet coupling in such a way that, when once started, the connection of the machinery shall be rigid, and no longer dependent upon mere friction.

Very full details upon the subject of this article are given in the excellent 'Practical Essays on Mill-Work and other Machinery,' by Robertson Buchanan, with additions by Tredgold and George Rennie, 8vo, Lond., 1841, pp. 262-306, where allusion is made to couplings which disengage themselves under the influence of any undue strain upon the machinery, and a plan is proposed for diminishing the risk of engaging cogged wheels, by introducing spring spokes in the larger wheel of the pair, the teeth of which are more likely to break than those of the pinion. The subject is also treated at some length in Barlow's 'Treatise on Manufactures and Machinery,' in the 'Encyclopædia Metropolitana,' sect. 46-51.

COURANTE, or CORANTO, a quick dance in triple time. In Handel's, Mattheson's, and other lessons for the harpsichord, composed towards the end of the 17th and beginning of the 18th centuries, a *Courante* is generally introduced as one of the movements.

COURIER, from the French *courir*, to run; a messenger sent in haste, or express; a bearer of despatches. The advantage of receiving the earliest intelligence, and of conveying orders with celerity, must have given rise to the employment of couriers at a very early period. Herodotus (viii. 98) gives a particular description of the speed of the Persian royal messengers who proceeded by relays. He says this mode of conveying intelligence was called by the Persians *ἀγγαρήϊον* (Angareïon); and the couriers themselves *ἄγγαροι* (angaroi). Another description of couriers among the Greeks were called *ἡμεροδρόμοι*, who appear to have been armed with a light spear or dart, &c. (Suidas *in voce.*) Herodotus (vi. 105) says that a little before the battle of Marathon, Pheidippides (an *ἡμεροδρόμος*, a runner by profession) being sent by the Athenian generals, arrived at Sparta on the second day after leaving Athens, a distance not less than 140 or 150 miles. (See also Suidas, *v.* Ἱππίας.) The mode of employing couriers by Cyrus, as described by Xenophon ('Cyropædia,' viii., 6), appears to be nothing more than the system already referred to as described by Herodotus. He ascertained the journey which a horse could fairly perform within a day, and placed stables at regular distances, so that messengers could receive or deliver letters from hand to hand.—Gibbon, in his 'Decline and Fall of the Roman Empire' (chap. ii.), speaks of the swiftness and regularity of the Roman posts. The Romans called such messengers *cursores*: they were sometimes sent on foot and sometimes on horseback. The earliest couriers of the European nations were probably what have since been called running-footmen. In manuscripts of the 13th century such messengers are occasionally styled *trottarii* or trotters. The running-footmen or couriers, who accompanied John Duke of Marlborough in his wars, are several times represented in the tapestries at Blenheim-house. The word has also been used in modern times for a travelling attendant on persons or families journeying in a foreign country.

COURSE OF EXCHANGE. [EXCHANGE.]

COURT BARON. [MANOR.]

COURT-MARTIAL, a tribunal occasionally instituted for the purpose of trying military and naval men for the commission of offences affecting discipline in either of those branches of the public service.

Courts for the trial of rebels by martial law appear to have early existed in this country; and in the time of Henry VIII., the Marshal of England held one regularly for the trial of causes connected with military discipline. In the reigns of Elizabeth and her successor, those courts of war, as they were called, were superintended not by the marshal, but by a president chosen for the purpose. This president was probably a general or field-officer, but captains of companies were allowed to sit as members. The colonel of each regiment was charged with the duty of preparing the evidence relating to offences which fell under his cognisance, and of bringing it before the court.

But courts-martial in their present form were instituted in the reign of James II. in the year 1686, when ordinances of war were issued for regulating the discipline of the army. Since the revolution of 1688, their existence and jurisdiction depend on the will of Parliament, expressed year by year in statutes known as the Mutiny Act, and the Marine Mutiny Act, which are expressly limited to the duration of one year. Naval courts-martial differ in this from courts-martial in the army or the marines, that the former derive their constitution and authority from a permanent statute, the 22 Geo. II., c. 33. The East India Company's European troops in India continued to be subject to the Mutiny Act and Articles of War, in force with regard to the troops of the United Kingdom, until the year 1754, when an Act was passed, and Articles of War, very similar to those in force for the royal army were promulgated expressly for that division of the Company's troops. A new code was afterwards framed in the year 1823, and alterations have been made in successive years up to the latest Act, passed in July, 1849, and the Articles of War, issued the same year. The Company's native troops continued to serve, subject to the discipline and rules of the British Mutiny Act and Articles of War, till separate codes were framed for the three presidencies in the end of the last century. These separate codes for the native troops were revised and consolidated in the year 1845, and again altered and framed anew, as a single code for all the native troops of the Company in 1847. By the Act for 'the better Government of India,' the 21 & 22 Vict., c. 106, transferring the powers and jurisdiction of the East India Company to the Crown, the military and naval forces of the East India Company are to be deemed to be the Indian military and naval forces of her Majesty, and are continued on the same footing, and subject to the same regulations, statutes, and articles of war in all respects as existed at the time of the passing of the Act.

Courts-martial may be of three kinds; general courts-martial, district or garrison courts-martial, and regimental courts-martial.

General courts-martial are assembled under the authority of the queen, or of an officer, having the chief command within any part of her Majesty's dominions, to whom such authority may be delegated by commission or warrant under the sign manual. Regimental courts-martial are held by the appointment of the commanding officer of the regiment. What are called detachment courts-martial, may be either general or regimental, and their appellation is derived from the nature of the command with which the officer convening the court is invested.

The chief crimes of which a general court-martial takes cognisance are mutiny, traitorous correspondence with the enemy, abandonment of a fortress, post, or guard committed to the charge of an officer or soldier, disobedience of orders, and desertion; these crimes, if proved to their greatest extent, are punishable with death; and the penalty extends to any military man, being present, who does not use his best endeavours to prevent them. The crime of desertion includes the fact of enlisting in any regiment without having had a regular discharge from that in which the offender may have last served. The practice of sending challenges between commissioned officers, is punished with cashiering; between non-commissioned officers and privates, with corporal punishment; and, in all cases, seconds and accessories are held to be equally guilty with the principals. Self-mutilation, theft, embezzlement of money or of stores, making false returns of stores, and neglect of ordinary duty, in non-commissioned officers and privates, are punishable with penal servitude, imprisonment with or without hard labour, and in addition thereto with the forfeiture of all additional pay or good conduct pay or claim to pension upon discharge, corporal punishment not exceeding fifty lashes, or discharge from the service with ignominy; and men of the former class may, in addition to other punishments, be suspended, or degraded to the ranks. There are many offences which might tend to the subversion of discipline, but which are hardly capable of being precisely defined, such as immoralities, and behaving in a manner unbecoming an officer and a gentleman; of these the courts-martial take cognisance, and on conviction the offender may be dismissed from the service. At home, military men are not, in general, amenable to courts-martial for civil offences; but abroad, where there may be no civil courts, the case is different.

The provisions of the Mutiny Act affect not only the cavalry and infantry of the regular army, but extend to the officers and privates in the corps of artillery, engineers, military surveyors and draughtsmen, or in the field or military train, or medical staff corps, or hospital corps; to all troops serving in India, or serving in the colonies; to the militia and yeomanry, during the time that they are assembled and being trained, if expressly so provided by the Act embodying them. Discipline in the marines is regulated by the Marine Mutiny Act. All are subject, without distinction, to trial and punishment by courts-martial.

The rules of the service require that the president of every general court-martial should be a field-officer, if one of that rank can be obtained; but he must not be inferior in rank to a captain, save in the case of a detachment general court-martial holden out of the crown's dominions, where a captain cannot be obtained. And it should be observed, that none of the members are to be subalterns when a field-officer is to be tried. The president of every court-martial is appointed by the authority convening the court, and it is required that such president shall in no case be the person whose duty it is afterwards to confirm the proceedings, or has been, previously, to investigate the charges on which the prisoner was to be arraigned. A judge-advocate is appointed to conduct the prosecution in the name of the sovereign, and act as the recorder of the court.

No general courts-martial held in Great Britain or Ireland, the Ionian Islands, or British India, are to consist of less than thirteen commissioned officers; in St. Helena, British settlements on the western coast of Africa, Honduras, New Zealand, the Australian colonies, British settlements on the coast of China, Prince of Wales' Island, Singapore and Malacca, of less than five; in Jamaica, the Windward and Leeward Islands, British Guiana, Newfoundland, Bermuda, the Bahamas, the Cape of Good Hope or other settlements in southern Africa, or any place out of the British dominions excepting the places already mentioned, of less than seven commissioned officers. Commonly, however, a greater number are appointed, in order to guard against accidents arising from any of the members being found disqualified, or falling sick. An uneven number is purposely appointed, in order that there may be always a casting vote; and the concurrence of two-thirds of the members composing the court is requisite in every capital sentence. No officer serving in the militia can sit in any court-martial upon the trial of an officer or soldier in the regular army; and no officer in the regulars is allowed to sit in a court-martial on the trial of an officer or private serving in the militia. The members of the court take rank according to the date of their commissions; they are always sworn to do their duty; and the evidence on the trial is taken upon oath.

In the accusation the crime or offence must be clearly expressed, and the acts of guilt directly charged against the accused; the time and place must be set forth with all possible accuracy; and, at a general court-martial, a copy of the charge must be furnished by the judge-advocate to the accused, that he may have full opportunity of preparing his defence. The accused has the power of challenging any of the members, but the reason of the challenge must be given, and this must be well-founded, otherwise it would not be admitted; for the ends of justice might be often defeated from the impossibility of getting members to replace those who were challenged.

The court must discuss every charge brought against the accused, throwing out only such as are irrelevant; and judgment must be given either upon each article separately, or the decision of the court upon all may be included in one verdict. The evidence is taken down in writing, which affords to every member of the court the opportunity of comparing the proceedings with his own private notes, and of thus making himself completely master of the whole case before he is required to give his opinion. At the last stage of the trial, the decisions of the several members are taken in succession, beginning with the junior officer on the list; a regulation obviously adopted in order to secure the unbiassed opinions of those who might otherwise be influenced by deference to the members who are superior to them in age or rank.

District or garrison courts martial must consist of not less than seven commissioned officers, except in Bermuda, the Bahamas, Cape of Good Hope, or other settlements in Southern Africa, St. Helena, Jamaica, Honduras, Newfoundland, New Zealand, the Australian Colonies, the Windward and Leeward Islands, British Guiana, Hong Kong, and the settlements on the Coast of China, where it may consist of not less than five; and in the settlements on the western coast of Africa, where it may consist of not less than three commissioned officers. The president must be a field officer if such officer can be had, and if not, then an officer not under the rank of captain; and the power of the court is the same as that of a general court-martial, save only that it cannot try a commissioned officer, or pass any sentence of death or penal servitude.

Regimental or detachment courts-martial are appointed by the commanding officer, for the purpose of inquiring into criminal matters of the inferior degrees; and they are empowered to inflict corporal punishments or imprisonment, and forfeiture of pay for a limited time. The Mutiny Act and Articles of War require that not less than five officers should constitute a court of this nature, or three when five cannot be obtained. The president must not in any case be under the rank of a captain, save in the case of a court holden on the line of march, or on board a transport-ship, convict-ship, merchant-vessel, or troop-ship, not in commission, or on any foreign station where a captain cannot be had. The practice is to appoint a captain as president, and four or two subalterns as the case may be; the court has no judge-advocate to direct it; and the members therefore must act on their own responsibility. The proceedings are to be taken down in writing, and the sentence cannot be put in execution till it has been confirmed by the commanding officer, or by the governor of the garrison.

An inferior officer, or private soldier, who thinks himself wronged by a commissioned officer, may, on application to the commanding officer of the regiment, have his cause brought before a regimental court-martial, although no commissioned officer is amenable to that tribunal, and, if the complaint is judged to be well founded, he may on that authority require a general court-martial to be held.

An appeal by the party who conceives that he has suffered injustice, lies from a regimental to a general court-martial. But upon a matter which clearly lies within the jurisdiction of the courts military, there is no appeal to the courts of law or equity. Yet as courts-martial are bound to act within their proper jurisdiction and in accordance with the ordinary rules of evidence, irregularities, of a character which amount to a denial of justice, will afford a sufficient ground for the Supreme Courts of Law to interfere, either by a prohibition to stay the proceedings, or to set aside the sentence, and discharge the prisoner, or to grant a writ of *habeas corpus* to bring up the prisoner with a view to staying execution of the sentence, and affording time for further inquiry.

After the sentence of the court-martial has been ascertained, it is transmitted to the sovereign, who may either confirm it, or, if sufficient reason should exist, may, on the ground that the process is not complete till the sentence has received the royal sanction, return it to the court for revision; or without having recourse to any such step, it is within the royal prerogative to remit the punishment awarded.

The chief distinction between the trial by court-martial and by jury is, that in the latter the verdict must be unanimous, while in the former the concurrence of a majority only determines the verdict; but if it should happen in courts-martial composed through necessity of an even number, that the court is equally divided, this is received as a verdict of acquittal. Judgment of death, however, cannot be given but with the concurrence of two-thirds of the court. No officer or private soldier, or other person subject to the laws of war, who has been acquitted by the civil magistrate, or by the verdict of a jury, is liable to be tried again by a court-martial on the same charge; the crown, however, has still the power, notwithstanding such acquittal, to dismiss the officer from the service, and thereby save the profession from the society of a guilty man, who has escaped through a failure of justice only; but such prerogative of the crown is properly limited to the power of cashiering.

Naval courts-martial had no legal existence before the year 1661, and even custom till then had only sanctioned a reference of causes of complaint in the fleet to the decision of two or three senior officers in accordance with "the usages of war;" but by the 13 Car. II. c. 9, tribunals of this nature were established, and their jurisdiction ascertained, the crimes triable before them being determined, and the punishments which they might inflict. That statute was repealed by the 22 Geo. II. c. 33, and the law relating to them is now to be found in this Act, and in the 19 Geo. III. c. 17; the 10 & 11 Vict. c. 59; and the 10 & 11 Vict. c. 62; the Articles of War; and the queen's regulations together with the instructions issued to the fleet by the Board of Admiralty in 1844. The person empowered to assemble a court-martial in the navy is the officer in chief command of the fleet or squadron, who has received authority for that purpose by warrant from the Board of Admiralty; or the senior officer, commanding a detachment of the fleet or squadron on separate service, who has received such authority under the hand of the officer in chief command that sent him in command on separate service. A court-martial must consist of not more than thirteen, and not less than five officers, and these officers must be the senior flag officers and captains, *then and there present;* but in case there should be a scarcity of flag officers and captains on the station, the court may consist of three post-captains and the two senior commanders. A court which includes more than two commanders is not legally constituted. An officer who is not on full pay and in commission in his proper rank, may not serve as a member of the court; nor may an officer, whose rank entitling him to be a member, has only been conferred on him by the officer commanding in chief, and not yet been notified to him by the Admiralty. Every officer, in order to be capable of serving, is required to be *then and there present*, which is held to mean that the captain's or commander's ship must be on the station, and that an admiral, if he come from another station for the purpose of serving, must hoist his flag on a ship in commission at the station in question. If a sufficient number of ships should meet at any foreign station, the statute authorises the officer who shall be senior in command to assemble a court martial, but it is held that he cannot do so without the special warrant of the Admiralty sent to him for that purpose. The court must be held afloat; it cannot assemble on shore without a special Act of Parliament to give it the right. There is no power of challenge, as of right, either to the Judge Advocate or to the prisoner; but as a matter of courtesy, challenges are allowed in practice for good and sufficient reason given. When the court has been completely constituted, the members are sworn to do their duty, and so also is the Judge Advocate; the evidence is taken upon oath; and the court sits from day to day, except Sundays, until the sentence is given. Were it to adjourn even over one day only, the proceedings would thereby be rendered illegal. The jurisdiction of the court extends not only to the usual offences known to the criminal law of this country, but to offences against the discipline and duty observed by the service. Charges against a prisoner cannot be proceeded with unless they have been made in writing to the Lords of the Admiralty, or to the officer commanding in chief, within three years from the time of committing the offence, or within one year after the return of the fleet, squadron, or ship, in which the offender is serving, or of the offender himself to Great Britain or Ireland. And the prisoner is entitled to have a copy of the charges against him twenty-four hours before the trial, unless there be extraordinary circumstances to excuse it, as in the case of sudden mutiny; but he is not entitled to any copy of the evidence by which the charges are to be sustained.

COURT OF RECORD. [COURTS.]

COURT ROLLS. [COPYHOLD.]

COURTESY OF ENGLAND is the title of a husband to enjoy for life, after his wife's decease, the real property of the wife. It is said to be called the "courtesy of England" as being a law peculiar to this country. In the law of Scotland, however, it is known by a similar title, as the courtesy or "jus curialitatis." It is spoken of in a Rescript of Constantine, Cod. vi., 59, 1; and in the laws of the Alemanni (Lindenbrog, 'Codex Legum Antiquarum,' 1613, p. 387; 'Lex Aleman.,' c. 92); though by the law of the Alemanni the husband took the inheritance under circumstances similar to those that establish the title to a life estate only in the English law. This title of the husband's tenancy of the estates of his wife depends upon a valid marriage, the seisin of the wife during marriage of the same estate respecting which the courtesy is claimed, issue born alive during the wife's life capable of inheriting, and the death of the wife. Lands held by the wife descendible only to her sons would not, in case of the birth of a daughter, be subject to this title of the husband; nor would a child brought into the world by the cæsarean operation, after the mother's death, establish it. It differs from the similar rights of the wife to dower in several respects, the wife taking only part of the husband's estate, and being entitled to her tenancy though no issue is born; whereas the husband takes the whole estate, the caput baroniæ, and such indivisible rights out of which dower is not or cannot be assigned. By the custom of Gavelkind, a man may be tenant by the courtesy without having had issue by his wife.

COURTESY OF SCOTLAND, otherwise called in the law of that kingdom "jus curialitatis," or right of courtship, is substantially the same with the courtesy of England. As in the latter kingdom, five things are necessary to it; namely, marriage, that the wife is an heiress and infeft, issue, and the death of the wife.

According to the ancient law, the courtesy extended only to such lands as the woman brought in tocher; but afterwards it became extended to all the lands to which she had right by inheritance. It was always the law that the wife must be seised. The fourth requisite is, inheritable issue born alive of the marriage; that is to say, the child born must be the heir of the mother's estate, and it must have been heard to cry: for though it be otherwise in England, crying is in Scotland the only legal evidence of life. In the last place, by such issue the husband has during the life of the wife only *jus mariti*, as Skene says ('De verb. signif. voce Curialitas'); after her decease he has *jus curialitatis;* or, as Blackstone speaks, with reference to the law of England, the husband by the birth of the child becomes tenant by the courtesy *initiate*, but his estate is not *consummated* till the wife's death, which is the fifth and last requisite to give the complete right of courtesy, the husband needing no seisin or other solemnity to perfect his title.

COURTS. The courts of common law in this country, like most other branches of our constitution, have grown up gradually with the progress of the nation, and may be traced back, partly to the institutions of our Anglo-Saxon forefathers, and partly to the more artificial systems introduced under the government of the Normans. From the earliest times of which we have any account, we find the tribunals of the Germanic nations consisting of a presiding officer, called Graf Reeve or Earl, Comes or Count; together with certain assessors, whose denominations (and probably their functions also) were different among different tribes and at different periods. Of this nature were the earliest tribunals with which we are acquainted in this country. The most important of these was that whose jurisdiction extended over a shire or county, in which the presiding officer was at first the alderman, earl, or count, and subsequently his deputy the vice-count or sheriff (shire reeve). This tribunal exercised ecclesiastical as well as civil jurisdiction, and the bishop sat as an associate to the earl or sheriff.

The judicial functions of this court were divided into four distinct branches. The first included all ecclesiastical matters; and in these the bishop was judge, and the sheriff the assistant, who, if necessary, enforced the sentence of the court by imprisonment. The second branch (in which the sheriff was judge) included all temporal offences, such as felony, assaults, nuisances, and the like. The third head included all actions of a purely civil nature: here the sheriff was the presiding officer, and executed the judgment; but the judges were the freeholders who did suit to the court. And fourthly, the sheriff's court held an inquest yearly of frank pledge. The first branch of the jurisdiction of this tribunal was transferred to the Church by the Conqueror, and the bishop soon ceased to sit with the civil magistrate. The criminal jurisdiction of the sheriff has long been obsolete; his civil jurisdiction has been transferred to the new County Courts [COUNTY COURTS]; and the view of frank pledge now exists only as a form.

In order to exercise his criminal jurisdiction, the sheriff was required twice in every year to make a tour or circuit of his county. The power of determining felonies was taken away by Magna Charta, but the remains of this tribunal are still known as the sheriff's tourn, and in it cognisance may be taken of false weights, nuisance, and other misdemeanors. The view of frank pledge ought to be taken at this tourn.

The land over which the jurisdiction of the sheriff extended is said to have been distinguished as reeve land. The thanes or nobles had, in the lands granted to them, a similar jurisdiction of their own, as well civil as criminal. (1, Reeve's 'Hist. of English Law,' 7.) The limits between the jurisdiction of the sheriff and that of the lord were strictly preserved. But when the lord had no court, or refused to do justice, or when the parties were not both subject to his jurisdiction, the suit was referred to the tribunal of the Reeve; and a suit commenced before the lord might be removed by the defendant before the higher tribunal.

The civil tribunal of the lord was similar to the county court in its constitution and its powers, except that the presiding officer was not a public functionary (as the reeve was), but the bailiff of the lord. This tribunal still exists under the style of the court-baron, and is incident to every manor in the kindom. The judges are the freeholders who owe suit and service to the lord of the manor, and if there are not at least two such freeholders in the manor the court is lost. This was formerly the proper court in which to commence real actions to try the title to lands within the manor. The lord's tribunal in criminal cases, in which he had the same powers that the sheriff exercised in his tourn, was called the Leet.

The same powers which were exercised over a particular manor by the court baron and court leet were also exercised over particular hundreds by the hundred court and the leet of the hundred. But the number of these courts was much diminished by stat. 14 Edward III., by which all hundreds, except such as were of estate in fee, were rejoined (as to the bailiwick of the same) to the counties at large.

Besides these courts of inferior jurisdiction, there was also a supreme tribunal, in which the king presided. In the Saxon age, and for some time after, the legislative, the administrative, and the judicial functions of the government had not been separated; and the Wittena-gemote, or meeting of the wise, was consulted by the monarch in all these departments indiscriminately. The Anglo-Saxon king had the same jurisdiction over his thanes that they had over their own vassals. He punished all enormous crimes committed against the king's peace. His court was likewise open to all those to whom justice had been refused in the inferior tribunals; and he had the power of punishing the judges if they pronounced an iniquitous sentence. It also seems probable that the king's court was a court of appeal, in which the judgments of all other tribunals, if erroneous, might be reversed.

The Norman Conquest does not seem to have produced any immediate change in the constitution of this national assembly, which thenceforth became more known as the Great Council. Its members exercised the same varied functions as under the Saxons; but when they sat in their judicial capacity, they had the assistance of the great officers of state and certain persons learned in the law, styled Justiciars, or Justices. William the Conqueror also created an officer to preside over judicial business, under the title of Chief Justiciar. The functions of this tribunal thus became gradually separated from the general business of the grand council; and from being held in the hall of the king's palace it was distinguished by the style of Aula Regis. A great distinction was drawn between this and all the courts of Saxon origin, from the mode of authenticating its proceedings. There were at this time no written memorials of legal proceedings, and indeed of few other public acts; and when it was necessary to establish any judgment or statute which had been made by the king assisted by his council, it was usual to call the testimony of some of the nobles who were present to bear *record* of the fact. In progress of time, all such proceedings were written down at the time on parchment, the nobles present signing their names as witnesses, and so bearing record of the truth of what was there alleged. The writing itself was called a record; and it was held to be evidence so conclusive that, when produced, nothing was allowed to be alleged in derogation of it. The entry of proceedings on record was adopted in the judicial, as well as in the other departments of the great council, and hence the Aula Regis became distinguished as *a court of record*. The power and importance of the Aula Regis rapidly increased. It not only maintained the former powers of the council in punishing offences against the public, in controlling the proceedings of inferior courts, and in deciding on questions relating to the revenue of the king, but it engrossed also a great portion of the "common pleas," or causes between party and party. And though we may suppose that it was only the more important causes that were taken into the Aula Regis, yet as early as the reign of Edward I., when the jurisdiction of the county courts was confined to 40*s*., all actions above that amount were brought into the king's courts.

The Aula Regis seems at a very early period to have been distinguished as exercising three several capacities, according to the different natures of the causes that were brought before it, which are treated of in our earlier legal writers as pleas of the king, common pleas, and pleas of the exchequer. The bond of connection between these several jurisdictions was the chief justiciar, who presided over all of them. But in the reign of Edward III. this office was abolished, and thus were finally destroyed the unity of the Aula Regis and its connection with the grand council, which became henceforth essentially a legislative body; and though it still retains traces of its original functions in its title of the *High Court* of Parliament, yet it has ever since ceased to exercise any judicial powers, except in cases of impeachment, or as a court of ultimate appeal. On the dissolution of the Aula Regis, the three courts of the King's Bench, the Common Pleas, and the Exchequer, had each of them a perfectly distinct and separate existence. The Court of King's Bench had the control of all the inferior tribunals and the cognisance of all trespasses against the king's peace; the Court of Exchequer had cognisance of all cases relating to the revenue; and the Court of Common Pleas was the only tribunal for causes of a purely civil nature between private persons. The courts of King's Bench and Exchequer still retain each of them its peculiar jurisdiction; and the Common Pleas is still the only court in Westminster in which a real action can be tried; but the great mass of causes between party and party may now be brought indiscriminately in any of the three courts. The mode in which the King's Bench and the Exchequer originally contrived by fictitious proceedings to appropriate to themselves a share in the peculiar jurisdiction of the Common Pleas will be found in the accounts given of those courts.

The Saxon kings had been in the habit of making progresses through their dominions for the purpose of administering justice. This practice was not continued by William the Conqueror; but he annually summoned his great council to sit at the three feasts of Easter, Whitsuntide, and Christmas, in three different parts of the kingdom: Winchester, Westminster, and Gloucester. But when the great mass of the legal business of the country was brought into the king's courts at Westminster it became necessary to take some more efficient measures for the trial of causes in the country.

The first expedient adopted was to appoint itinerant judges, Justices in Eyre, who travelled through the kingdom, holding plea of all causes civil or criminal, and in most respects discharging the office of the superior courts. These itinera or eyres usually took place after an interval of seven years. From them we have our modern assizes; the immediate origin of which was a statute of Edward I., which in order to prevent the expense of bringing up juries to the courts at Westminster, provided that certain judges of those courts should be appointed to make circuits twice a year for the trial of issues, upon which judgment was to be given in the court above. These justices are appointed by commissions of Oyer and Terminer and of gaol delivery, which authorise them to try criminals. They have also a commission of the peace, and a commission of assize, under which they used to try a peculiar species of action called assizes. These actions have long been obsolete; but the name of assizes is still given to the sittings of the justices on circuit under their several commissions.

Under the Norman kings the fines, amerciaments, and forfeitures in the courts constituted a considerable portion of the revenue, and the administration of justice was held to be an important branch of the royal prerogative. But, like other branches of the prerogative, we sometimes find it in the hands of a subject, either by grant from the crown, or by prescription, which, in the eye of the law, supposes a grant, though such supposition is often at variance with probability; within the counties palatine and other royal franchises, the earls or lords had regal jurisdiction, saving the supreme dominion of the crown. They had the same right as the king to pardon offences; they appointed judges of eyre, assize, and gaol delivery, and justices of the peace; all legal proceedings were made in their name, and offences were said to be committed against their peace, as in other places against the peace of the king. These royal prerogatives were, for the most part, reannexed to the crown by stat. 27 Henry VIII.; but the form of the judicial establishment still remained. The County Palatine of Pembroke was abolished by the same statute, and the County Palatine of Hallamshire shared the same fate in the reign of Elizabeth. The Counties Palatine of Chester and Lancaster are still in existence, but have long ceased to be in the hands of subjects. The palatinate jurisdiction of Durham continued to our own day to be possessed by the bishop, but this also has been vested in the crown. By another statute the secular jurisdiction of the bishop of Ely has been abolished.

But besides these palatinate jurisdictions, created to increase the power and gratify the pride of the nobles on whom they were conferred, the crown has also from time to time erected courts, with a jurisdiction limited in point of territory, and always under the control of the superior courts. In the Saxon times the boroughs had courts similar to those of the hundreds; and as commerce increased, it was found of the utmost importance to them to be relieved from the jurisdiction of the feudal lord, and at the same time to have some court of justice to apply to, less distant, dilatory, and expensive, than the courts at Westminster. Accordingly there has, at some time or other, been granted to almost every borough of any importance, the power of exercising civil and criminal jurisdiction within certain prescribed limits. These courts were in all cases courts of record, but in other respects were not modelled on any uniform system. There was the greatest possible variety in their constitution and the extent of their powers. But the mode of proceeding in all of them was founded on the common law and the practice of the superior courts, and a writ of error lay into the King's Bench, except from the courts of London and the Cinque Ports. By far the greater number of these courts have fallen into disuse, but many of them still exist in great efficiency, particularly in London, Bristol, Manchester, Liverpool, and other cities and towns.

The courts at Westminster, when a cause commenced there has been carried through all its preliminary stages, may send it by writ of trial, to be tried before a judge of one of these borough courts, the judgment, after trial, being given in the superior court.

The administration of justice, which, under the Saxons, was essentially local, rising from the smaller jurisdiction gradually to the higher, became, under the Norman dynasty, centered in one point, the monarch being the fountain of justice. This system of centralisation, connected as it was with the principles of feudalism, which so long prevailed in this island with peculiar force, was elaborated, in the course of centuries, to a high state of perfection; it absorbed the remains of the ancient local jurisdictions, and stunted all attempts at the establishment of new. But as the artificial systems and feudal associations, for which we are indebted to the Normans, gradually wore away, the public mind became prepared to revert to the simpler and more poular institutions which existed ages ago among our forefathers, and which seem to be peculiarly adapted to the character of the Germanic nations. This led to the establishment, in all populous places, of courts of requests and courts of conscience, which to some extent supplied the place of the ancient local courts, and finally to the creation in 1846 of the new county courts [County Courts], by which the administration of civil justice has once more been brought to every man's door.

The great mass of the litigation of the kingdom is carried on by means of the superior courts of Westminster; which term includes the court of chancery. The origin of the jurisdiction exercised in that court is explained elsewhere. [Chancellor; Chancery.] A similar observation applies to what are usually called the superior courts of common law [Common Pleas; Exchequer; Queen's Bench]; although that term strictly includes the palatine courts.

In each of the supreme courts of common law there is a chief and several puisne judges. In the exchequer these are styled the chief baron and barons, no doubt bearing in their title traces of the time when their office was filled by the lords of parliament. Another remnant of the original constitution of the courts appears in the appellation of "my lord," which is always given to the judges in their official character.

During the terms, which are four periods in the year of about three weeks each, the three courts sit at Westminster for the determination of all questions of law; and twice a year fourteen of the judges make their circuits through England and Wales, to try, with the assistance of juries, all disputed questions of fact that arise in the country. Actions brought in Middlesex or London are tried in the same manner at the sittings which are held on certain days in and immediately after every term.

From each of the three courts there lies an appeal to the Court of Exchequer Chamber, whence a further appeal lies to the House of Lords.

(Reeve, *History of the English Law*; Maddox, *History of the Exchequer*; Palgrave, *Progress of the English Commonwealth*; Allen, *Inquiry into the Prerogative*.)

COURTS, ECCLESIASTICAL. [Ecclesiastical Courts.]

COVE, is a small inlet on a rocky coast. When the indentation is wide and deep enough to admit vessels of fifty tons burden and upwards, it is called a harbour; but when it is too narrow for that purpose, and can only be entered by small craft, it is called a cove.

COVENANT is a written agreement, by deed under seal, between two or more persons, whereby some act is agreed to be done; or, upon the happening of some event, some charge or liability is agreed to be borne by some party thereto. The person entering into the agreement and subjecting himself to the penalty of its breach, is called the covenantor, and the person with whom it is made, the covenantee. The portion of the agreement which expresses the character of the liability of the covenantor is called the lien.

Covenants take many varieties of forms, and are variously stated. They usually arise from the express words of the parties, but any words denoting the intention are sufficient: as, "I agree," "I am content." They are sometimes inferred, by law, from the relation of the parties or from the nature of their contract. Thus a demise for a term of years, will sustain, upon an implied covenant, an action for quiet enjoyment.

The lien of covenants usually contains introductory words, declaring the extent of the covenant. If there are several covenantors, it usually declares the covenant to be several, or joint, or joint and several. In case the covenant is several, each of the covenantors covenants for himself alone, and may be sued alone; if joint, each of the covenantors covenants for himself as well as for each other, and all must be sued together; if joint and several, each party covenants for himself, and as a surety for those with him, and an action, in this case, may be brought against one of the covenantors only, or, against all. The courts, however, even in these cases, regard the interests of the parties; and if the interest, or cause of action, is joint, the action must be brought against all the covenantors, though the terms of their covenant may be joint and several; and if the interest, or cause of action, is several, though the covenant is joint, the parties must be severally sued. The reason is, that difficulty would arise if judgment in distinct actions should be asked for one and the same cause against several persons, or against persons whom there is no cause of action to affect. The mere terms of a covenant are not therefore a sufficient guide to determine the propriety of joining parties in an action upon it.

Covenants are divided into real and personal, though, as now used, they are as to remedy, chiefly personal.

The former affect realty, and may bind the real estate of the covenantor in the hands of the heir and of his assigns. Personal covenants bind only the covenantor, or his executors and administrators, that is, his personal estate in their hands. The objects of real covenants are generally to afford some specific advantage or protection to those into whose hands the realty to which they relate shall pass; or, to secure the performance of some specific duty by those who may possess the realty to which they relate.

In the construction of all covenants the intention of the parties is regarded. The general rules usually laid down for this purpose depend upon the presumed intention of the parties; and for this reason, a statute declaring the effect of certain covenants, and enabling them to be stated in a few words, has often been desired, in order to shorten the length of conveyance and to avoid litigation. By such a measure the express intention of the parties would always appear in deeds, by their adoption of the abbreviated language of the law, or by their restraining its general effect. Indeed, in the statutes relating to the registry of deeds in Yorkshire, it is declared that the words "grant, bargain, and sell," are to operate as covenants for title, for farther assurance, and for quiet enjoyment, while on the other hand the stat. 8 & 9 Vict. c. 106, enacts, that in deeds executed after Oct. 1, 1845, the word "give" or the word "grant" shall *not* imply any covenant in law in respect of any tenements or hereditaments except so far as the word "give" or the word "grant" may, by force of any act of parliament, imply a covenant.

The intention of the parties, however, is not always sufficient, in the case of real covenants, to secure their object. It is frequently desirable, when the possession of land is parted with, that the purchaser and his assignees should always be able to resort to the vendor or to his heirs for protection, or that the purchaser and his assignees should perform certain duties, and that the covenants for these purposes should always be connected with the party enjoying the land, or, in other words, that such covenants shall "run with the land." In order that this shall occur, the mere intention of the parties, however definitely expressed, is insufficient; there must also be privity of estate. When land mortgaged in fee was demised by the mortgagor, a covenant entered into with him was merely personal; for though in equity the owner of the estate, at law the mortgagor is a mere stranger to it: there was no privity of estate between the lessor and lessee. (Webb *v.* Russell, 3 Term Rep., 402, 678; 1 Hen. Blackstone, 562.) The assignee also must come in of the same estate as his assignor, or the covenant will also be merely personal. Thus, a covenant to pay a fee farm rent, in a deed enabling the purchaser to appoint his estate to uses, became a mere personal covenant by the exercise of the power to appoint, for the appointment did not convey the same estate that the purchaser had acquired. (Roach *v.* Wadham, 6 East. 289.) [Uses.] The Real Property Commissioners have stated three rules respecting covenants running with the land.

1. A covenant to run with the land so as to bind the assignee, or to give to him the benefit of it without his being named, must relate directly to the land, or to a thing parcel of the demise; such is a covenant to pay rent, to keep buildings in repair, or to observe particular modes of cultivation. 2. When it respects a thing not in existence, but which, when it comes into existence, will be annexed to the land, the covenant will bind the assigns by naming them, but will not bind them unless named; such is a covenant to erect buildings, or to plant trees. 3. When it respects a thing not annexed, nor to be annexed, to the land, or a thing merely collateral, or in its nature merely personal, the covenant will not run, that is, it will not bind the assignee, nor pass to him, even though named; such as a covenant to haul coals to the lessor's house, to grind corn at his mill, or to buy or sell stock in a certain manner. These rules, however, though originally laid down with reference to leases, have been treated as applying to cases not involving the relation of landlord and tenant. They involve many subtle distinctions, and it has been proposed that all covenants, of whatever nature or for whatever purpose, should, unless a contrary intention is expressed, or may be inferred from the instrument, bind the assignee of terms.

The Law Commissioners also divide covenants where the relation of landlord and tenant, or lessee and reversioner, does not exist, into three classes. 1. Covenants made *with* the owner of the land to which they relate; as covenants for title, to indemnify from existing charges, for farther assurance, &c., which supply the old remedy of warranty, with the difference, that pecuniary damages, instead of the recompense of land, are obtained under them. 2. Covenants made by the owner of the land to which they relate; as to build on certain land, to keep up a road, to keep a space of ground open. 3. Covenants relating to the production of writings and title-deeds; as in cases where an estate is divided into fractions and sold to different persons, one of the purchasers, usually the purchaser of the most valuable share, holding the deeds and writings. It has been contended that a covenant by the owner of land respecting the land should always run with the land; but this doctrine has not been established, and if sanctioned, might give an injurious control over property for an indefinite period. A covenant entered into by a purchaser of land for himself, his heirs, and assigns, not to use the land purchased for certain purposes, as for instance to abstain from building on it, has been held *in equity* to bind all succeeding purchasers who have notice of the covenant. (*Tulk* v. *Moxhay*, 11 Beav. 571.)

At common law, none but parties or privies, by contract or estate, could take advantage of covenants, or be bound by them. Upon the dissolution of monasteries, great evils were found to follow from this state of the law, the lands then seized by the crown, and afterwards transferred to patentees or grantees of the crown, being leased under covenants, which ceased to be binding by the absence of any privity between the lessees of the church lands and the new owners of such lands. To correct these evils the 32 Hen. VIII. c. 34, was passed, which gave to the grantees of reversions generally, and to the grantees and patentees of the crown, the same advantages and remedies as were possessed by the original lessors or grantors of the land. The statute placed the parties to whom it applied in the position of those who were privy to the original contract. To covenants, however, merely collateral, the statute does not apply; that is, if the covenant is beneficial to the lessor, without regard to his continuing the owner of the estate, it is a collateral covenant, upon which the assignee of the reversion cannot sue. The assignee of the reversion, however, is entitled to the benefit of all covenants entered into by a lessee with the lessor, his heirs and assigns, provided such assignee be the owner of the reversion immediately expectant on the term, and provided the estate he has be the same estate which, or a portion of which, the lessor had at the time of granting the lease. If there be a title paramount by escheat or otherwise, the covenant is at an end, if such title defeats the lessor's estate.

It was a common practice, in order to secure the performance of a covenant, to take a bond as an additional security. It enabled the obligee to elect between an action of debt for the penalty of the bond, or to proceed upon the covenant. The reason of the practice was, that at common law a devisee of the real estate of the covenantor was not liable to an action for a breach of covenant, though by the statute of fraudulent devises (3 Will. and Mary, c. 14), he was liable to an action for breach of the condition of the bond. This is now remedied by the 1 Will. IV. c. 47, which extends the provisions of the 3 Will. and Mary to the case of a covenant.

By the 3 & 4 Will. IV. c. 42, actions on covenants must be brought within twenty years after the cause of action has arisen.

Covenants may be discharged by a release, by their performance, by the destruction of the seal, or by the destruction of the interest upon which the covenant depends. They may be void at the time of their creation upon account of the personal incapacity of one of the parties to contract, as being an idiot or a lunatic, or upon account of their object being illegal, as relating to bribery, gaming, illegal insurances, lotteries, sales of offices, simony, smuggling, stock-jobbing, usury, or to wagers. They will also be void if opposed to public policy, as not to trade generally, though a covenant not to trade in a particular place, or with a particular person, would be valid.

COVENANTERS. [Cameron, Richard, in Biog. Div.]

COVERED-WAY, a road surrounding a fortified post along the side of the ditch which is opposite to the ramparts. It is usually about 30 feet broad, on the level of the natural ground, and is protected by the mass of earth called the glacis. Its situation is indicated by the unshaded space above the line R R in the article Bastion (*fig.* 1). As the works of a fortress form a series of angles which are alternately re-entering and salient, the covered-way necessarily changes its direction at each angle; and the spaces which are there formed by its branches (as at L and above the curve line at E in the article and figure above cited) are respectively designated "re-entering and salient places of arms."

Under the name of *orlo* the covered-way is met with in the writings of the first Italian engineers, and it is said to have been invented by Tartaglia in the 16th century.

In the defence of a fortress this work is of great importance. A constant fire may be kept up from thence while the trenches of the besiegers are being slowly executed on the surface of the glacis; and in the systems of Vauban and Cormontaingne it is purposely made so narrow as to render the construction of a breaching battery upon it impossible, except by the tedious operation of removing a large part of the glacis.

The covered way also affords the besieged opportunities of forming under cover, from which they can issue in large bodies for a sortie with an extended front, and having accomplished their object, or been driven back, retire to and cover their re-entry into the place while defiling through the narrow posterns and crossing the ditch, of necessity a work of time. Without the covered-way, troops making a sortie would, after having crossed the ditch, be scarcely capable of deploying under the fire of the enemy; and, in retreating, if pursued, they might be cut in pieces on the counterscarp before they could descend into the ditch, or gain, by the bridges, the posterns of the fortress; whereas by the sally-ports, or by steps temporarily formed along the interior side of the glacis, the departure from, or the return to, the covered way is readily accomplished by a large body of troops.

An attack on the covered-way is, moreover, a difficult enterprise, and is usually attended with great loss to the besiegers; the thickness of the glacis renders it impossible to facilitate the assault by forming a breach in it; a grazing fire of musketry from the covered-way disorders the assailants during their approach; and, when arrived at the crest of the glacis, one, and sometimes two, rows of palisades form a serious impediment to a descent into the work. Even if an entrance should be gained, the assailants are confined between the traverses and annoyed by the fire of the defenders who have retired behind them, or by a plunging fire from the parapets of the fortress. It is easy to conceive, therefore, that such an attack will scarcely be made unless those fires have been previously in part silenced, and the palisades in the covered-way deranged by a fire of guns or howitzers from the enfilading batteries.

COVERTURE. [Wife.]

COW, one of the most useful of the domestic animals. Her milk is peculiarly adapted to nourish infants and invalids, and requires no preparation to make it palatable or wholesome. In the article Cattle, we have given an enumeration of the various breeds of cows; and under Butter and Cheese an account of their principal produce. We shall here confine ourselves to the proper management of a cow, so as to make her most productive; and to the most common diseases to which this animal is subject.

Where only one or two cows are kept, especially where they are to be maintained on a limited portion of pasture, it is of great importance that a good choice be made when they are purchased or reared. Some breeds no doubt are much superior to others; but as a general rule, there is a better chance of having a profitable cow, if she be reared on the land on which she is to be kept. When the common breed of the country is decidedly inferior, it may be profitable to bring a cow from a distance, in which case it should be from some district of which the pasture is rather inferior to that to which she is brought, or at least not better. The best breeds are found in the richest pastures, but they do not thrive on worse. On poor land a small active cow will pick her food and keep in condition, where a fine large cow would starve, or at least fall off rapidly. This is particularly the case in the mountains, near the tops of which no domestic animal will live but the goat, and next to it the smallest breed of cows. Where the pastures are poor but extensive, cows give little milk, and the number which can be kept must make up for the produce of each. Where, on the other hand, cows are stalled, as in Flanders, and fed on artificial food brought to them in sufficient quantity, large bulky cows give the best return for the food; at least, this seems to be the opinion of the Flemish farmers in general. In France, where the cows are led along the roads to pick up the herbage growing by the road-side, or are tethered on a small portion of clover or lucern, a small lean cow is preferred; and in general the cows commonly met with, and which are bred in each district, seem the best adapted for the mode in which they are fed. Whatever be the breed or quality of a cow, she should always have plenty of food, without which no considerable produce in milk can be expected. This food should be succulent as well as nourishing, or else fat will be produced instead of milk. A cow well fed may be safely milked till almost within a month of her calving. It is better that she should be dry before the new milk begins to spring in her udder. A little attention will readily prevent her becoming dry too soon, or being milked too long. Heifers with their first calf should be allowed to go dry sooner than older cows; because their growth would be impeded by the double drain of the milk and the calf. It is best to let a heifer go to the bull when nature prompts her to it, provided she be not less than fifteen or eighteen months old; for if they are thwarted in their first heat, they are apt to become irregular ever after; and it is advantageous for a cow to calve regularly at the same season of the year. The best time is May, when the grass begins to be succulent. In some countries, such as Switzerland, the cows calve regularly in April or May, and are then sent to the pastures among the mountains. The calf is killed almost immediately, unless it be reared for stock, veal being of little value. In populous countries where veal is considered a luxury, the calves are kept and fattened by letting them suck the cows, or by giving them warm milk to drink. Near large towns this is a profitable mode of employing the milk, when it cannot be sold for immediate consumption.

A cottager with two or three acres of moderate land may keep a cow, and thus add much to his earnings as a labourer. For this purpose he will require a small portion of permanent grass fenced off, to allow the cow to take exercise, which is necessary to her health. Her food must be raised in regular succession, and cut for her. The earliest green food is rye; then tares; then clover, which may be made so to succeed each other as to give an ample supply. Cabbages, beet-root, parsnips, potatoes and turnips will continue the supply during winter; and the dung and urine of the cow carefully collected, will be sufficient to keep the land in condition. This system, when lately introduced into some parts of Ireland, greatly improved the condition of the industrious poor. There is very good advice on this management in Cobbett's 'Cottage Economy,' a useful little publication.

Where cows are allowed to be in the open air, with proper shelter in case of stormy and wet weather, they are subject to few diseases. They must be carefully looked to at the time of calving, but except in urgent cases nature must be allowed to perform her own office. A little common sense and experience will soon teach the possessor of a cow to assist nature, if absolutely necessary; and in case of difficulties the safest way is to call in an experienced person. Drinks and medicines should be avoided; a little warm water, with some barley or bean meal mixed with it, is the most comfortable drink for a cow after calving. The calf, and not the cow, should have the first milk, which nature has intended to purge its intestines of a glutinous substance which is always found in the new-born calf. A very common disease with cows is a disordered function of the liver, producing a yellowish tint in the eyes, and sometimes in the skin. A gentle purge, consisting of half a pound of Glauber salts, an ounce of ginger, and two ounces of treacle, with two quarts of boiling water poured over them, may be given when it is milk-warm, and repeated every other day; keeping the cow warm, if it be in winter, by a cloth over the loins, and in a shed. This will in general restore her health. Should the cow appear to have a chronic affection, the safest course for a cottager is to part with her at any price to those who may be better skilled in curing diseases; for it is seldom that a cow is worth the expense of the farrier's attendance in such cases. The symptoms of a diseased liver or lungs in a cow are leanness, with a staring coat, a husky cough with loss of appetite, a difficulty of breathing, and a great diminution in the secretion of the milk. The first loss by the sale of the cow is always the least in the end. In accidents, or acute diseases, the attendance of a clever veterinary surgeon is indispensable.

Nothing is more prejudicial than the idea that medicines are necessary to keep cows in health; and the practice of keeping advertised medicines at hand to give to an animal whenever it is fancied to be ill, is very detrimental to their health. Attention to food and exercise, giving the first regularly and in moderate quantities at a time, and allowing the cow to use her own judgment as to the latter, are the great secrets of health; and a healthy young cow reared at home, or purchased of a conscientious dealer, will probably live to old age without ever having had any disease. A cow is old and unprofitable when she reaches twelve or fourteen years. She should then be sold and a young one purchased. If the cottager have the means of rearing a cow-calf to succeed the old mother, he will do well; if not, he must lay by a portion of the cow's produce every year to raise the difference between the value of the old cow and a young one. The saving banks are admirable institutions for this purpose: a few shillings laid by when the produce of the cow is greatest, will soon amount to the sum required to exchange an old one for a younger.

Calf.—The rearing and fattening of calves is a very important part of rural economy, and on the care with which this is done depends much of the profit of grass-land in particular situations. In the dairy districts the milk is so valuable, that calves are got rid of as soon as possible. In some countries they are killed when only a few days old, and the flesh is of little value, being very soft and tasteless. In others the flesh of very young calves is considered unwholesome, and penalties have been imposed on those who kill a calf before a certain age. This is the case in France and Switzerland, where ten days is the earliest time at which a calf is permitted to be killed for sale.

Wealth and luxury have introduced a very different mode of proceeding in England. Calves are suckled with great care, and allowed to take as much milk as they can swallow, in order to make them fat, and their flesh white, firm, and delicate. The price at which a fat calf is sold, when ten or twelve weeks old, is often much greater than he would fetch at twelve months, if reared in the common way. It is chiefly in the neighbourhood of large towns that the practice of fattening calves is profitable. The calf-dealer buys calves in the dairy districts, and sells them again to those who suckle them. The animals are carried to a great distance in carts made purposely flat and shallow, their four feet tied firmly together, and their heads hanging over the back and sides of the cart. In this position they remain whole days without food or drink, and when they arrive at the place of sale they are so weak and attenuated that many of them die; and all of them require the greatest care and attention for several days before they recover sufficient strength to bear their natural food. If they are allowed to satisfy their appetite at first they invariably *scour*, that is, purge violently, and die. If the strong astringent medicines sold in the shops for the scouring in calves is given to them in this weak state, it only accelerates their death. The best remedy is to boil the milk for them, and give them little at first; to mix some starch or arrowroot with it, and to give them a raw egg beat up in milk. This restores the strength of the stomach, and generally cures them. When the calf begins to thrive on the milk which he sucks, or which is given him warm from the cow, nothing more is necessary than to keep him extremely clean and dry, to give him plenty of air, but not much light, and never to disturb him between his meals, which are generally twice in the day, at the usual time of milking the cows. Where it can be conveniently done, it is better to let them suck three times a day. If one cow does not give sufficient milk to satisfy the calf when he begins to get large, another cow must be at hand. Where a number of calves are fattened at once, and no butter or cheese is made, the number and age of the calves must be regulated by the number of cows and the quantity of milk which they give, so that there shall be milk enough for all.

The calf-pens should be made like narrow stalls, each for the accommodation of only one calf, just wide enough to allow him to lie down, but not to turn about and lick himself, which, if it become a habit, will much retard his progress in fattening. The bottom of the pen should be paved with brick, and washed clean morning and evening—or it should be boarded; the boards should be six inches from the ground, and have holes bored in them to let the urine drain through. A piece of chalk or powdered limestone is frequently put in a small trough, which the calf licks, and thus corrects the acidity which is apt to generate in the stomach. The common notion that it makes the flesh whiter is a mistake, except so far as good health in the calf produces whiter flesh. At five or six weeks old, if a little sweet hay is tied in a small bundle with a string and hung before them, they will pick a little of it; and by thus exciting the saliva the digestion will be assisted. It is only by minute attention that the suckling of calves can be made more profitable than the making of butter or cheese. When it is well managed, and the price of veal is about one-half the price of butter by the pound, there is an advantage in suckling, but otherwise making butter is more profitable.

Calves should be fat by eight or nine weeks old, and it is seldom advisable to keep them above twelve weeks. When they get large they take a much greater quantity of milk, in comparison with what they do at seven or eight weeks old, to produce the same increase of flesh. A calf of 16 or 18 stones (8 lbs. to the stone) the four quarters, and well fatted, will always sell better than one that is larger.

When milk is scarce, and the calves have not enough to satisfy them, it may be necessary to give them some substitute, such as meal mixed with warm milk, or balls of meal and water with a little gin in them, which makes them drowsy. Linseed made into a jelly with boiling water and mixed with warm milk is given by some, or powdered oil-cake. All these substitutes can only be recommended when the milk fails—they deteriorate the flesh more or less. The best plan, in such a case, is to sell the largest calves and reduce the number, so that they may all have their fill of milk. The weight of the four quarters of a calf when killed is about six-tenths of its live weight. Thus if a live calf weighs 200 pounds, his four quarters when he is killed will weigh $20 \times 6 = 120$ pounds.

When calves are intended to be reared for grazing or for the dairy, the most perfect individuals should be chosen. They should be well examined, especially the cow calves, to ascertain whether they have a perfect udder and teats, a broad pelvis, and good lungs. If any deficiency appears, they ought to be sold or fattened. They should be allowed to suck the mother three or four days, but no more, and then be taught to drink milk out of a pail. This is soon accomplished by gentleness and care. Should there be any difficulty in teaching him to suck with the hand in the usual way, a wisp of twisted straw is put into the pail and one end of it in his mouth. This seldom fails to bring him to drink. When the calf is a week old, skimmed milk which has been boiled and allowed to cool again, so as to be milk-warm, may be given him. After a time this may be diluted with water, and a little meal stirred into it; or some thin gruel may be made to which skimmed milk is added. Carrots or turnips make an excellent food for calves, especially if they are boiled with cut hay and given warm. In this way calves may be reared with very little milk, till they can live on grass alone. A bull-calf not intended to be kept as a bull, may be castrated when three months old.

The diseases of calves are chiefly *scouring* and *constipation*: for the first, if the calves are strong, a recipe recommended by Clater, consisisting principally of prepared chalk, is likely to be of service: a large table-spoonful of the powder is given in a pint of new milk every night and morning before the calf is fed, until the purging ceases. For costiveness the following is a good and safe remedy: Castor oil one ounce, prepared kali half a drachm, ginger in powder one tea-spoonful. Mix these for a dose, and give it in half a pint of warm milk.

COWPOX. [SMALL-POX.]

COWRY SHELLS are called by conchologists *Cypræa*. Their beauty has procured them a place among the ornaments of our chimney-pieces, and they have been in demand among civilised and uncivilised nations time out of memory. Like the precious metals, they are not only used for ornament, but they have also the qualities necessary to constitute them a species of currency. In fact, cowries (the *Cypræa moneta*) are used as small coin in many parts of Southern Asia, and especially on the coast of Guinea in Africa. Their great multiplication in these countries, and the extension of the knowledge of coin, has, however, depressed their value so much that they are now used only for domestic interchange, or for the purchase of trifling articles of less value than any European coin. [MONEY.]

The shells used as currency occur principally in the Philippine Islands, and on the coast of Congo, but particularly among the Maldive Islands, of which they constitute the principal article of export. They are fished for three days after the high tides, by the women, with baskets, in which they take up a quantity of sand containing cowries. When the sand is washed out, the shells are heaped up on the shores, and the fish soon die; they are then ready for the market. [CYPRÆIDÆ, in NAT. HIST. DIV.]

CRAB. A machine used in building operations, for hoisting heavy loads. It consists of a wooden frame, forming a wide base able to be weighted in such a manner as to keep the machine steady; and of vertical side frames, which are usually of open cast-iron work, and which carry the seats or bearings for the barrel and winches, set in motion by means of double handles on the end of the winch shaft. The winch is, in fact, a pinion gearing into a toothed wheel, with either a single or double purchase, upon the edge of the barrel wheel: and around the latter the fall, or chain, which raises the load, usually by the interposition of a series of blocks, is wound. Single purchase crabs are rarely able to lift more than two tons; whilst the ordinary double purchase crabs, worked by four men at the wheel, are able to lift as much as from six to eight tons by passing the fall through a series of one, two, and three sheaved blocks.

CRADLING. A wood, or iron frame intended to receive and bind together the materials used to form a solid bed, or landing; occasionally also cradlings are used to support groined arches, but the principle on which they act is in all cases to form, as it were, the skeleton around which the detached materials are made to adhere to one another. The joists of wrought iron, subsequently filled in with cement concrete, which have lately been used to form fire-proof floors, serve actually as cradling; and the iron frames used by the French builders in the construction of their pottery floors and roofs, serve the same purpose. The mode of constructing a cradling must of course depend upon the load it will have to carry, the materials of which it is composed, and the position in which it is placed; and the only general practical remark to be made on the subject is that attention must be paid to obviate any inconvenience from the expansion of the various materials employed, whether that expansion arise from heat, or from the mere crystallisation of the mortars, cements, or plasters. (See Eck. 'Traité de Construction en Poteries et Fer,' Paris, 1841; 'Papers of Royal Inst. of Brit. Architects,' January, 1854.

CRAMP. [SPASM.]

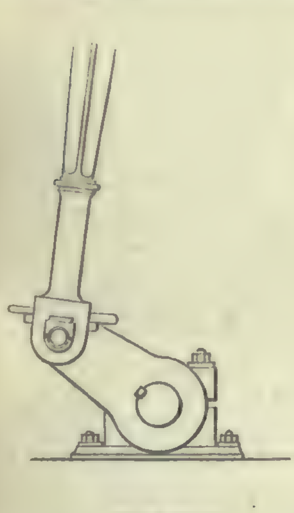
CRAMP. A small piece of metal used for tying together the building materials of large dimensions which cannot be bound by the mere adhesion of the cementitious substances with which they are bedded. Cramps are made of iron, of copper, or of gun metal, and they are run with lead or with sulphur, or cement, according to the position they are used in; their form is either that of a flat piece of metal with the two ends turned downwards, thus ⊓ or it may be simply a flat piece of metal made to present a double wedge on plan thus ⋈. As iron is liable to absorb moisture, even in the interior of a stone, and then to pass into the state of the hydrous oxide, a process always accompanied by an increase of volume, it is advisable only to use iron cramps when the stones they are intended to connect have a considerable thickness; and for thin ashlar work copper or gun-metal cramps should alone be used. In marble works copper cramps are preferable, but they must be run with plaster, or sulphur.

CRANE. A machine used in building, and in ordinary commercial operations for the purpose of hoisting weights. It may be described as consisting of an upright post, bearing a projecting arm or *jib*, usually stiffened by a bracket; and a barrel, winch, pinion, and handles, to receive a fall passed over a sheaf at the head of the jib, and reeved into the block which bears the hook on which the load is ultimately brought. The upright post is, generally speaking, made so as to be able to revolve on its centre, and thus an article raised at any one point may be deposited at any other point within the sweep of the jib. Cranes are made either fixed or movable, single or double; as *pit cranes*, or those which have their foundations below the ground; or as *derricks*, or those which have their framework and stays above the surface.

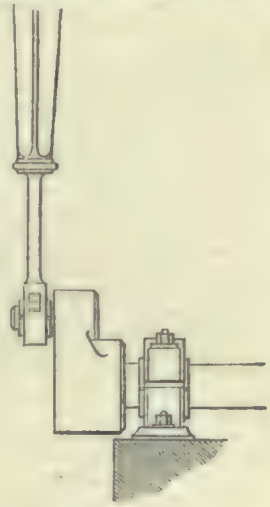
Cranes differ from crabs in this respect, namely, that in consequence of their possessing jibs, the former are able to deposit their load where it may be desired; whereas crabs can only deposit their load vertically, under the last block connected with them.

CRANIOLOGY. [PHRENOLOGY.]

CRANK. A portion of machinery used, together with a connecting rod, for the purpose of converting rectilineal into circular motion, or *vice versâ*. Thus, in an ordinary steam-engine the upward and downward motion of the piston is made to give a circular motion to the crank, by the interposition of the connecting rod, which bears joints at its respective ends; and then the upward motion of the piston causes the crank to pass over half of its circle of revolution, whilst the downward motion carries it over the remainder of its path. Evidently in such an arrangement there must be two points, that is to say, when the piston is respectively at the top and bottom of its stroke, wherein it exercises no power over the crank; and when the crank is upon the horizontal line passing through its own axis the power exercised upon it is the greatest. It is for the purpose of carrying the crank over these dead, or weak points that the fly-wheel is introduced into the construction of engines, and numerous other contrivances have been suggested with a view to reduce or annihilate the irregularity of the action, without, however, producing any practical improvement; so that at the present day the constructors of machinery continue to use the crank and connecting rod in the majority of cases wherein they desire to convert perpendicular into circular motion. In the treatise on the Steam Engine, by Mr. J. Scott Russell, Edin. 1841, the question of the supposed loss of power by the use of the crank is very ably discussed. See also Hann and Gener, 'The Steam Engine,' 8vo, London, 1854; Moseley's 'Mechanical Principles of Engineering and Architecture,' 8vo, Lond. 1843.



[Front view.]



[Side view.]

CRAPE is a light transparent fabric composed of silk, from which, by the mode of its preparation, all the gloss has been taken. When dyed, as it usually is, of a black colour, it is worn as a material for mourning dresses.

The weaving of crape is conducted at a hand-loom, according to the simplest method of the weaver's art: all its peculiarity being given to it in the dressing, which it receives after it is taken from the loom. The silk is used without having been washed or dyed, and consequently with all the natural viscid gum which forms a part of its composition as spun by the worm. For thin crape, the only preparation which the filaments undergo previous to the weaving is the simple twisting, which forms the first process of the throwing mill, and in which state the thread is technically called *singles*. When it is intended to make a more substantial fabric, the warp is formed of two and sometimes three filaments twisted together, which in that state are called *tram:* the weft is still composed of singles. After the web is taken from the loom, it is dressed with a viscid solution of gum, which in drying causes the individual threads to resume, as far as the interlacing will admit, the form they originally held previous to their being twisted in the throwing mill; it is by this means that is produced the peculiar wrinkled appearance by which crape is distinguished. This fact will be shown if a piece of crape is washed in water hot enough to discharge the gum, when the web will resemble thin gauze.

CRAYONS (from the French *crayon*, derived from *craie*, chalk) are a species of material for drawing. They may be classed in two kinds, native and artificial. The principal native crayons are black, white, and red. The best black is procured from Italy. It is a species of earth, which is soft in the ground, but hardens on exposure to the air. It is of a bright even tint, and of a smooth and moderately hard texture. Admirably adapted to outlining and shading drawings of any size, it is to the artist an excellent tool for study. It will form a large, bold, and strong line, and is at the same time capable of great fineness. The best white is a pure chalk, and is procured in France. It is of a brilliant colour, but very brittle; so that it is difficult to avoid breaking it frequently. There are various modes of correcting its brittleness, such as soaking it in milk, baking it on hot iron, or in the fire; but they all, more or less, injure the brilliancy of its tint. Pipeclay is sometimes employed as a substitute, as being smoother and less brittle; but it is of a very inferior tint. White chalk is used on tinted paper to touch on or hatch the high lights. It is also much used by the painter to determine or correct his outline. Red chalk is employed in the place of black chalk on white or tinted paper, because it is freer than the best black chalk, and firmer and smoother than the inferior kinds. It is also of a warmer and more agreeable tone of colour; but it is by no means capable of the same degree of fineness in small or highly finished drawings; it is a clayey ochreous substance. All these three kinds of native crayons are frequently combined in the same drawing, on tinted papers, which are generally of a neutral gray, of a bluish, greenish, or brownish quality.

The native crayons are the legitimate materials for the artist in the study of drawing, and in tracing the first thoughts of design. Some of the sketches of Raffaele, Michel Angelo, the Caracci, and others of the great painters, remain to attest the utility of crayons in forming the style of a painter or sculptor, and their capability of expressing the highest qualities of design.

Artificial crayons are composed of different coloured earths, and other pigments, rolled into solid sticks with some tenacious stuff such as milk, common gin, or beer-wort. The best are procured from Switzerland; but very excellent academy crayons are made in this country, and in Germany. Those made in Germany are most suited to large works, such as studies for fresco paintings, &c. Artificial crayons are employed in crayon painting upon a ground composed of paper or vellum, stretched upon a canvas, which has been previously extended on a deal frame. It is requisite to paint with cooler tints in crayons than in oils, which is the reason why crayon painters generally fall into such a cold style of colouring when they work in the other material. Great softness and delicacy and great vivacity of tint may be obtained in finished crayon paintings; but depth, richness, and truth of colour, are not obtainable, nor solidity in the forms. Moreover, the delicacy proper to the substance is tolerably certain to betray the artist who devotes himself solely to its use into a petty and weak style of drawing. For sketches of portraits, in which the form and expression, and a general idea of the complexion, are all that is required, crayons are a pleasing and useful material; but they should be employed only occasionally, and as a variety to other modes of study.

Considered as a branch of manufacture, crayons, as we have stated above, have been more carefully attended to by the French than the English. There are many recipes for the preparation of them: spermaceti, bone-ash, and boiling water; pipeclay, prepared chalk, colouring matter, and pale mild ale; white soap, rectified spirits of wine, washed clay, chalk, colouring matter, and boiling water; pure clay, shellac, spirits of wine, oil of turpentine, and colouring matter; fine pale blue clay, shellac, wood naphtha, and colouring matter: all are recipes in practical use. The colouring matter differs greatly in kind; mere difference of *tint* is produced by diluting with washed chalk; but difference of colour depends of course on the pigment mixed with the substance of the crayon. Thus, for black, are used black lead, ivory black, and lamp black; for blue, indigo, smalt, verditer, and Prussian blue; for brown, umber and terra di Sienna; for green, mixtures of blue and yellow; for yellow, king's yellow, Naples yellow, orpiment, and yellow ochre; for red, carmine, vermilion, hæmatite, red chalk, and red lead; for purple, blue mixed with carmine or vermilion. In making crayons, the manufacturers generally employ a metal cylinder, two or three inches in diameter, open at one end and having a perforated bottom at the other. The perforations are equal in size to the intended thickness of the crayon. The composition, in the state of a stiff paste, is put into the cylinder, and is forced down by a plug or piston; it exudes through the holes, and is cut off into convenient lengths.

Crayons for writing on glass are made of French chalk; or of a mixture of spermaceti, tallow, wax, red lead, and carbonate of potash. Crayons for writing or drawing on stone are made of two or three different mixtures: tallow, soap, white wax, and lamp black; tallow soap, white wax, shellac, and amp black; white wax, spermaceti, hard soap, and lamp black; &c.

An instrument called a portcrayon is employed to hold the crayon by. It is a metal tube, split at each end, so as to gape a little to admit the crayon; a sliding ring embraces the tube, and may be made to close the disparted sides firmly upon the crayon.

A stump, made of leather, cork, or paper, closely rolled, or cut into a short round stick, more or less sharply pointed at each end, is used to soften and spread the chalk or crayon in the shaded parts of the drawing.

CREAM. [BUTTER.]

CREAM OF TARTAR. [POTASH, *Bitartrate of.*]

CREAMS. Creams, in the language of the confectioner, are compounds of cream, or sweetened water, or egg and milk, with various flavouring vegetable juices, congealed by ice, or by a freezing mixture. The flavouring agent may be almond, chocolate, coffee, lemon, orange, pistachio, raspberry, taraxacum, vanilla, &c. Ices, creams, and ice-creams differ a little in their mode of preparation, but scarcely at all in their ingredients.

CREASOTE or **KREASOTE** ($C_{16}H_9O,HO$?) (from *κρέας*, "flesh," and *σώζω*, "to save,") is a fluid compound of oxygen, hydrogen, and carbon, obtained by Reichenbach. This substance exists in crude pyroligneous acid, but it is best prepared from that portion of the oil distilled from wood-tar which is heavier than water. The operation is too complicated to admit of its being stated at length. The properties of creasote are the following: It is a colourless transparent fluid, and has a strong odour which greatly resembles that of smoked meat, with a caustic and burning taste. Its specific gravity is 1·037; it boils at 397°, and remains fluid at 17° below zero. It requires 80 parts of water for solution, and is soluble in alcohol, ether, and sulphuret of carbon, in all proportions. It burns with a sooty flame, refracts light powerfully, and is a non-conductor of electricity; it has neither acid nor alkaline properties. It is highly antiseptic, and hence the name given to it. It combines both with acids and with alkalies; but it is decomposed by strong nitric and sulphuric acid.

Creasote coagulates albumen, even when much diluted, and it also coagulates serum. Meat and fish are preserved after having been brushed over with creasote and dried in the sun; the antiseptic power of pyroligneous acid and wood-smoke is supposed to be derived from its presence. A few drops added to ink are said effectually to prevent its becoming mouldy.

CREASOTE or **KREASOTE**, *Medical Properties of.* The chemical formula shows that creasote contains a very large proportion of carbon; which circumstance, along with other peculiarities, renders it in certain cases a valuable medicine, and in other instances a formidable poison. The introduction, by its means, of a large quantity of carbon into the body, produces all the bad effects which an excess of that principle in the animal system is known to occasion; while in certain morbid states of the system, this increased quantity of carbon produces the remarkably sedative effect which has followed its use. There can also scarcely be a doubt that the highly carbonised nature of this compound, along with its power of coagulating albumen, is the source of the powerful antiseptic properties which many of its combinations and solutions have been known for ages to possess. Independently of its general action on the system when taken internally, it produces, when concentrated, a local effect on the part to which it has been applied very necessary to be borne in mind, and which probably is owing to the power which creasote seems to possess of coagulating the albumen, even of living as well as of dead tissues, and which it is enabled to reach by destroying the epidermis of the part which it has been allowed to touch. Dropped upon the tongue it causes violent pain; unless largely diluted it cannot be swallowed, as, independent of the pain, it coagulates the albumen of all the fluids with which it comes in contact. Fibrine, carefully separated from other principles, is not affected by creasote.

A few drops of a very dilute solution of creasote taken into the stomach causes a sensation of warmth, and if repeated at short intervals, or the dose gradually increased, giddiness and other signs similar to those of intoxication are experienced. The urine is frequently observed to acquire a black hue, "as if a small quantity of Indian ink had been added to it, perfectly transparent, and without sediment." ('Medical Gazette,' vol. xvi. p. 599.) In larger doses it has all the effects of a narcotico-acrid poison, the venous state of the blood producing on the brain a markedly sedative effect, and the respiration becoming slow and laborious, or convulsive. Animals, fishes, and insects, plunged into creasote water speedily die with strong convulsions. Even plants watered with it perish, except perhaps those of the tribe Ericaceæ, which constitute the chief vegetation of bogs or mosses. The injurious action of the smoke of towns on plants has been ascribed to the creasote it is supposed to contain. But mechanical impurities have a far larger share, as is proved by the utility of Ward's cases.

Creasote has been recommended as a remedy in very many diseases, in few of which will it ultimately be found useful. Vomiting, including sea-sickness, some forms of bronchitis, cutaneous diseases, and hæmorrhage either spontaneous or from wounds, are the only cases in which it has a claim to confidence. Vomiting, such as frequently occurs in hysterical and other persons from irritation of the origin of the eighth pair of nerves, will almost invariably be alleviated or checked; also that in sea-sickness, which proceeds from a similar cause, may be lessened, but scarcely any other kind of vomiting can be relieved by it. That form of vomiting which occurs towards the end of phthisis pulmonalis, and is connected with subacute inflammation of the stomach, is sure to be aggravated by it; as will any other, either caused by scirrhus, ulceration, or any crude indigested matter in the stomach. The utility of breathing the vapour of tar-water in some forms of bronchitis often mistaken for consumption, has long been known: but creasote can be of no service in true tubercular consumption, when cavities exist in the lungs. Glanders in the human subject has been cured by injections of creasote thrown up the affected nostril. (Dr. Elliotson.) Creasote possesses great influence over external ulcers when it can be applied sufficiently strong to coagulate the albumen and so form an artificial skin, under which the healing process goes on kindly. Thus in porrigo, especially ringworm of the scalp, and psoriasis, it is unrivalled. But poisoning has resulted even from its external application. Its power of coagulating the albumen of the blood renders it a most valuable styptic, and it may be employed to stop the bleeding mouths of even the largest arteries, such as the carotid, during surgical operations, or the flow of blood from leech-bites. In case of poisoning by creasote, moderate venesection and artificial respiration may be employed; the latter should be continued till by the operation of the lungs, the liver, and the kidneys, the system can free itself from the hurtful excess of carbon. The solution of creasote should always be prepared of a definite strength, to prevent unfortunate occurrences from an over dose. Creasote is now extensivily employed to preserve anatomical preparations for museums. It is likewise fraudulently added to whiskey to give the *peet-reek* flavour which many like.

CREATINE. ($C_8H_9N_3O_4 2Aq.$) This body, originally discovered by Chevreul, occurs in transparent very brilliant crystals. It has a bitter strongly pungent taste, and irritates the pharynx. It dissolves in 74 parts of cold water, and in boiling water in such quantity that on cooling the solution becomes consolidated into a mass of glistering needles. It dissolves sparingly in alcohol, and not at all in ether. It forms no definite salts with acids. According to Liebig it is best obtained from finely chopped flesh that has been well kneaded with water, and the fluid removed by pressure. The coagulable matters are then removed by boiling, and the phosphates by caustic baryta. The fluid left is then evaporated till the creatine is deposited in the form of needles. Creatine can also be obtained from the urine. It appears to be produced in the flesh of animals as the result of a process of retrogressive change in the elements of the tissues in which it is found. It is in fact a product of excretion.

CREATININE ($C_8H_7N_3O_2$) was discovered by Liebig. It is obtained from creatine by the action of hydrochloric acid. It is found also in the muscles and the urine, with creatine, whilst these bodies are in their normal condition. But in putrid flesh and urine no creatine is found. Hence creatinine may be regarded as the result of the decomposition of creatine.

CREDENTIALS are the instruments which an ambassador or other diplomatic minister receives from his own government, authorising him to appear in his diplomatic character, defining the extent of his powers, and showing to what rank of ministers he is intended to belong. The credentials are usually in the form of a closed letter, addressed to the power to which the minister is sent; but ministers are sometimes accredited by letters patent, which is the form commonly adopted when they are to be sent to a congress.

A minister cannot be received in any other character than that which is given him by his credentials; and for this reason he usually communicates their contents before he is admitted to his first audience. If he is accredited by letters patent, this is done by showing the instrument itself; but if his credentials are sealed, then by presenting a copy of them.

The powers granted by the credentials may either be confined to certain specified transactions, or extend generally to all negotiations whatever; and may, in either case, be either limited or unlimited; in which latter case the minister is styled a minister with full powers, or minister plenipotentiary.

(Vattel, *Droit des Gens*, liv. iv., § 76; Klüber, *Droit des Gens moderne*, §§ 193, 194.)

CREDIT. [Bill of Exchange; Currency.]

CREDIT, LETTER OF, is an order given by bankers or others at one place to enable a person to receive money from their agents at another place. The person who obtains a letter of credit may proceed on his journey, and need only carry with him a sum sufficient to defray his expenses; he even derives from it some of the advantages of a banking account when he reaches his destination, as he may avail him self of it only for part of the sum named. If it were not for the convenience which a letter of credit affords, a person intending to make a tour, for example, on the Continent, would be under the necessity either of taking with him the whole of the money which he would require during his absence, or of receiving remittances from home, addressed to him at particular places.

This instrument is now subject to a stamp duty of one penny, except when it is sent by a person in the United Kingdom to a person abroad, authorising drafts on the United Kingdom. It is not a negotiable instrument. No one, therefore, can legally demand payment or give a valid discharge for the amount except the person named in it, or his agent duly authorised for that purpose; so that payment to any other is no discharge of the banker from his engagement thereon. At the same time there is no contract of the banker or his agents with the payee, so as to be liable for damages in an action instituted by the payee for having refused him payment, according to the tenor of the letter, unless indeed the payee in one locality happens to be the same person who in another purchased the letter for his own convenience. Where the payee and the purchaser of the letter are different persons, the payee's remedy in such a case is against the purchaser, to whom the banker is answerable for the default of his agents in not meeting the payee's drafts by prompt payment.

CREED, from the Latin *credo* (I believe), the English name for those short summaries of Christian doctrine which in the Continental churches are commonly called symbols, though sometimes, also, credos. The English Church adopts, as "thoroughly to be received and believed," the three ancient creeds, called the Apostles' creed, the Athanasian creed, and the Nicene creed, but only says of them generally, that "they may be proved by most certain warrants of holy Scripture." (Art. viii.) The Roman Catholic Church adopts along with these what is called the Creed of the Council of Constantinople, which contains some addition to what is said in the Nicene creed on the subject of the divinity of the Holy Ghost. Many other similar formulæ have been received at different times in particular Churches.

CREEK is a small inlet on a low sandy coast. Such inlets occur also frequently in harbours inclosed by a low shore and along the banks of rivers. Sometimes, especially in harbours, creeks are formed by the mouths of small brooks and rivulets. In large rivers creeks are resorted to by small craft as harbours or landing places, and they are often visited by fish in spawning time. In the United States the name creek is very generally applied to small *inland* streams, which in England would be called brooks or rivers.

CREEK INDIANS. [North American Indians.]

CREES AND CHIPPEWAYS. [North American Indians.]

CREMO'NA, a general name given to violins made at Cremona in the 17th century by the Amati family, and by Straduarius at the commencement of the 18th. These instruments excel all others, and the choicest of them bear very high prices. [Violin.] Cremona is a name erroneously given to a stop in the organ; it ought to be *Krumhorn*, a sort of cornet, of which it is intended to be an imitation.

CRENIC ACID ($3HO,C_{24}H_{12}O_{16}$). An acid found combined with ammonia in vegetable mould. It dissolves in water with a yellow colour, and, rapidly absorbing oxygen, becomes converted into a brown solution of *Apocrenic acid* ($2HO,C_{48}H_{12}O_{24}$).

CREOLES, a word originally Spanish, and used to designate the children and descendants of European parents, who were born in the South American or West Indian colonies, as distinct from the resident inhabitants born in Europe, as well as from the offspring of mixed blood, such as the Mulattos and Mestizoes, born of negro or Indian mothers. The Creoles of Spanish America were for a long time inadmissible to civil and political offices, as well as to the higher ranks in the army; and even after Charles III. removed their disqualifications, they were still considered as inferior to the native Spaniards. This state of humiliation contributed perhaps as much as the climate to render them lazy and indolent. The insurrection of the Spanish colonies made the Creoles masters of the country, from which the native Spaniards were mostly driven away. In the West India Islands the Creoles are upon an equal footing with European natives. The Creole women are characterised by the symmetry of their persons, the brilliancy of their eyes, and the sallowness of their complexions.

CREOSOTE. [Creasote.]

CREPUSCULUM. [Twilight.]

CREST, from the Latin *crista*, the ornament of the helmet: a term in heraldry sometimes used for the helmet itself. Hence, *to crest*, to adorn as with a plume or crest, in Milton, 'Par. Lost,' ix. 500.

> "his head
> *crested* aloft."

In speaking of the cimier or crest, says Dallaway ('Inquiries into the Origin and Progress of Heraldry in England,' 4to, Glouc. 1793, p. 386), "It will be necessary to describe the armour worn for the defence of the head, and the progressive embellishments which were added to its rude form, with the era of their invention. Montfaucon, that most critical antiquary, has preserved many delineations of the ancient Norman casque, which, when the whole body was invested in mail, was composed of iron framework, covered with leather, and quite flat at the top, to which shape succeeded the conical head. By the number of bars of which the beauvoir or visor consisted, when presented in front view, the rank of the wearer was ascertained; that of the esquire was always in profile and closed, to denote his vigilance and activity in battle. The date of the introduction of crests into England is uncertain. After the time of Richard I., some of the kings are represented with a crown as a sort of crest on the helmet. The seal of Edmund Crouchback, earl of Lancaster, exhibits the crest, accompanied by the lambrequin and wreath, prior to the year 1286. The crest is said to have been carved in light wood, or made of leather, in the shape of some animal, real or fictitious, and fastened by a fillet of silk round the helmet, over which was a large piece of fringed samit or taffeta, pointed, with a tassel at the end. Before figures were introduced, plumes only were used, as well upon the head of the horse as on that of the warrior, which we gather from the seal of Baron de Spencer in 1296." In 1322, Thomas, earl of Leicester, bore the figure of a dragon. "The principal application of crests was in jousts or hastiludes, when the shield was not borne, but where they afforded an equal distinction; or by the chief commanders of horsemen in the field of battle. . . . . Crests are not held to be absolutely hereditable, but may be assumed; and as females could not avail themselves of their primary use, accordingly no woman is allowed to bear a crest. As an appendage to sepulchral monuments, crests are placed beneath the head of the armed effigy. attached to the helmet by the wreath and lambrequin; and at the feet a lion or dog is added. Upon many of the large altar-tombs, so frequent in the 16th and 17th centuries, those both of the man and of his wife's family are carved at the feet of the recumbent figures." The wreath on which the crest rests was of silk, twisted of different colours, according to the fancy of the wearer. The position of the crest when the arms are blazoned varies with the rank of the bearer. Peers have the coronet on the shield, and the helmet and crest above the coronet. Commoners have the helmet and crest, with the interposing wreath, resting on the shield.

Instances of crests formed of feathers may be seen in that of Sir Henry Percy, in Edward I.'s time, engraved at the bottom of plate xxiv. of Meyrick's 'Critical Inquiry into Antient Armour;' and in that of Sir John Harsick, *t.* Richard II., 1376, in plate xxxvi. of the same work; and many such occur in the illuminations to the contemporary manuscripts of Froissart's Chronicle. The custom of conferring crests as distinguishing marks seems to have originated with Edward III., who in 1333 ('Rot. Pat.,' 9 Edward III.) granted one to William Montacute, earl of Salisbury, his "tymbre," as it was called, of the Eagle. By a further grant in the 13th of the same king ('Rot. Vasc.,' 13 Edw. III. m. 4), the grant of this crest was made hereditary, and the manor of Wodeton given in addition to support its dignity.

CRESYL ($C_{14}H_7$). The hypothetical radical of an alcohol, *cresylic alcohol*, or *hydrate of cresyl* ($C_{14}H_7O,HO$), found in some descriptions of commercial creasote prepared from coal tar.

CRESYLIC ALCOHOL. [Cresyl.]

CRE'TINS, a word of which the derivation has been disputed, but which is probably from the Romanesque *cretina*, a miserable creature; and the various names for the same class, trotteln, lallen, göcken, cagot, &c., all convey a similar meaning. In the Valais and other Alpine valleys, crétins are certain individuals who are more or less idiots, and most of whom have large swellings on their necks, called goîtres. The goître or wen is not, however, always a necessary sign of crétinism. The goîtres are of all sizes, from that of a walnut to the size of a quartern loaf. There are also various gradations of crétins; those in the lowest state of idiotcy cannot articulate distinct sounds, but make a sort of cry, or burst out into an idiotic laugh; they are as helpless as infants, and their intelligence seems below that of many brutes. Others are able to go about, and attend to some easy labour, and make themselves understood. They are numerous about the villages and hamlets of the Lower Valais and of the Val d'Aosta; they are not so common in the German part of Switzerland, where, in many of the valleys they are unknown; it is said that they are not found among the natives of the higher valleys or mountains; even in the Upper Valais, east of Sion, they are rare. Crétinism, however, is not confined to Switzerland, it prevails in Carinthia, in the valleys of the Pyrenees and the Apennines; in the Harz mountains; and, out of Europe, in Tatary, in the Ural mountains, in Bootan, Tibet, Sumatra, among the Cordilleras, and even in Africa, in Bambarra, and along the upper part of the Niger. Isolated cases are met with everywhere. There has been much discussion about the causes of this infirmity. In Germany great attention has been paid to the subject, and Dr. Röson (über Cretinismus und angebornen Blödsinn,' in a discourse delivered before the Natural History Society, at Eslangen, in 1841), attributes it sometimes to the state of health of the parents, but more frequently to atmospheric and climatial causes, and particularly to such sudden changes of temperature and of weather as are experienced in mountain valleys, in which also are commonly found morassy soils or stagnant waters; and above all, the nature of the water which is drunk. Attempts have been made to ascertain the proportions of crétinism on various geological formations; in Berne, crétins are most numerous in the Jura formation; in Austria they are stated to prevail most in those valleys resting on trapp, porphyry, or clay-slate. The disease does not appear to be generally born with the child, though sometimes scrofulous symptoms precede, but to develope itself between the second and sixth years of age, commencing by a softening of the bones, and an ever-increasing fatuity. These symptoms can, it is said, be sometimes removed or alleviated by early applied medical and moral treatment.

In Berne, an institution has been formed at Abendberg, for the reception and instruction, where possible, of the poor sufferers, under the management of its founder, Dr. Güggenbühl; who has contributed an interesting account of his proceedings, and of the various classes of crétinism, to the 'Deutschen Vierteljahrschrift' (Quarterly Journal of Germany), in 1845.

CRIMES AND PUNISHMENTS. The punishments under the criminal law had been greatly mitigated previous to 1840. In consequence of this, and perhaps still more from the establishment of an effective police in the metropolis by Sir R. Peel's Act, the 10 Geo. IV., c. 44, which has been gradually extended to the whole of Great Britain and Ireland, though the number of executions has declined, the number of commitments and the proportion of convictions have increased. In 1831 the number of commitments had been 19,647, of whom 3047 were females. Of these 13,830 had been convicted, and 1601 sentenced to capital punishments. Of these only 52 were executed, 12 being for murder. Up to 1834 there had been no classification of offences. From that year and subsequently they have been classed under the following heads, from which it will be seen that the increase of offences has been, in England and Scotland, chiefly in offences against property without violence: Class 1, offences against the person; 2, offences against property, committed with violence; 3, offences against property, committed without violence; 4, malicious offences against property; 5, forgery and offences against the currency; 6, other offences, not included in the foregoing classes. In 1835 there were 20,731 commitments, of which 2016 were under class 1, 1354 under class 2, 15,478 under class 3, 156 under class 4, 368 under class 5, and 1359 under class 6. Of the total 14,729 were convicted, of whom 523 were sentenced to capital punishment, and 34 executed, of whom 21 were for murder. In 1856, there were in England 19,437 persons committed for trial, of whom 15,425 were males and 4012 females; of these, 4672 were acquitted or discharged, and 31 were found insane; of the number convicted, 1264 were for offences against the person, 1787 for offences against property with violence, 10,487 for offences against property without violence, 94 for malicious offences against property, 757 for forgery and offences against the currency, and 345 for offences not included in the preceding classes, and including misdemeanors; 69 were sentenced to death, of whom 16 were executed; 57 were transported for life, and 216 for terms exceeding ten years; 2158 were sentenced to penal imprisonment for terms varying from four years to life; 11,865 were sentenced to various imprisonments, from one month and under to not exceeding four years; and in this class, in the terms between six months and one month or less, the numbers show a remarkable decrease from previous years; in 1856 the numbers were 7800, against 13,447 in 1855, and 16,509 in 1854; indeed it is by far the smallest amount in any year from 1847; 222 were ordered to be detained in reformatory schools, and 127 were whipped, fined, or discharged on sureties. The great decrease in the number of commitments is probably to be attributed in a considerable degree to the extended provisions of the Summary Convictions Acts. On summary proceedings, the number of cases under the Criminal Justice Act, was 11,272, and under the Juvenile Offenders' Act, 2031. Altogether there were 132,869 persons committed to prison, 99,336 of whom were males, and 33,363 females. The commitments were—19,278 for trial, 77,712 on summary convictions, 2794 for want of sureties, 13,952 remanded and discharged, 11,406 debtors on civil process, and 7557 under the Mutiny Act. The total shows an increase of nearly 4000 commitments over those for 1855: but there is a decrease of 7000 in the number of summary convictions. Of the committals, omitting debtors and military prisoners, which reduce the number to 113,736, 1990 were of children under 12 years of age; 11,991 of persons between 12 and 16; 24,868 between 16 and 21; 33,400 between 21 and 30; 20,973 between 30 and 40; 11,343 between 40 and 50; 5519 between 50 and 60; 2732 above 60; and 920 of whom the age was not ascertained. Of the whole, 37,686 could neither read nor write, 61,253 could read or read and write imperfectly, 6108 could read and write well, 318 had received superior instruction, and of 8371 the instruction was not ascertained. The county and borough prisons are stated to be constructed to contain 26,447 prisoners; the daily average of prisoners is 17,754, and the greatest number at one time was 22,035; but, though on the average there may be room enough, some prisons are terribly overcrowded.

In Ireland in 1856 the total number of persons committed or held to bail for trial was 7009, of whom 3075 were either acquitted or discharged. Of the number committed, 2063 were for offences against the person, 556 for offences against property with violence, 2884 for offences against property without violence, 78 for malicious offences against property, 75 for forgery and offences against the currency, and 1143 for other miscellaneous offences. Of those convicted only 8 were sentenced to death, and 3 only executed; 14 sentenced to transportation for life, and 372 to other periods of transportation or penal servitude; 2798 to various terms of imprisonment; and 832 were whipped or fined, or discharged on surety, or pardoned. In the same year there were 25,461 cases heard at petty sessions or before magistrates, and 9526 persons were imprisoned for drunkenness.

In Scotland in 1856 the total number of offenders committed for trial was 3718. Of these 1046 were for offences against the person, 380 for offences against property committed with violence, 1942 for offences against property without violence, 79 for malicious offences against property, 85 for forgery and offences against the currency, and 181 other offences not included in the preceding classes. Of the total number committed, 2723 were convicted, of whom 3 were sentenced to death and executed, 274 sentenced to various periods of transportation and penal servitude, 2170 to various periods of imprisonment, and 276 to be whipped, fined, or discharged on sureties. Of those not convicted, 35 were outlawed, 7 were found insane, 55 were found not guilty, and 179 not proven; the remainder were discharged without trial.

In 1857 was commenced a more complete report, under the title of Judicial Statistics. In this year the report was confined to criminal statistics, of which the following is an abstract.

Police and Constabulary.—The number and expense of the police and constabulary for every county and town, with their respective divisions, and the cost, are given. The total number in England is 19,187, consisting of 7301 for the various county constabularies, 5251 for borough police, 6083 for the metropolitan police, and 552 for the city of London police. The total cost of this force for the year ended Sep. 29, 1857, had been 1,265,579*l.*; of which 441,569*l.* was for the county constabulary, 337,853*l.* for the borough police, 442,212*l.* for the metropolitan police, and 43,945*l.* for the city of London police. A part of this expense, except in the case of the city of London, is defrayed from the public revenue, there being paid to the county constabulary 71,112*l.*, to the borough police 60,970*l.*, and to the metropolitan police 103,380*l.* In the year there were altogether 401,264 cases of minor offences, assaults, petty thefts, drunkenness, vagrancy, and offences under the Highway Acts, Licensed Victuallers and Beer Acts, Stage-carriage Acts, &c. Of these, 314,432 were by males, and 86,832 by females. Of the total, 369,233 cases were decided summarily by magistrates; 233,759 were convicted, and 135,474 were discharged. The remaining 32,031 cases were the results of 57,273 offences which had come to the knowledge of the police, and of these 17,861 were committed or bailed for trial. Of the total number apprehended by the police, the classification is as follows:—

	Males.	Females.	Total.
Known thieves	18,556	4,546	23,102
Prostitutes	..	24,282	24,282
Vagrants and tramps	14,272	4,998	19,270
Suspicious characters	40,112	6,692	46,804
No known occupations	5,218	1,696	6,914
Previous good characters	112,017	14,548	126,565
Characters unknown and not ascertained	124,257	30,070	154,327
	314,432	86,832	401,264

Of the convictions, the number for assaults was 44,860, for drunkenness 44,894, for theft 20,577, and for vagrancy 18,023.

Criminal Proceedings.—The total number of persons committed for trial in 1857 was 20,269, of whom 15,970 were males, and 4299 were females; of these, 15,342 were convicted: 1442 for offences against the person, 1752 for offences against property with violence, 10,850 for offences against property without violence, 101 for malicious offences against property, 850 for forgery and offences against the currency, and 332 for offences not included in the foregoing classes. There were 54 sentenced to death, of whom 20 were for murder, and of these 13 were executed; the punishment in all the other cases being commuted to transportation or penal imprisonment.

Prisons.—The report notices great improvements in the construction and management of prisons. The number of persons committed to them in 1857 was—

	Males.	Females.	Total.
For trial at assizes or sessions	15,958	4,254	20,212
On summary conviction	62,170	24,625	86,795
For want of sureties	2,318	845	3,163
On remand and discharged	10,631	4,022	14,653
For debt and on civil process	13,499	840	14,339
Under the Mutiny Act	2,808	..	2,808
	107,384	34,586	141,970

Of re-committals for crimes or offences, there were 42,169, of which 18,374 had been previously committed once, 8128 twice, 4400 thrice, 2970 four times, 1857 five times, 2276 six and seven times, 1700 eight to ten times, and 2464 above ten times. Of the commitments, 1877 were of children under twelve years of age, 10,624 were between twelve and sixteen, and 29,949 were between sixteen and twenty-one. Omitting prisoners for debt, and the military, there were 124,823 persons in confinement, of these 97,054 were English, 2903 Welsh, 2399 Scotch, 18,067 Irish, 652 from British colonies and the East Indies, 2016 foreigners, and 1732 not ascertained. Of the whole, 44,291 could neither read nor write, 72,387 could read or read and write imperfectly, 6348 could read and write well, 409 had had a superior education, and

1388 were not ascertained. The amount of prison accommodation is stated to be sufficient on the average; but some of the prisons of populous places are occasionally over-crowded—such as Middlesex, Westminster, Wandsworth, Durham, &c. The daily average number of prisoners was about 19,686, and the total cost for the year was 567,804*l.*, but this includes 120,799*l.* expended on new buildings, alterations, and repayments, leaving 447,004*l.* as the ordinary annual charge for prisoners, an average of 23*l.* 10*s.* 3*d.* for each, divided thus: —for repairs, furniture, &c., 5*l.* 0*s.* 5*d.*; for officers' salaries, pensions, &c., 9*l.* 17*s.* 8*d.*; for prisoner's diet, clothing, medicine, &c., 8*l.* 12*s.* 2*d.*

The government prisons now provide for the treatment of convicts sentenced to long terms of detention, the great proportion of whom it had been the practice to transport to the penal colonies, or to confine on board the hulks. They are:—

"1. The Millbank prison, now chiefly used as a general receiving prison and depôt for convicts of both sexes, including a penal class for both, but appropriated also in part for a class of females undergoing the first stage of their punishment.

"2. The Pentonville prison, adapted for the preliminary period of separate confinement and instruction of adult male convicts.

"3. Portland prison, for able-bodied male convicts undergoing the second stage of their punishment, and employed upon the public works.

"4. Dartmoor prison, principally for infirm and sickly male convicts, who are employed in farm labour, and partly in manufacture.

"5. Portsmouth prison, and 6, Chatham prison, for able-bodied male convicts in the second stage of their punishment, who are employed in the heavy unskilled labour of the naval yards and arsenals.

"7. Brixton prison, exclusively for females in the second stage of their punishment, employed in needlework and the domestic labour of the prison.

"8. The hulk 'The Stirling Castle,' at Portsmouth, used chiefly as a receiving ship for prisoners sent from the convict establishments at Gibraltar and Bermuda for release in this country, and for a small number of invalid prisoners.

"9. Parkhurst, used as a reformatory for boys, who are employed in farm labour, and partly in manufacture.

"10. Fulham Refuge, for females under reformatory treatment in their second stage of discipline."

In these various prisons, there were at the commencement of 1857, male prisoners 6171, females 830, and 6236 males and 758 females were received during the year; of the whole, 1032, all males, were sent to Western Australia, Bermuda, and Gibraltar; 2871 males and 333 females were removed from one prison to another, including those removed from the abolished hulks, and removed to lunatic asylums; and 178 females were sent to reformatories; 162 males and 6 females were discharged on the termination of their sentences; 836 males and 86 females were discharged on tickets of leave; 9 males on commutation of sentence; 53 males and 15 females were pardoned; 68 males and 17 females died; 2 males committed suicide and 6 escaped; a total of 5675 disposed of, and 8320, of whom 7368 were males and 952 felmaes, remained in the beginning of 1858.

Crime in Ireland.—In 1857 the total number of persons committed or held to bail was 7210, of whom 3285 were not convicted. Of the number committed, 5458 were males and 1752 were females. Of the number convicted, 1036 were for offences against the person; 314 for offences against property committed with violence; 1641 for offences against property without violence; 61 for malicious offences against property; 57 for forgery and offences against the currency; and 1816 for other miscellaneous offences. Only 6 were sentenced to death; and none were executed; 40 were sentenced to transportation, 396 to penal servitude for various periods, 2674 to various terms of imprisonment, and the remainder whipped, fined, discharged on sureties, or pardoned. In the year there had been 23,563 summary convictions before magistrates or at petty sessions, and 9,557 committals for drunkenness.

Crime in Scotland.—In 1857 the total number of offenders committed for trial or bailed was 3840, of whom 2743 were males and 197 females. Of the whole, 920 were acquitted on trial, discharged without trial, or found insane. Of those convicted, 1140 were for offences against the person, 408 for offences against property committed with violence, 1903 for offences against property committed without violence, 53 for malicious offences against property, 89 for forgery and offences against the currency, and 207 for other offences not included in the foregoing classes. Of the total, 557 males and 316 females could neither read nor write; 1625 males and 697 females could read and write imperfectly; 467 males and 75 females could read and write well; and 82 males and 7 females had had a superior education; 14 are unaccounted for. Of the punishments, 3 were sentenced to death and executed for murder; 28 sentenced to various periods of transportation; 230 to various periods of penal servitude extending from three years to life; 460 to various periods of imprisonment from three years to more than six months; 1877 to imprisonment for six months and under; and 287 to be whipped, fined, and discharged.

In 1859 the plan was more completely carried out. We give the statement below of the crimes and punishments of 1858; but the returns of the Civil Procedure do not come within our limits, and we therefore confine ourselves to the criminal returns:

Police and Constabulary.—The number and expense of the police and constabulary for the whole of England and Wales, were 20,256 men (including the chief officers and other officials), and 1,447,019*l.* The borough constables, appointed by watch committees were 5804; the county constables, 7549; the metropolitan police constables, 6295; and the city of London constables, 608. The salaries and pay amounted to 1,081,748*l.*; allowances and contingent expenses, 41,824*l.*; clothing and accoutrements, 106,097*l.*; superannuation and gratuities, 55,386*l.*; horses, harness, forage, &c., 29,609*l.*; station-houses, charges, printing, &c., 108,896*l.*; other miscellaneous charges, 23,459*l.* The borough police cost 366,207*l.*, of which the treasury paid 70,528*l.*; the county constabulary cost 553,483*l.*, of which the treasury paid 99,774*l.*; the metropolitan police cost 480,736*l.*, of which the treasury paid 113,338*l.*; and the city of London police cost 46,593*l.*, the whole defrayed by the city.

The investigations of the police have ascertained more precisely than had ever been done before, the real numbers of the criminal classes. The report states that in 1858 there were:—

		Males.	Females.	Total.
Known thieves and depredators,	under 16 .	4,773	1,608	6,381
„	over 16 .	26,772	6,879	33,651
Receivers of stolen goods,	under 16 . .	119	29	148
„	over 16 . .	3,410	787	4,197
Prostitutes	under 16 . .		1,647	1,647
„	over 16 . .		27,113	27,113
Suspected persons	under 16 . .	3,912	1,512	5,424
„	over 16 . .	28,028	5,774	33,802
Vagrants and tramps	under 16 . .	3,265	1,942	5,207
„	over 16 . .	11,390	5,962	17,352
		81,669	53,253	134,922

These are at large, and the numbers in prison on September 1858 were —in county and borough prisons, 15,774, of whom 11,742 were males, and 4032 females; 7628 in government convict prisons, of whom 6556 were males, and 1072 females; and 2022 in Reformatories, of whom, 1690 were males, and 332 females; making a total of 160,346 for the criminal classes. The distribution of criminal classes varies considerably; in the metropolis they form 1 in 187 of the population; in the pleasure-towns, such as Brighton, Bath,and others, they are 1 in 97; in towns depending upon agricultural districts, Ipswich, Reading, Lincoln, and others, they are 1 in 78; at the commercial ports, 1 in 93⅓; in the seats of the cotton and linen manufactures, 1 in 154⅓; in the seats of the woollen and worsted manufactures, 1 in 175½; in the seats of the small and mixed textile manufactures, Norwich, Macclesfield, Coventry, &c., 1 in 113; and in the seats of the hardware manufacture, 1 in 48. The agricultural districts vary less: it is 1 in 115 in the eastern; 1 in 104⅓ in the south and south-western, and 1 in 103⅓ in the midland. These numbers are so far satisfactory that, though large, they are not so large as have often been estimated. In 1801, for instance, Mr. Colquhoun ('Police of the Metropolis'), then stated the number of prostitutes at 50,000; a number much exceeding the whole number now in England and Wales. During the year, the police had information of 57,868 offences against the criminal laws; and 30,458 persons were apprehended, of whom 22,455 were males, and 8003 females; of the total, 11,789 were discharged, 191 discharged on bail, &c.; 1330 bailed to appear at trial, 82 committed for want of sureties; and 17,066 committed for trial. The number of persons tried was 17,855, of whom 4576 were acquitted or not prosecuted, and 33 were found to be insane. Of the convictions, 1393 were for offences against the person, of whom 38 were sentenced to death and 11 executed; 115 to various periods of penal servitude; 1166 to various periods of imprisonment with whipping, fines, &c.; and 74 to be whipped and discharged; for offences against property with violence, 1442 persons were convicted; of whom 15 were sentenced to death; 528 to various periods of penal servitude; 897 to various terms of imprisonment with whipping, &c.; and 2 to be whipped and discharged; for offences against property without violence, 9074 persons were convicted, of whom 1295 were sentenced to various terms of penal servitude; 759 to various terms of imprisonment, &c.; and 20 to be whipped and discharged; for malicious offences against property, 74 persons were convicted, of whom 40 were sentenced to various terms of penal servitude, and 30 to periods of imprisonment, &c.: for forgery and offences against the currency, 793 persons were convicted, of whom 131 were sentenced to periods of penal servitude, and 662 to various periods of imprisonment; for offences not included in the above classes, 470 persons were convicted, of whom 21 were sentenced to periods of penal servitude, 317 to various periods of imprisonment, &c.; and 132 to be whipped, fined, and discharged.

For minor offences the number of persons proceeded against summarily was 404,034, of whom 143,744 were discharged on examination by the justices, and 260,290 convicted, of whom 216,120 were males, and 44,170 females, of these, 65,261 suffered short periods of imprisonment, only 73 being above six months, and 20,968 being for fourteen days or less; 160,636 were fined; 10,360 were ordered to find sureties, 3781 were delivered over to the army or navy, 502 were whipped, and 19,750 otherwise punished. The offences for which convictions were obtained were, being drunk and disorderly, 51,861 persons, of whom 42,890 were males, and 8971 females; assaults of various kinds, 49,873 persons, of whom 40,893 were males, and 8980 females; trifling thefts and attempts to steal, 21,698, of whom 16,241 were males, and 5457 females; offenders under the Vagrant Act, 18,630, of whom 9798 were males, and 8832 females; for offences under the Police Act, the Hackney-carriage Act, local acts, Licensed Victuallers' and Beersellers' Acts, the game laws, and offences relating to servants, apprentices, &c. contribute the remainder. Of the total number of charges the report states that 54,149 were against suspicious characters, 153,576 of persons of previous good characters, 138,388 of persons whose characters were unknown, 17,683 against habitual drunkards, and 21,473 against habitual tramps.

Prisons.—In 1858 the total number of persons committed to them was 139,457, of whom 105,175 were males, and 34,282 females; a number not varying greatly from the average, but remarkable for the continued increase of commitments under the County Court Act, forming nearly 12 per cent. of the whole; but though these are punishments, being usually for what is termed contempt of court, that is, non-appearance or non payment of debt, they are scarcely to be considered criminal. There were committed for trial at assizes and sessions 18,904 persons, on summary convictions 83,128, for want of sureties 3678, on remand and discharged 12,519, for debt and on civil process 16,620, of whom 976 were women, and 4675 men, under the Mutiny Act, for desertion, &c. Of re-committals there were 41,580, of these 2131 males and 875 females had been committed above ten times, 754 males and 559 females had been committed from seven to ten times, and 13,574 males and 4694 females were committed for the first time. Of the total number 1553 were under 12 years of age, 8776 were between 12 and 16, the great mass were between 16 and 40, numbering 86,845; there were 12,088 between 40 and 50, 5297 between 50 and 60, only 2798 above 60, and 805 whose ages were not ascertained. Of the offenders 93,169 were English, 2867 Welsh, 2282 Scotch, 15,887 Irish, 567 colonial or East Indians, 1927 foreigners, and 1463 not known. Of the whole, 397 had received superior instruction, 6818 could read and write well, 68,227 could read and write imperfectly, 41,826 could neither read nor write, and 899 not ascertained. The total expense of prisons and prisoners for the year was 560,012*l.*, of which 151,267*l.* were for the maintenance of prisoners, the remainder of the nature of fixed charges for the buildings, management, &c. The whole sum gives an average cost for each prisoner of 29*l.* 16*s.* 8*d.*, apportioned thus:—for buildings and fittings, 11*l.* 11*s.* 8*d.*; officers and attendants, 10*l.* 3*s.* 11*d.*; prisoners diet, clothing, &c., 8*l.* 1*s.* 1*d.* The profits on the labour of prisoners had been 23,194*l.*, made up to 29,727*l.* by other small receipts, derived from prisoners; the local rates and funds produced 420,619*l.*, and 109,666*l.* were defrayed from the public revenue, the chief part as proportion of the charge on convicted prisoners. The convict prisons are now ten, the hulks have been altogether superseded, and transportation has in a great measure ceased. The number of convicts undergoing punishment at the commencement of the year was 7748, of whom 6795 were males and 953 females; during the year, 3171 males and 373 females were added, and 3410 males and 254 females were disposed of as follows:—1390 males were removed to Western Australia, Bermuda, and Gibraltar; 6 males sent to county gaols or reformatories, 12 males and 5 females transferred to lunatic asylums, 1557 males and 212 females discharged on termination of sentence, 303 males and 9 females with tickets of leave, 17 males and 4 females on commutation of sentence, 26 males and 10 females pardoned, 96 males and 14 females died, and 3 males escaped. At the end of the year there remained in the various prisons 6556 males and 1072 females. The cost of these convict prisons had been 262,473*l.*, the value of convict labour had been 7762*l.*, and the net yearly cost of each prisoner had been 31*l.* 14*s.* 10*d.* The criminal lunatics under confinement on Sept. 29, 1858, numbered 686; of whom 530 were males and 156 females. The total cost of police prosecutions in 1857, county and borough prisons, convict prisons, reformatories, and criminal lunatics, was 2,381,054*l.*, of which 1,590,850*l.* were defrayed from local funds, and 790,204*l.* by the government.

Crime in Ireland.—In 1858, the total number of persons committed or held to bail was 6308, a smaller number by 902 than in 1857. The convictions were 3350, there were 18 found insane, 1327 were found not guilty on trial, no bills were found against 971, no prosecutions were instituted against 492, and 150 were bailed and not tried. Of the committals, 4708 were males, and 1600 females. Of the number convicted, 895 were for offences against the person; 191 for offences against property, committed with violence; 1485 for offences against property, without violence; 31 for malicious offences against property; 25 for forgery and offences against the currency; and 723 for other offences not included in the foregoing classes, chiefly breaches of the peace. Of the convicted, 5 were sentenced to death for murder, and 4 were executed; 340 were sentenced to penal servitude for various periods; 2374 to various terms of imprisonment, 488 to be whipped, fined or discharged, and 140 of whom the sentence was respited, or who were pardoned. Of the convictions there were 1356 males, and 845 females, who could neither read nor write; 302 of both sexes were under sixteen, 1143 were under twenty-one, 2041 were between twenty-one and thirty, 1241 between thirty and sixty, 84 were above sixty, and of 1497 the age could not be ascertained. The number of prisoners in all the jails of Ireland was 2844 on January 1, 1859, a decrease of 421 from 1857. The total number of persons passing through prison in the year had been 33,999, of whom 28,501 were convicted either at assizes or quarter-sessions. At the sessions there were convicted and committed to prison 764 deserters, 1440 persons under the Vagrant Act, and 7873 for drunkenness, more than double the number committed in 1857.

Crime in Scotland.—In 1858 the total number of offenders committed for trial or held to bail was 3782, of whom 2718 were males, and 1064 females. Of these, 3167 were tried (615 having been discharged, found insane, or outlawed for non-appearance), and 2891 were convicted. Of the convictions, 1171 were for offences against the person, 440 for offences against property, committed with violence, 1734 for offences against property without violence, 93 for malicious offences against property, 91 for forgery and offences against the currency, and 253 for other miscellaneous offences. Of the total, 515 males and 294 females could neither read nor write, 1566 males and 670 females could read and write imperfectly, 529 males and 91 females could read and write well, and 80 males and 3 females had had a superior education. Of the punishments, none were sentenced to death, 289 were sentenced to penal servitude for various periods, the greater number for four years; 370 to imprisonment for periods between two years and more than six months, 1816 for various periods between six months and less than one month, 6 to be detained in reformatory schools, and 348 to be whipped, fined, or discharged on sureties. Of the number committed, 93 were under twelve, 315 between twelve and sixteen, and 52 were above sixty years of age. The number of prisoners in all the prisons of Scotland on December 31, 1858, was 2114 for criminal offences, and 72 on civil cases, of whom 1189 were males, and 997 females; the number of commitments in the year had been 17,922.

CRIMINAL CONVERSATION. [ADULTERY.]

CRIMINAL LAW. [LAW, CRIMINAL.]

CROCKET, an ornament of very frequent use in Gothic architecture. It consists of leaves, leafy buds, or flowers, growing out of the angular sides of pinnacles, spires, canopies, and the label moulding of windows and doors, and sometimes, though less frequently, in other places the only exception to their occasional use in Gothic work of some period or place seeming to be upon horizontal features. Figures of animals occasionally occur as crockets. There are no examples of crockets in the Norman or round arched style. In the first pointed, or Early English style they are meagre, as in Lincoln cathedral, but afterwards they become fuller, and more natural in their imitation. The latest examples, however, are larger, and have not so much the appearance of nature.

CROCONIC ACID. [RHODIZONIC ACID.]

CROCUS OF ANTIMONY. [**ANTIMONY,** ***compounds with sulphur.***]

CROCUS SATI'VUS—***Medical properties of.*** The saffron crocus is a native of Asia Minor, but is extensively cultivated in the more southern countries of Europe. That which is obtained in England, chiefly from Suffolk, is from the *Crocus autumnalis*, and is scarcely now to be met with, being nearly supplanted by the saffron imported from Spain. The officinal part is the stigmata of the flower, with a small part of the style attached. The part of the style receives the name of föminelle, and the less of this there is, the finer is the saffron. The stigma consists of three narrow club-shaped, somewhat petaloid portions, about one or two inches in length, of a brown or orange-yellow colour, with an aromatic, pleasant, but somewhat stupifying odour, and bitterish aromatic taste. The plant flowers in September and October, and once a day (some say twice) the stigmata are carefully plucked out of the open flowers, and dried on paper or sieves, either in the sun, in a room, or by kilns, if the weather be unfavourable for drying in the sun. The attention necessary for procuring it in perfection may be estimated from the circumstance that nearly 40,000 flowers are required to yield one pound of saffron. The statement that 107,520 or still more 203,920 flowers are required is a gross exaggeration. The good saffron occurs only in the state called *hay*; that which is termed cake saffron is entirely composed of the flowers of a compound plant called *Carthamus tinctorius*, or safflower. Other sophistications are said to be practised, but they are of rare occurrence, except oiling old saffron, to give it the appearance of fresh. Portions of smoked flesh are easily detected by not yielding colour like saffron. The chemical analysis by chemists agrees as to constituents, but differs as to the respective quantities, a difference arising from the quality of the specimens examined.

	Vogel and Bouillon Legrange.	Aschoff.
Volatile oil	7·5	1·4
Wax	0·5	4·0
Polychroite	65·0	52·0
Gum	6·5	10·4
Soluble albumen	0·5	—
Woody fibre	10·0	19·0
Water	10·0	10·0
Balsamic matter, soluble in ether and alcohol	—	2·0
	100·0	98·8

The volatile oil is yellow, and heavier than water, and possesses a bitter, acrid, burning taste, and is partially soluble in water. By keeping it undergoes some change, for it becomes white, and is then lighter than water. To it is chiefly owing the medicinal properties of saffron, while the colour seems owing to the *polychroite*, which seems to be a combination of a volatile oil and a red bitter substance.

Saffron formerly enjoyed a high repute, both as a perfume, and as a nervine, stomachic, and narcotic drug. That the odour has powerfully affected some very susceptible individuals is undeniable; but so little regard is now paid to it, that it is employed chiefly as a colouring ingredient, or adjunct to other more powerful agents. It is still a popular remedy during the eruptive stage of exanthematous diseases, a remnant of the old doctrine of colours; and to the same notion is to be referred the practice of giving it to canary birds when moulting, a practice reprobated by Bechstein, who judiciously recommends iron to be put into the water at these times, such as a rusty nail. (Bechstein, On 'Cage Birds,' p. 223.)

The stigmata of the *Crocus vernus* have a colouring principle which is imparted very readily to alcohol, less so to water or oil. But as these can be procured at a much cheaper rate than those of *C. sativus*, they might be used where colour alone is required.

CROMLECH. Certain primeval remains, consisting of three or more rude stones set upright in the earth, and supporting one large horizontal stone so as to bear a general resemblance to a table, have long been known in this country as cromlechs. The first application of the name does not appear to be known, but if its meaning be as stated by Dr. Pughe, "an inclined or flat stone," it would seem to be merely a convenient popular designation. Worsaae and some recent antiquaries have extended the word so as to make it synonymous with the German Steingräber, and Hünengräber, stone graves and giants' graves; but here it will be used in its more confined and more usual sense.

Cromlechs are met with in various parts of England, Ireland, Scotland, and Wales, and the Channel Islands; in Brittany and other parts of France (where they are known as *Dolmen*); in Germany, Denmark, Spain, and elsewhere in Europe; in North and South America, and even in various parts of Hindustan (Capt. Meadows Taylor, 'Cromlechs, Cairns, and other Scytho-Druidic Remains in the principality of Sorapur;' and Hooker's 'Himalayan Journals,' ii. p. 320, &c.) They have consequently formed a fertile subject for the speculations of antiquaries and local historians. By many of our earlier antiquarian writers they were regarded as closely connected with the rites of Druidic worship—whence their common name of *druidical altars*. The top or cap-stone, or *bowing-stone* as it was sometimes called, was considered to have been placed in a horizontal position in order to receive the human victim; a slight inclination being given to the stone for the purpose of letting the blood run off. A single stone of large size occasionally found near the cromlech was supposed to have served as a pedestal for some deity. These opinions are pretty well exploded now. It is seen that the cap-stones have almost invariably the flat side turned downwards, and are indeed in all respects as unfitted for the reception of sacrificial victims as they well could be. On the other hand, wherever they have not been disturbed human remains are found in connection with them. Extended investigation has shown that among races in an early stage of civilisation it was a very wide-spread practice to protect the remains of a person of consequence with a massive stone covering. Cromlechs are now, in short, admitted by all archæological inquirers to have been places of sepulture. Originally, they were covered over with earth, and the circle of small stones by which they are still in many instances surrounded was probably the boundary of the enclosure, and defined the base of the tumulus. Much light has been thrown on the purport of cromlechs, and the modes of interment adopted in connection with them, by Mr. Lukis, who explored a large number of these monuments in Guernsey, which had fortunately been previously unopened. He found on removing the superincumbent earth and sand outside the inner chamber, or cromlech proper, not only human bones, but bones of the horse, the ox, and the boar; stones used for grinding and pounding, stone quoits, hammers, chisels, arrow-heads, &c., as well as rude pottery; and within the chamber, burnt human remains, and jars of various sizes containing limpet shells, &c., which he with great probability supposes were intended as food and offerings to the manes of the deceased. "The burnt human bones," he says, "appeared in distinct heaps, and the jars in contact had partaken of the colour of them. The very perfect calcination which had been adopted, made it difficult to conceive what kind of process had been used. Little or no charcoal was observed; the teeth were of a fine jet black; and the bones of the jaws grayish white; and, in some instances tinged with turquoise green colour." In the cromlech opened by him at L'Ancresse, in the northern part of Guernsey, Mr. Lukis found forty urns, varying from four to eighteen inches in height, but from the fragments of pottery remaining he arrived at the conclusion, that "not fewer than one hundred varieties of vessels must have been deposited from time to time during the primeval period." But he found in some cromlechs bodies interred which had not been subjected to cremation. Thus in one of the most extensive of the sepulchral chambers opened by him, called the Cromlech Du Tus, Mr. Lukis discovered on removing the cap-stone of the cromlech, two entire skeletons placed side by side in a kneeling position, the face of one being directed towards the north, and that of the other towards the south. ('Archæological Journal,' vol. i., and 'Journal of the Archæological Association.')

One of the largest of these remains in Great Britain is a double cromlech at Plas Newydd, Anglesey. [Anglesey, in Geog. Div.] The cap-stone of the larger of the two cromlechs is 12 feet long, 10 feet broad, and 4 feet thick, and is supported by four tall stones. There are, or were a few years back, no fewer than twenty-six other cromlechs in the Isle of Anglesey. One of the best known cromlechs in the southern part of England is that called Kit's Coty House, which stands near the road between Maidstone and Rochester, Kent. [Aylesford, in Geog. Div.] This, which resembles in character the Cromlech Du Tus, in which Mr. Lukis found the two kneeling skeletons, is formed by four upright stones, three of which standing on end and inclining slightly inwards, support the fourth, or cap-stone. This last is a huge block, 12 feet long, 9 feet wide, and 2 feet thick; while two of the upright stones are 8 feet high, 7 feet wide, and 2 feet thick. Another very noted cromlech consisting of several stones is that known as Wayland Smith's Cave, at Ashbury in Berkshire [Berkshire, in Geog. Div.], but it is now in a very imperfect state, many of the stones having been broken and carried away for building a neighbouring barn.

CROPS. [Emblements.]

CROPS, ROTATION OF. [Arable Land.]

CROSIER, or CROZIER, from *Crocia*, in the Latin of the middle age, a pastoral staff or crook, formerly used by bishops and abbots. Several writers have supposed that it was derived from the *lituus*, or augural staff of the Romans: but they are mistaken. It was evidently copied from the well-known and common staff which shepherds, even to this day, make use of to catch hold of the hinder leg of their sheep in order to take them; and it has reference to the pastoral office of the bishops and clergy, according to the words of our Saviour, "I am the good shepherd," and to the common name of the clergy, pastors or shepherds.

These pastoral staffs were sometimes barely curled, and at others very richly ornamented; a few instances occur in which the upper part finishes in the form of a mace. The Sieur de Moteon, in his 'Voyages Liturgiques de France,' 8vo, Par. 1718, p. 272, says, many of the early crosiers were not curved. The abbot's staff was usually of a simpler form than that of the bishop. One of the earliest abbatical staffs, the form of which can be seen in England, is probably that represented on the tomb of abbot Vitalis, in the cloister of Westminster Abbey, who died in 1082. Some of the episcopal crosiers appear to have been among the most exquisite examples of the 13th and 14th century Italian goldsmiths' and enamel work; some of the French crosiers of the same date are also extremely rich and of admirable workmanship. (Labarte, Du Sommerard, De Caumont, Waring, &c.) The most splendid English episcopal crosier remaining is that of William of Wykeham, of silver gilt, richly enamelled, which is exhibited to visitors in the chapel of New College, Oxford, to the society of which the bishop himself bequeathed it in 1404. (See Lowth's 'Life of Wykeham,' 3rd edit. 8vo, Oxf. 1777, p. 263, where it is engraved.) Another very fine cross, beautifully ornamented with nielli, is that of Bishop Fox (died 1528), preserved at Corpus Christi College, Oxford. A crosier of oak was found on opening the tomb of Bishop Fox at Winchester. Crosiers of wood were in ancient times usually buried with bishops and abbots in their coffins. One, of red wood, the top carved into the rude form of a ram's head, was found many years ago, upon opening the coffin of bishop Grosteste at Lincoln, who died in 1253. It lay across the body from the right shoulder to the left foot. At the bottom of the neck of this staff, upon a brass plate, was this inscription: "Per baculi formam Prelati discito normam." (Gough, 'Sepulchr. Mon.' vol. i. p. 47.)

According to Labarte it is an error of modern writers to apply the term crosier "to the crook-shaped pastoral staff of a bishop; the crosier, strictly so called, is the cross on a staff borne by an archbishop." ('Arts of the Middle Ages,' p. 430, trans.) But whatever may be the "strict" use of the term in the Romish church, crosier is the received term among English archæologists for the episcopal crook. The crosier in the sense used by Labarte, or as we should say the cross, is employed by the Romish hierarchy as a mark of distinction. Thus the pope alone is entitled to have a cross with three transverse beams carried before him; cardinals and archbishops have the double cross; while bishops have a cross of the ordinary form, or with a single beam. (Didron, 'Iconographie Chrétienne.')

CROSS. Various religious edifices called crosses, from their being surmounted with this emblem of Christianity, have been erected in England and on the Continent. Of these, the most remarkable in England are the memorial crosses erected on the places where the body of Eleanor, queen of Edward I., rested each night on its way for interment in London. Three of these still remain, at Geddington, Northampton, and Waltham Cross, near London. The last, which is the most elegant, consists of four stories. It is hexagonal on the ground plan, and beautifully enriched; the story immediately above this is supported by buttresses, and formed into niches, in which are three figures of the queen. The core at the back of the figures is carried up beyond the niches, and has been restored with a battlement and a cross sustained on a crocketted spire. Market-crosses were formerly very common in England. They are often designed with niches and vaulted, thus forming an open chamber, as at Salisbury and Chichester. Other crosses of this kind remain at Malmsbury, Glastonbury, and elsewhere. Winchester Cross, which is one of the most perfect of the crosses erected for religious purposes, is of much later date than those erected in memory of Queen Eleanor. Near Ely, on the road to Downham Market, there is a singular cross, consisting of a long slender stone shaft, on the top of which there are richly carved niches projecting beyond the sides of the shaft. Pillar crosses were often erected in churchyards, as well as by the way-side or meeting of four roads; and many of these still remain, though usually in a mutilated condition. Perfect churchyard crosses, however, exist at Great Grimsby, Higham Ferrers, &c.

Churches are usually built in the form of a cross. [Church.] The largest of these constructed crosses are those of St. Peter's at Rome and St. Paul's, London. In the Western Church, what is called the Latin cross has mostly been employed; whilst in the Eastern Church the Greek cross has been commonly used: the difference in the form being that, in the Greek cross the four arms are of equal length, while in the Latin the lower arm (the nave in churches) is longer than the rest. What is called the Maltese cross is merely the Greek cross with an ornamental expansion of the extremities of the arms. On the symbolism of the different forms of the crosses used in Roman Catholic ceremonials, and seen in pictures, sculptures, &c., see Didron, 'Iconographie Chrétienne.'

Churches and ecclesiastical buildings almost always had crosses fixed on their gable ends. These crosses varied considerably in form and style of ornament in the different periods of Gothic architecture; many of them are of great elegance; but crosses having being condemned as superstitious by the parliamentary visitors of the Commonwealth period, large numbers were destroyed or mutilated. A large cross, or crucifix, called a rood, was, prior to the Reformation, placed over the chancel in most parish churches, and in all cathedrals, upon a beam or gallery, called the rood-beam or rood-loft. The cross upon the altar was usually a crucifix; that is, had a figure of the Saviour represented hanging upon it. A cross was very commonly the principal figure carved upon monumental brasses [Brasses], and indeed upon monuments generally.

By European navigators, the planting of a cross was used to indicate that possession was taken of the country for the nation by whom it had been discovered.

Crosses used for processional purposes were during the middle ages often made of great beauty and costliness. A very excellent specimen of a processional cross of the 14th century is engraved as a frontispiece to Paley's 'Gothic Architecture.'

In some of the Roman Catholic processions at Rome enormous crosses, constructed of wood and cardboard, are carried, balanced in a waistband round the body of a strong man.

CROSS, from the Latin 'Crux.' This cruel mode of punishment appears to have been in use from the earliest recorded periods of history. It was possibly the invention of some barbarous tribe to prevent the escape of a captive by fastening him to a tree, or used to inflict death on an enemy by leaving him to expire of want, or a prey to birds and beasts.

Crosses, whatever was the original form, were, in course of time, made of two pieces of wood. These crosses have been divided by antiquaries into three kinds. The crux decussata, or cross divided like the letter X, and usually called St. Andrew's cross; the crux commissa, or joined cross, consisting of an upright piece of timber with a transverse piece on the extreme top at right angles with the first, like the letter T; and the crux immissa, or let-in cross, in which the transverse piece of timber is let into the upright, but placed somewhat below the top of the upright in this form ✝. This is the cross on which Christ is usually represented to have suffered, and though there may not be any absolute authority for ascertaining the precise form of the cross used on that occasion, yet apart from the fact of the early Christian writers having without exception referred only to this form, the circumstance of an inscription having been placed over his head would render the conjecture probable.

Amongst the Carthaginians, persons of all conditions, even commanders of armies, were subjected to it, but amongst the Romans it was considered as the punishment of slaves, and inflicted on that class only. With respect to the Jews, it seems doubtful whether crucifixion, as we understand it, was a mode of punishment used by them in ancient times. The putting the sons of Saul to death by the Gibeonites has been adduced as furnishing evidence that crucifixion was practised by them (2 Sam. xxi.); but the practice does not seem to warrant the conclusion. It is however to be observed that "hanging on a tree" is used in Scripture to describe crucifixion. (Acts x. 38.)

Previous to crucifixion the sufferer was scourged. He was also forced to carry his own cross; and this (amongst the Romans at least) probably arose from the disgust and horror with which this instrument of punishment was viewed and considered by that people, and their disinclination even to touch it. (Cicero 'in Verrem.') The criminal was accordingly condemned to bear his own instrument of torture. Previous to the infliction of the punishment, the sufferer was stripped naked, and it is probable that he was laid down on the cross for the purpose of having the nails driven in his hands and feet, or being fastened with ropes, which was sometimes the case. The cross was then elevated. Afterwards the legs were broken, wounds inflicted with a spear, or other sharp instrument, to hasten death, but this was not invariably done. As death, in many cases, did not ensue for a length of time, guards were placed to prevent the relatives or friends from giving the sufferers relief, taking them away whilst alive, or removing their bodies when dead. The punishment of the cross was abolished in the Roman empire by Constantine, who substituted hanging.

The representations of crucifixions by painters are calculated to give very erroneous notions both of the cross itself and the mode of punishment. It is not probable that the crosses actually used were so lofty or so large and massive as those which we see in pictures. Instruments of such dimensions would be perfectly unnecessary for the purpose. When we read in Josephus of hundreds of Jews being crucified by Vespasian and Titus in a day, we cannot suppose that so great a quantity of timber would be used on those occasions. The circumstance of the sufferer carrying his own cross weighs against the probability of its being of the size which these representations give it. It is not unusual in paintings to represent crucifixion as taking place after the cross is elevated, and the executioner is represented standing on a high ladder, and driving a nail into the hand of the crucified person. It seems much more likely that the sufferer was nailed to the cross before it was raised and fixed in the ground. "Pone crucem servo," "Put the cross to the slave," is the expression used by Juvenal. Crucifixion sometimes took place with the head downwards, and St. Peter is said to have suffered death in this way.

Death by the cross, in a strong and healthy person, must necessarily have been tedious and lingering, and instances have occurred of persons who, after remaining some time on the cross, were taken down, and survived. When the crucified person was only attached to the cross by ropes, this seems by no means extraordinary; and even when it took place by nailing, neither the wounds themselves nor the quantity of blood lost would be sufficient in all cases to bring on speedy death. During the reign of Louis XV. several women (religious enthusiasts, called Convulsionnaires) voluntarily underwent crucifixion. Dr. Merand, an eye-witness at some of the meetings of these persons, relates that he was present at the crucifixion of two females, named Sister Rachel and Sister Felicité. They were laid down, fixed by nails five inches long driven firmly through both hands and feet into the wood of which the crosses were made. The crosses were then raised to a vertical position. In this manner they remained nailed, while other ceremonies of these fanatics proceeded. Sister Rachel, who had been first crucified, was then taken down: she lost very little blood. Sister Felicité was afterwards taken from her cross. Three small basins, called palettes, full of blood, flowed from her hands and feet. Their wounds were then dressed, and the meeting was terminated. Sister Felicité declared that it was the twenty-first time she had undergone crucifixion.

CROSS BILL. [Pleading.]

CROSS BOW. [Archery.]

CROSS REMAINDER. [Remainder.]

CROTALUM (*κρόταλον*), an ancient musical instrument, which, as appears from medals, was used by the Corybantes, or priests of Cybele. The crotalum differed from the sistrum, though the names are often confounded, and is by some supposed to have been of the castanet kind. ('Dict. de Trevoux.') Some consider it as a cymbal of small dimensions; and from the allusions to it by Virgil, Lucretius, and others, we are inclined to be of the latter opinion.

CROTCHET, in music, a character or note formed of a round head, and a stem descending from the left side of the upper part—

It is the fourth part of a semibreve, and in slow time (*largo*, for instance) its duration is about one second.

CROTON OIL. The seeds of the *Croton Tiglii* were formerly used as a drastive purgative medicine, under the name of grains of Tilly, or Molucca grains, or purging nuts, a term which occasionally leads to confounding them with physic nuts, the produce of the *Jatropha Curcas;* but at present the oil only is employed. The seeds are roasted, and then subjected to compression; the oil is therefore termed an expressed oil. It is of a honey-yellow or brownish colour, of moderate consistence, having an odour resembling the resin of jalap; the taste is at first slightly rancid, afterwards acrid, causing a feeling of burning in the throat, which lasts for several hours.

A portion of the oil is taken up by alcohol, and more by ether; it is however soluble in every proportion in fixed and volatile oils. It was supposed to contain a peculiar principle termed Tiglin; but this is now known to be a magnesian soap. It is often adulterated with olive or castor oil, which admixtures may be detected by the process suggested by Dr. Nimmo. An artificially prepared substitute, sometimes met with, is a mixture of the resin of jalap, Canada balsam, fixed oil, euphorbium, &c. (Horst.) The oil of the seeds of *Jatropha Curcas* (Linn.) is also sometimes mixed with the genuine oil. In the dose of one drop (when the pure oil is used) it produces considerable purgative effect, and may be very advantageously employed when difficulty of swallowing exists, since its application to the tongue is often sufficient to ensure the purgative action. Hence in cases of apoplexy, or paralysis of the throat, the desired effect may be obtained even when the patient is insensible. In the treatment of that form of inflammation of the brain termed hydrocephalus, even when effusion appears to have taken place, and torpor or paralysis exists, croton oil will often bring about the recovery of the sufferer. (See Abercombie on 'Diseases of the Brain, 1st edit., p. 157.) In cases of impending apoplexy croton oil is of incalculable value. It is likewise used, but sometimes very improperly, in cases of obstruction of the intestinal canal. It is however useful in aiding in the expulsion of the tape-worm, when proper anthelmintic medicines have been prescribed. The powerful impression which it makes on the intestinal canal renders it useful in some cases of dropsy. It is in most instances proper to combine it with castor oil, almond emulsion, or an alkali, to lessen its acrimony.

The seeds are employed in India, "and are used in the form of pills, commonly called *Jamalgota pills*. The natives usually separate the embryo, and combine the albumen of the seed with catechu or pepper." (Royle.) Where the embryo is not extracted before using, even one seed has proved fatal. As the embryo seems to possess the greatest acrimony and purgative power in the *Jatropha Curcas*, this is removed by the inhabitants (Europeans) of the East Indies, and one seed may then be eaten with comparative safety; but a seed not so treated is then offered to an inexperienced person, and, if eaten, followed in many instances by serious consequences,—a very *mauvaise plaisanterie*.

The oil diluted with five parts of olive oil, or seven of oil of turpentine, is occasionally employed as a liniment to bring out a pustular or vesicular eruption, and to act also as a rubefacient; but this also requires caution.

CROTONIC ACID. An unimportant oleaginous acid obtained from *croton oil*. Its vapour is irritating to the eyes, and the acid itself is poisonous. Its composition is unknown.

CROTONINE. A doubtful alkaloid, said to be found in the seeds of the *croton tiglium*.

CROUP, a specific inflammation of the air tubes, giving rise to a peculiar secretion, which concretes almost immediately it is formed, producing a false membrane, which lines the affected parts. It has been shown [CATARRH] that the mucous membrane which lines the air passages is subject to two different kinds of inflammation, each presenting distinctive characters. In one the inflammation produces a secretion which does not concrete, constituting all the varietes of bronchitis, catarrh, &c. In the other the inflammation produces a secretion which consolidates almost the moment it is formed, giving rise to the various phenomena which constitute the peculiar disease denominated croup.

That the inflammation which terminates in the formation of the secretion peculiar to croup is of a specific nature, is argued, first, because it uniformly terminates in the production of this peculiar secretion; and, secondly, because this secretion is obviously not dependent on the intensity of the inflammatory action, since the phenomena characteristic of inflammation are often less acute in croup than in catarrh. It has been conjectured that catarrh depends upon inflammation of the secreting follicles of the mucous membrane, and that croup depends upon inflammation of the capillary arteries of its tissue, a conjecture which is probably correct, though in the present state of our knowledge it must be regarded merely as a conjecture. As the inflammation, however, presents in the essential phenomena characters so different, it is convenient to distinguish the one from the other by distinct names, and accordingly the former is termed catarrhal, and the latter plastic inflammation.

The false membrane, the result of plastic or croupal inflammation, moulds itself to the part inflamed; it does not extend beyond the inflamed portion of the mucous membrane; it varies in thickness from half a line to a line; it is of a white or whity-brown colour; it has the consistence of boiled white of egg, and its firmness is always greatest where it is thickest. When it is raised from the mucous membrane, the latter is always found to be reddened and swollen, but rarely to the degree common in catarrh.

This morbid secretion is most commonly poured out on that portion of the windpipe which constitutes the larynx; hence in general the larynx forms the peculiar and proper seat of croup; but the site of this adventitious membrane is by no means confined to the larynx; it often extends above to the glottis and epiglottis, and below to the bronchial tubes. When, as happens in the great majority of cases, the adventitious membrane is confined to the larynx and epiglottis, it presents the characters just described; but when it extends into the bronchial tubes it becomes modified in its appearance. It is then generally "formed into a single cylinder, but occasionally into a series of tubes inclosed within each other in the closest contact, and forming altogether a solid body, of a thick and tolerably firm structure, and in the exact form of the tube from whence it has been abstracted. Upon making a transverse section of this polypiform substance, concentric laminæ are very apparent. It adheres but slightly to the mucous surface, and may easily after death be drawn out entire, presenting a complete mould of a large bronchial tube, with all its subdivisions, down to its minutest ramifications."

Though in the croup the deposition of the adventitious membrane is commonly confined to the larynx, yet other parts of the mucous membrane in the immediate neighbourhood of the larynx are sometimes the seat of plastic inflammation, terminating in the formation of a precisely analogous morbid secretion. Occasionally "small yellowish-grey spots appear upon the fauces, surrounded by the mucous membrane, highly and darkly reddened. These spots enlarge, coalesce, and form a continuous false membrane, of the colour and consistence of the buffy coat of the blood, lining the throat more or less completely. Sometimes it is seen to cover the posterior half of the tongue, so that its anterior part might be elevated by a probe in a membranous form; occasionally, though not often, it passes down the œsophagus even into the stomach, but much more frequently it extends into the lung, producing all the symptoms of croup. When plastic inflammation is seated in the fauces, it gives rise to a disease called Cynanche Maligna, or gangrenous sore throat, so named from the supposition that the spots on the fauces consist of gangrenous sloughs; but more careful observation has demonstrated that they consist of an adventitious membrane. Nevertheless, gangrene does occasionally, though very rarely, co-exist with the deposition of a fictitious membrane, that is, the false membrane is deposited over a gangrenous surface." [DIPTHERIA.]

The most striking and characteristic symptoms of croup of course depend on the consequences that result from the obstruction to the free passage of the air to the lungs, that is, impeded respiration and change of the voice. The respiration is impeded in proportion to the quantity of adventitious membrane that is formed, and the consequent degree in which the calibre of the air-tube is diminished; in proportion to which must of course be the diminution in the column of air admitted to the lung. The air-passage in the progress of the disease is often obstructed to such a degree as to produce a most painful feeling of suffocation, attended with all the signs that denote the imminent danger of suffocation, and death is constantly occasioned by the narrowing of the air-tube to such an extent as actually to produce suffocation. In milder cases, when not impeded to this extreme degree, the respiration is still always difficult, anxious, and distressing. The edges of the circumference of the inferior extremity of the adventitious deposit being loose, mucous, and soft, frequently adhere to each other, so as to close up the tube, and require a strong effort of inspiration to overcome the temporary obstruction. "I have seen," says Dr. Davies, "a slight film of pseudo-membrane traversing the upper part of the larynx suffocate an infant almost instantly. The dyspnœa becomes always great when the concretion separates, and if it be not quickly expectorated, often destroys the patient immediately."

Owing to the diseased condition of the air-tubes, the acts of respiration and of coughing produce peculiar sounds. The inspiration is sonorous and ringing, as if the sound were formed and resounded in a brazen tube. Sometimes it is dry and hissing, resembling the sound produced by a piston forced through a dry pump, or by a crowing noise similar to that emitted by a chicken in the pip. The croupal cough is a peculiar, loud, clangous, ringing sound, which has caused it to be almost universally compared to the crowing of a cock. The voice partakes of the same character, being shrill and hoarse.

The fever excited in the system by this local inflammation is commonly acute and intense. The skin is burning hot; the face flushed, sometimes covered with perspiration; the eyes prominent, injected, or watery; the carotid arteries throb powerfully; the jugular veins are tumid, and the pulse at the wrist is frequent, hard, and wiry. Sometimes, on the contrary, the febrile symptoms are of a low or asthenic character; the skin cool, and of a dirty pallid colour; the pulse frequent, but exceedingly feeble; the breath fœtid, and the general prostration extreme.

As the disease advances, the restlessness and anxiety of the patient increase; the hand is constantly applied to the throat, which is often slightly tumified externally, and sometimes painful to the touch; the respiration becomes more and more difficult, the cough convulsive and exhausting, the countenance bloated, and the cheeks and lips either livid or exceedingly pale. In this stage the pulse becomes small, weak, and irregular, the eyes sunk, the skin cold and clammy, the voice lost, or capable only of a whisper; the head is constantly tossed back; the throat often seized as if to remove an obstacle to respiration; violent efforts are made to expand the lungs, and death at length puts an end to a state of intense suffering, either by convulsive suffocation, or by the subsidence of the restlessness and violence into a state of profound lethargy and stupor.

Croup, as has been stated, is almost peculiar to infants. It may occur at any period from the second month after birth to puberty; and the younger a child is, after it is weaned, the more liable it is to the disease. It is most apt to occur in the sanguineous temperament and the full habit. It often seizes a child not perfectly recovered from a previous illness, and is liable to a recurrence at distant intervals on exposure to causes which ordinarily produce only common catarrh. Yet it occasionally occurs in the adult, generally as a consequence of its extension from the fauces to the larynx. It is chiefly prevalent in the neighbourhood of large bodies of water, running or stagnant, salt or fresh, and especially among the ragged and half-starved children of the poor, who live on the sea-coast, or near the banks of rivers or canals. But it also occasionally prevails in other situations as an epidemic, especially during the continuance of north or easterly winds, after heavy and long-continued falls of rain.

There is perhaps no disease to which the human body is subject the progress of which is so frightfully rapid. In a few hours after the attack, the morbid secretion is often formed to such an extent, as to prove inevitably mortal; yet the inflammation of which it is the result might have been checked by immediate, vigorous, and judicious treatment. It is therefore of the last importance that those who have the care of infants and young children should be familiar with the first signs of the approach of this dreadful malady. Of these a graphic description has been given by Dr. Cheyne, who had abundant experience of the disease in situations in which it is but too prevalent. After having pointed out the importance of attending to the first appearance of hoarseness, which in very young children does not usually attend common catarrh, and consequently, when observed in a child living in a district which generates croup, this symptom is always much more deserving of attention, especially if accompanied with a rough cough, than it would be after puberty, this excellent physician says,—

"In the approach of an attack of croup, which almost always takes place in the evening probably of a day during which the child has been exposed to the weather, and often after catarrhal symptoms have existed for several days, he may be observed to be excited; in variable spirits; more ready than usual to laugh or to cry; a little flushed, occasionally coughing; the sound of the cough being rough, like that which attends the catarrhal stage of the measles. More generally however the patient has been for some time in bed and asleep before the nature of the disease with which he is threatened is apparent; then, perhaps without awaking, he gives a very unusual cough, well known to any one who has witnessed an attack of the croup; it rings as if the child had coughed through a brazen trumpet; it is truly a *tussis clangosa*; it penetrates the walls and floor of the apartment, and startles the experienced mother—'Oh, I am afraid our child is taking the croup!' She runs to the nursery, finds her child sleeping softly, and hopes she may be mistaken. But remaining to tend him, before long the ringing cough, a single cough, is repeated again and again: the patient is roused, and then a new symptom is remarked; the sound of his voice is changed; puling, and as if the throat were swelled, it corresponds with the cough: the cough is succeeded by a sonorous inspiration, not unlike the kink in pertussis—a crowing noise, not so shrill, but similar to the sound emitted by a chicken in the pip (which in some parts of Scotland is called the roup, hence probably the word croup); the breathing, hitherto inaudible and natural, now becomes audible, and a little slower than common, as if the breath were forced through a narrow tube; and this is more remarkable as the disease advances. A blush of inflammation may sometimes be detected on the fauces, and in some rare instances a slight degree of swelling round the larynx, and the child complains of uneasiness in his throat, and says he is choking. The ringing cough, followed by crowing inspiration, the breathing as if the air were drawn into the lungs by a piston, the flushed face, the tearful and blood-shot eye; quick, hard, and incompressible pulse; hot dry skin; thirst, and high-coloured urine—form a combination of symptoms which indicate the complete establishment of the disease. Sometimes the symptoms enumerated subside about midnight, even in the absence of medical treatment; perhaps to return in the course of the following evening. From seven or eight o'clock till midnight this complaint is always at its height; but in general, unless the patient be treated with promptitude and judgment, the disease may be expected to terminate fatally; a new order of symptoms, the second stage of croup, as it is called, taking place in the course of the next day."

If the diet of the child be changed from its ordinary food to that of the simplest and blandest kind, as gruel or arrow-root, the moment the hoarse cough and rough voice are perceived; if it be immediately placed and kept in bed in an equable and moderately warm temperature, and one grain or two grains of the powder of ipecacuanha be given every hour, or every alternate hour, all the symptoms may subside without any further remedies, and the threatened attack be effectually prevented; but if with this hoarse cough and rough voice the child be allowed its ordinary diet, and be exposed as usual to the open air, the attack will hasten on in the mode described until the disease is fully established; and then any treatment that may be employed, to be of the least avail, must be most energetic. The prompt employment of the most powerful remedies is indispensable; yet they must be administered with cautious and judicious boldness. It is a disease in which the inflammation, which it is the great object of medical treatment to subdue, is not so much of a violent as of a peculiar character, and this renders it necessary that the practitioner should be guarded in the administration of some of the more powerful remedies to which he must resort, and especially in the employment of blood-letting. When the fever is intense, the skin hot, the pulse full and hard, and the patient plethoric, bleeding must indeed be employed, and carried as far as the strength will admit; but experience has amply shown that in this disease the strength will not admit of its being carried as far as is safe and even necessary in diseases purely inflammatory. Bleeding, either by the lancet or by leeches, which latter should never be applied to the throat itself, but to its immediate neighbourhood, is a most powerful auxiliary; but it is not *the* remedy to be relied on. *That* is mercury, which should be given instantly and efficiently, that is, in doses of from one to three grains of calomel every hour, or every two hours, until the mouth be affected, the breath fœtid, or the patient relieved. If the calomel irritate the bowels, the *hydrargyrum cum creta* may be substituted, or a free inunction of the mercurial ointment, which latter may be conjoined with the calomel, or the mercury and chalk powder. Many practitioners prefer the full employment of tartar emetic to the mercurial plan of treatment. All agree that blisters are useful auxiliaries, applied at the bottom of the sternum, or between the shoulders, but never at the throat. The vomiting produced by the tartar emetic sometimes powerfully promotes the expulsion of the adventitious membrane. There are other remedies of minor importance, the judicious employment of which may assist in putting a stop to the progress of this most formidable malady. The use or abuse of these cannot be discussed here; but what has been stated may excite the attention of the mother, and guide her to the choice of efficient remedies in the first hour or two of the attack, during which it may not be always possible to obtain medical aid.

CROWN, the ornament of the head which denotes imperial or royal dignity, from the Latin *corona*. The radiated appears to be the earliest form of the royal crown with which we are acquainted. It appears upon the heads of the figures which are represented upon the Persian darics: radiated crowns also occur on the coins of Antiochus IV. of Syria, and of his successors; on many of those of the Greek cities; and on those of Augustus and other emperors down to the very destruction of the Roman empire. The fillet, and the laurel wreath, were also used as crowns in very remote times: the fillet was the most universal of all. In Constantine's time the fillet of pearls came into use; which the latter Byzantine emperors turned into a kind of coronet. Focas, as he is called upon his coins (not Phocas), has a plain low crown. Later emperors varied its form according to their fancy. Manuel Palæologus, who was crowned in 1363, is represented wearing a close crown studded with pearls. (See Du Cange, 'Hist. Byzant.,' p. 242.) The trefoil upon the crown is thought to be of Gothic introduction. We find it on the crowns of Clovis and his sons, which has induced antiquaries to call it the fleur-de-lis (Montfaucon, 'Monum. de la Mon. Fr.,' p. xxviii. Diss. prelim.), but the truth is, these trefoils were used on Constantinopolitan crowns before the time of the Franks (Ibid., p. xxxii.), and afterwards on those of German princes no way allied to Charlemagne. (See Montf. i., xxxiii.)

Crowns were placed on the statues and images of the heathen gods, as well as worn by the priests in sacrificing. Some antiquaries have even thought that the crown was originally rather a religious than a civil ornament; and that it only became common to kings, inasmuch as the ancient kings were priests as well as princes.

In regard to the crown as used in our own country, a fillet diadem of pearls appears on several of the Saxon sceattæ; upon one or two others a radiated diadem occurs. (See Ruding's 'Annals of the Coinage of Britain,' pl. 6, 7.) Similar diadems or fillets adorn the heads of many of the Heptarchic kings, and continue as the most common crown upon our coins through the whole of the Saxon series. The circle surmounted by three small projections first occurs upon the coins of Athelstan; on some of Edred's coins the projections end in pearls. A radiated cap appears first on a coin of Ethelred II., and the trefoil ornament upon the crown upon a few of the coins of Canute. Several varieties of arched cap and crown appear upon the coins of Edward the Confessor. (See Ruding's plates, 15–23.) The close or arched crown, which appears on some of Edward the Confessor's coins, is used on all the types of Harold, and was adopted by the earlier Norman kings. On Edward the Confessor's and the Conqueror's coins, we see labels appended at each ear; these, as we learn from an anecdote related by William of Malmsbury, in wearing the actual crown, were fastened by a clasp or button beneath the chin. On the coins of Stephen and Henry II., the open crown with fleurs-de-lis appears. Henry III. wears on his seals a crown fleury, pointed or rayed, the points raised, but not high, between the flowers; in his second seal the points are wanting, as on that on his tomb; but in Matthew Paris we read he was first crowned with a circle of gold. Edward I. has a similar crown on his coins and seals to that of Henry III. as well as his queen upon her tomb; so have his successors Edward III., Richard II., Henry IV. and V. Evelyn ('Numism.,' p. 34) says the monarchs of England were the first who pretended to the arched crown: that is, as it appears in modern times. Selden ('Titles of Honour,' edit. 1762, b. i. chap. 8) says he had read that Henry V. was the first of them that had a crown of the kind. In a window of Ockholt House in Berkshire, built by John Norreys, Esq., in 1465, there certainly remained, till within a very few years, the arms of Henry VI. and his queen Margaret of Anjou, in separate coats, both surmounted by the arch barred crown; from Henry VII. downward, this arched crown, with the globe and cross, has been continued.

Two of the most celebrated mediæval crowns are that of Charlemagne, preserved in the Imperial treasury, Vienna, and the iron crown of the Lombards, used at the coronation of the kings of Italy, and which is kept in the cathedral of Monza. The crown of Charlemagne "is composed of eight plates of gold, four large and four small, connected by hinges. The large ones, studded with precious stones, form the front (the central one being surmounted with a cross), the back, and the intermediate points of the crown; the small ones placed alternately with these, are ornamented with enamels, representing Solomon; David; King Hezekiah seated on his throne, having before him the prophet Isaiah; and Christ seated between two flaming seraphim, such as the Greeks usually represent them. The costume of the figures resembles that of the emperors of the lower empire, and although the inscriptions which accompany the figures are in Latin, the whole bears the impress of Greek workmanship. The ground of the figures is formed by the metal itself, which has been hollowed out to receive the enamel; but all the details of the design are traced out with fine fillets or gold by the process already described. The flesh tints are in rose-coloured enamel; the colours employed in the draperies and accessories are deep and light blue, red and white." (Labarte, 'Arts of the Middle Ages.') The iron crown of Lombardy owes its name to a ring of iron incrusted in the interior, which is reputed to have been formed from a nail of the true cross. "It is composed of a kind of collar of gold of about from 2¾ to 3 inches wide, and loaded with sapphires, rubies, emeralds, and other precious stones uncut, interspersed with flowers of gold. Apart from its antiquity, it possesses no other merit than the richness of the materials of which it is formed, and does not manifest any great artistic talent in the Lombard or Italian goldsmiths of the 6th century." (Labarte.) This crown gives its name to a famous order of knighthood, the crosses of which have, up to the present time (1859), been distributed by the Emperor of Austria. In France Louis XII. wore a single bar arched over his crown, about 1500; before, only a cap, till he married Henry VIII.'s sister. Till Francis I. an open flowery border, somewhat like our ducal coronet, was generally used. In Spain, Philip II., after he married Queen Mary, used a barred crown. In Germany, Maximilian, grandfather of Charles V., first wore an arch over a ducal coronet. In Denmark, Christian III, after he came into England, used the barred crown. James IV., on his marriage with Margaret, daughter of Henry VII., introduced it into Scotland. John Duke of Braganza was the first who used it in Portugal.

Among the Romans there were various kinds of crowns distributed as rewards for military and other achievements. The principal were the Civic, presented to a soldier who had saved the life of a citizen; the Mural, awarded to the soldier who first scaled the walls of a besieged city; the Obsidional, presented by the garrison of a beleaguered city to the commander who relieved them; the Naval or Rostral crown, given to the commander who won a naval victory; the Triumphal, worn by the general during his triumph; the Olive, conferred upon soldiers and officers by whose services a triumph had been obtained.

CROWN SOLICITOR. In state prosecutions in England the solicitor to the treasury acts as solicitor for the crown in preparing the prosecution. In Ireland there are officers called crown solicitors attached to each circuit, whose duty it is to get up every case for the crown in criminal prosecutions. They are paid by salaries. There is no such system in England, where prosecutions are conducted by solicitors appointed by the parish or other persons bound over to prosecute by the magistrates on each committal; but in Scotland the still better plan exists of a crown prosecutor in every county, who prepares every criminal prosecution whatever.

CRUCIBLE, a chemical vessel in which substances are exposed to high temperatures. Crucibles are made of various materials, forms, and sizes, and are often called *melting pots*. Earthen crucibles are used for the purpose of assaying ores, as those of lead, copper, and tin. For these purposes the refractory kind, called Hessian or Cornish crucibles, are prepared; they cannot however be employed for heating saline, alkaline, or earthy matters, as these would act upon them. Sometimes they are made of commoner and more fusible clays, when not required to withstand a high temperature. Crucibles made of porcelain are occasionally used, but they are extremely apt to crack.

Black-lead crucibles, formed of about three parts of finely-powdered plumbago, and one of good clay, are also much employed, especially in melting metals; they are more expensive than earthen crucibles, but are less liable to crack.

Glass-makers' crucibles are usually made of Stourbridge clay.

In fusing the alkalies, potash and soda, silver crucibles are used; but as they readily melt, or at least become very porous, they are not much employed for other purposes.

For chemical uses, platinum crucibles are principally employed; they withstand a high temperature, and are not in general easily acted upon. The alkalies however, and the alkaline nitrates, and the alkaline earths, act upon them; and those metals which readily fuse, such as bismuth, lead, and tin, immediately destroy them when heated in them. Care must also be taken not to expose platinum crucibles to the direct action of fuel, otherwise they become brittle and useless. They should be placed inside a common Hessian crucible, with a layer of magnesia inserted between the two crucibles. If gas be used as fuel, this precaution is unnecessary.

CRUSADES. Under this name are designated the religious wars carried on for two centuries between the Christians and Mohammedans at a time when diplomatic negotiations were unknown, and the sword decided all matters in dispute between one nation and another. The cause was ultimately lost by the Christians, who sacrificed in the struggle the lives of several millions of their brethren, though their claim was originally a reasonable one. In the beginning the Christians demanded only a free pilgrimage to the holy sepulchre, but afterwards the contest was for the possession of Jerusalem. The crusades however were by no means wars of conquest or of royal caprice; man fought against man for some higher yet mistaken principle. Hence their struggle offers something more honourable than the generality of wars, and deserves particular attention on account of its influence upon the civilisation of Europe.

As long as the caliphs of Bagdad and after them the Fatemides of Egypt possessed Palestine, the Christians were not checked in the exercise of the religious practice of visiting the holy sepulchre, which was in harmony with the opinions of that age: the Caliph Harun-al-Rashid had even the keys of the holy sepulchre forwarded to Charlemagne as a present. But when the Turks had effected the conquest of Palestine, the hospitality of the Arabs gave way to the brutality of the new possessors; the Christians were subjected to so many vexations, that the whole of Europe re-echoed with the complaints of the pilgrims; who instead of returning to their homes loaded with holy relics, brought back only wonderful tales of their insults and sufferings.

In consequence of this, Pope Sylvester II. (who died in 1003) began to preach a crusade against the Seljuk Turks for the conquest of the Holy Sepulchre. Sixty years afterwards, when only 2000 pilgrims had returned to Germany out of 7000, who had been sent to Palestine by their bishops, and the possession of Jerusalem had fallen into the hands of the Turkish chief Ortok, this untoward event filled Europe with consternation, and a desire to revenge the wrongs of the pilgrims. A single spark only was wanting to inflame the whole of the western empire to a contest with the sword for that privilege which Harun-al-Rashid had acknowledged.

Thirty years however elapsed before Pope Urban II. decreed the first crusade. First at the council of Piacenza (March, 1095), afterwards at that of Clermont in Auvergne (November, 1095), supported by the ambassador of the Emperor of Constantinople and numerous powerful lords, he proclaimed the sacred war, and appointed the 15th of August (1096), the Day of Assumption, for the departure of the army. The minds of the Christian warriors had been previously excited by the preaching of Peter of Amiens (the Hermit), and by the loud complaints of the patriarch of Jerusalem, who, provided with letters of credit from the pope, travelled through Europe, and filled all classes of society with enthusiasm for this holy warfare. Those who determined to set out for the Holy Land wore on their breast the figure of a red cross, and hence the name of Crusaders.

First Crusade.—The departure of the army having been deferred for a year, Peter of Amiens, Walter Habenichts, Count Emiko of Leiningen, and the priest Gottschalk, impatient of delay, and prompted by religious fanaticism, set out with an immense multitude, which is stated at 80,000 or 100,000 men, besides women and children, and a crowd of followers. This army, after having ill-treated and robbed the Jews in their own country, was reduced to one-third of its number in Hungary; the remainder was cut to pieces at Nicæa, in Asia Minor.

The east was now threatened with a national migration from the west. The bulk of the army was twice as numerous as that of their forerunners. It was headed by the noblest knights of those times,—Godefroy of Bouillon, duke of Lower Lorraine; Baldwin his brother; Hugo the Great, brother of the king of France; Robert, duke of Normandy, son of William the Conqueror; Raymond of St. Gilles, duke of Toulouse; and Bohemond, prince of Tarentum. The general indulgence proclaimed at Clermont, the feudal system, which led the vassals to join in the sentiments of their sovereigns, combined with the religious fanaticism of the many and the interested views of the few, created this formidable army. The pope had the address to dispose the heads of the Crusaders to acknowledge him formally as the sovereign of all the lands which they intended to conquer. The results of this expedition were of great importance. After crossing the sea into Asia, the Crusaders took possession of Nicæa in Asia Minor, and Laodicæa and Antiochia in Syria. Bohemond obtained the principality of Antiochia; Baldwin that of Edessa. New Christian principalities arose also in Tripolis, Sidon, Tyre, and other places. In the mean time Jerusalem was no longer in possession of the Turks. The Caliph Mostaali had taken it from the successors of Ortok (1096), and had again united it to Egypt, making a rival caliphat. [FATEMIDES.]

The Crusaders, however, did not allow themselves to be stopped in their victorious march by this change of circumstances: they advanced with 60,000 men, the relics of their army, against Jerusalem, besieged the town, took it (1099—June 7, July 15), and preserved it, together with all their conquests, in the great battle of Ascalon, against the Caliph of Egypt and the Seljuk chieftains. It is said that the number of slain in the conquered town amounted to 70,000. The Jews were burnt in their synagogues.

Consequences of the First Crusade. Kingdom of Jerusalem.—Godefroy of Bouillon was elected king of Jerusalem—a new state, with a considerable territory. The constitution of this new kingdom was regulated by a statute called "Les Assizes de Jerusalem." Godefroy died one year after his accession to the throne; his brother Baldwin was his successor, who was followed by Baldwin II. (1118), Fulk (1131), Baldwin III. (1148), Almerich (1162), Baldwin IV. (1173), Baldwin V. (1186), who was followed by Guido of Lusignano, who reigned till 1187, when Saladin put an end to the Christian kingdom. These kings of Jerusalem were compelled to fight with a force of only about 12,000 regular troops against the power of two mighty enemies, the Turks and the Fatemide caliph of Egypt.

Crusaders' Religious Military Orders.—The first Crusade brought two military religious orders into existence—the Knights of Jerusalem, instituted by Baldwin I., and the Knights Templars, established by the joint efforts of Hugo de Payens, Godefroy of St. Adhemar, and seven other knights. The German Knights of the Cross are of later origin.

Second Crusade.—Though the Franks had extended their possessions from the mountains of Armenia to the very boundaries of Egypt, their strength was too feeble to prevent (under the government of Baldwin III., 1144) the Atabek of Mosul from taking Edessa. The Atabeks were governors of the dynasty of the Seljuks. One of the Atabeks, named Emad-eddin Zenghi, from Mosul, having made himself independent, transmitted the kingdom to his son, Nureddin the Great, who fixed his residence in Aleppo, and became an object of terror both to the Christians and to the Fatemides. In the mean time the kingdom of Egypt had passed into the hands of Selaheddin (Saladin the Great), an event which took place under the following circumstances: In order to settle a contention about the succession, Nureddin sent a Kurd, named Shirkuh, into Egypt. The peace-maker usurped the government for himself, and bequeathed it to his brother Ayub's son, who after the death of the last of the Fatemides seated himself on the throne of these rival caliphs, and conquered Egypt, nominally for the caliphat of Bagdad. This son of Ayub was called Saladin; and the dynasty of which he became the founder is in history known by the name of the Ayubides. After Nureddin's death, Saladin conquered almost all Asia Minor, in addition to Tripolis and Tunis, and destroyed the Christian kingdom of Jerusalem.

After the conquest of Edessa, Bernard of Clairvaux took upon himself the office of Peter the Hermit, and preached a second crusade, in consequence of which two of the greatest Christian chiefs, the German emperor Conrad III., and Louis VII., king of France, were induced to take the cross (1147). For this undertaking Western Europe armed 140,000 knights and near a million of foot soldiers, and yet in spite of their mighty force the expedition failed. The changes which had taken place in the East had raised up a new enemy against the Crusaders in the emperors of Constantinople, who were less afraid of the peaceful governments of the Turks in Asia Minor and Egypt, than of the depredation and ravage which the passage of a disorderly army, such as that of the Crusaders, would cause to their possessions. Hence the artifice and treachery of the Emperor Manuel Comnenus prepared the way for the destruction of the Christian armies. The German emperor, misled by treacherous scouts, lost in the defiles of Taurus the bravest of his soldiers; the relics of his army were almost destroyed at the siege of the fortress of Iconium. The troops of the French were also defeated by the Sultan of Room, and annihilated before Damascus, a town which the Christians had in vain attempted to take by storm. The relics of the two armies united in one body (1149). Thus the expedition of the Crusaders in the East was a complete failure. The only successful result of this undertaking was the retaking of Lisbon from the Moors, which was effected by the Christian navy.

Situation of the East after the Second Crusade.—Baldwin III., however, did not give up his plans in despair. His army was at intervals increased by small bodies of Crusaders, who came to his assistance from Europe. Nureddin the Great felt more than once the power of the Christian warriors. Yet all these advantages were frustrated by the discord of the Crusaders, fomented by the rivalship of the Templars and the Knights of Jerusalem. Baldwin was succeeded by Almeric, called also Amauri, who was followed by Baldwin IV., who died likewise soon after the battle of Ramla. After his death Guido of Lusignano was completely defeated at the battle of Tiberias; he was taken prisoner, together with the grand master of the Templars, and many noble knights (1187). Saladin took possession of all the important places in Palestine, together with Jerusalem and its environs, and put an end to the Christian kingdom of Jerusalem, which had existed a century. But Saladin showed himself a generous conqueror; he granted to the Christians the possession of the Sepulchre of Christ, and allowed the prisoners to return home. The patriarch Heraclius, the clergy, the knights, and many soldiers returned to their homes, or withdrew to the few towns which the Christians still possessed on the coast of Palestine.

Third Crusade.—Bishop William of Tyre brought this bad news to Rome, which it is said caused the premature death of Pope Urban IV. The youth of Europe were again summoned to appear under the banner of the cross, not to defend the right of visiting the Holy Sepulchre, for Saladin had already granted this privilege to the Christians; but the lives of the bravest knights of Europe were to be thrown away on the insane project of again conquering the kingdom of Jerusalem. Europe obeyed the summons. The German emperor, Frederick Barbarossa, Philip Augustus, king of France, and Richard Cœur de Lion, king of England, and several German princes, enlisted themselves as Crusaders. The Italians appeared in arms under the bishops of Ravenna and Pisa. The Knights Templars, and those of Jerusalem, who were scattered about Europe, collected themselves again in strong bodies, and sailed for the Holy Land. Fifty vessels left the harbours of Denmark and Friesland, and thirty-seven those of Flanders, for Palestine. The expenses of the war were supplied by a tithe, called Saladin's tithe, which the pope ordered all Christians, including even the clergy, to pay. The Emperor Frederick I., a man of ability and experience, had found means to compel the Emperor of Constantinople to favour the undertaking. He was also engaged in negotiations with the Sultan of Iconium, who however betrayed him. By these means, and with a force of 600,000 armed men, this expedition might have succeeded; but the Crusaders did not carry on their military operations in one body. Several troops of Italian, Greek, and German adventurers, who advanced before the great army to place themselves under Conrad of Montferrat, lord of Tyre, and Guido of Lusignano, made an unsuccessful attempt to take Ptolemais (St. Jean d'Acre). Frederick I. met with a premature death by bathing in the waters of the river Cydnus, 1190. His son, Frederick of Swabia, who died soon after, put himself at the head of the relics of the imperial army, but was not able to give a favourable turn to the siege of Acre. At length Philip Augustus and Richard Cœur de Lion appeared on the battle-field. Richard had already taken and sold to Guido of Lusignano the island of Cyprus. The kings joined their armies before Ptolemais, and their united forces at last succeeded in taking this single fortress, after three years' siege and nine battles.

In consequence of these long and sanguinary struggles, the Christian army was so reduced, that the kings, despairing of success, thought of returning to Europe. Philip Augustus left Palestine soon after the capture of Ptolemais. Richard Cœur de Lion followed him after a short struggle with Saladin, with whom he made truce, and left him in possession of Jerusalem (1192). In the mean time Philip Augustus had made an inroad into Richard's dominions of Normandy. The mild, benevolent, and generous Saladin the Great died 1195, in Damascus, in his fifty-seventh year. During this crusade there arose a new military order, called the German Cross Knights, whose first grand master was Henry Walpode.

Situation of the East after the Third Crusade.—Conrad of Tyre had married the sister of Baldwin II., and thus acquired a claim upon the throne of Jerusalem. Guido of Lusignano, however, had already assumed this title. Conrad died by the hand of assassins. His widow afterwards married Guido's brother, and the two brothers assumed the title of kings of Jerusalem. One of them, named Almeric, died likewise, and the imaginary crown of Jerusalem was the inheritance of John of Brienne, the husband of the daughter of Conrad king of Tyre (1210).

Fourth Crusade.—Isaac Angelos, the Emperor of Greece, was robbed of his throne and deprived of his eyes by his own brother (1194). His son Alexius fled to Venice to ask for assistance (1203). In the mean time the enthusiast Fulk of Neuilly and Pope Innocent III. had prepared for a new crusade, which was headed by several Italian and French noblemen, such as Thiebauld of Champagne, Count Boniface of Montferrat, Count Baldwin of Flanders, and Simon of Montfort. The Doge of Venice, Arrigo Dandolo, induced the crusaders to take the town of Zara in Dalmatia for the republic of Venice. The Crusaders, probably at the instigation of Dandolo, instead of waging war against the infidels, took an active part in the affairs of Greece, conquered Constantinople, and after having elevated to the throne or deposed several emperors, at length put the imperial crown upon the head of Baldwin of Flanders, giving him the fourth part of the empire, and dividing the rest among themselves.

This behaviour drew upon them the popish interdict, which, however, was of no long duration: Pope Innocent absolved them. Thus the chief of the Franks ruled for about fifty years over the empire of the East, around which arose three new Greek principalities, Nicæa, Trebizond, and the despotat of Ætolia. This crusade was a complete failure.

Situation of the East after the Fourth Crusade.—After the insignificant crusade of Andrew, king of Hungary (1217), John, king of Jerusalem, led his army against Egypt (a plan which was certainly calculated to ensure the conquest of the Holy Land), and took Damietta. The sultan, Melek Kamel, fearing the consequences of a war, proposed peace and an exchange of Jerusalem for Damietta. The proud conqueror refused the offer, and proceeded without caution along the Nile towards Cairo. The sultan ordered the dikes of the Nile to be opened; the waters destroyed a large part of the Christian army, freed Damietta, and secured cessation from war for eight years, and the retreat of the relics of the Crusaders (1221).

Fifth Crusade.—Frederick II. of Hohenstauffen, the greatest of the German emperors, the husband of Yolanta the daughter of John of Jerusalem, had pledged himself at his coronation (1215) to a crusade. The affairs of the state, however, retarded for twelve years the fulfilment of his promises. At length, yielding to the pressing invitations of Pope Gregory IX., he sailed from Brindisi for Palestine. But after a few days' voyage, sickness compelled him to return to Otranto. This drew upon him the anger of the pontiff, who laid him under an interdict. Perhaps this was but a plausible pretext for humiliating the hated house of Hohenstauffen. Though under the pope's interdict, the emperor again appeared next year in arms in the Holy Land, which gave the pope an opportunity of allowing his enemies to invade the emperor's Italian dominions. Even John of Jerusalem was faithless and audacious enough to occupy by force the kingdom of Naples.

The sultan, Melek Kamel, set no great value upon the possession of Jerusalem, and was willing to exchange it for an alliance with Frederick against his enemy the Sultan of Damascus. Frederick, pressed by his Italian affairs, profited by the good intentions of the sultan, and obtained from him the posession of the capital of Palestine. After putting upon his head the crown, he marched homewards with his army, and his approach to the Vatican was enough to determine the pope to take away the interdict.

Situation of the East after the Fifth Crusade.—The Khowarzm-shah Turks, pressed by the Mongols, who soon after put an end to the Caliphat, rushed into the Holy Land, and defeated near Gaza the whole of the Christian forces (1244). Jerusalem, together with Palestine, became a possession of the sultan of Egypt, as a member of their alliance.

Sixth Crusade.—Louis IX., king of France, called St. Louis, undertook in the year 1249 a new crusade. He followed the plan adopted by John of Jerusalem, and conducted his army against Egypt.

This land, however, seems to have offered few advantages to the Christian conquerors. Louis, after having easily obtained possession of Damietta, marched along the Nile towards Cairo, but, chiefly through the imprudence of his brother d'Artois, he lost the battle of Mansura, and with it the bulk of his army. D'Artois and many of the bravest knights were slain; hunger and sickness compelled the remainder to retreat. Before they were able to reach Damietta, they saw themselves overtaken and surrounded by the sultan, who made the king prisoner, together with the relics of his army. A truce was agreed on, in which the Christians were compelled to give up Damietta, and to pay a ransom of 800,000 Byzantine guilders. The Mamluks, a guard composed of Turkoman youth, who had gradually increased in power, dissatisfied with the generosity of the sultan towards the Christians, murdered him, and placed Ibek, their commander, upon the throne of the caliphs of Egypt. Louis, however, after some hesitation, was allowed to obtain his liberty.

Though Louis, upon his return to France, found his kingdom in a disordered state, on account of the misery and waste caused by the revolutionary movements of bands of a fanatic peasantry called Pastorells, he could not give up the idea of reconquering Jerusalem, and a few years after his return he prepared a new crusade. This crusade, however, did not extend beyond Tunis, where Louis expected to make converts of the princes. This undertaking failed likewise; and Louis found his grave on the shores of Africa (1270).

Seventh Crusade.—England was the pioneer of the seventh and last crusade. While Louis was still in Tunis, Edward, the grandchild of Richard Cœur de Lion, prepared a new crusade. After the death of Louis he appeared before Tunis, but soon left Africa for Palestine to fight against the Saracens. Not being able to accomplish his plans he returned home, and was the last among the Christian princes who dreamed of conquering the Holy Land.

Situation of the East after the last Crusade.—A few towns situated on or near the coast, Antioch, Ptolemaïs, and Tripolis, were still in possession of the Christians, and were chiefly defended by the Templars and other military orders. The dispute about the kingdom of Jerusalem still continued between the descendants of the Baldwins. At length Ptolemaïs fell (1291); the other towns were either abandoned or taken; the knights fled to Europe, and the whole of Palestine and Syria again became a possession of the sultans of Egypt, and obeyed the laws of Mohammed. In short, the labour of two centuries was lost; and we may regard this epoch as a kind of oriental restoration.

Crusades in the Western Empire.—We have already observed how Emiko of Leiningen and the priest Gottschalk had persecuted the Jews in the Rhenish provinces in their expedition towards the East. This was called a crusade against the Jews. The banner of the cross was likewise displayed in the wars against the Moors in Spain, against the heathens in Prussia and Lithuania, against the Waldenses and Albigenses in France, against all kinds of heretics, even against the house of Hohenstauffen, when placed under the popish interdict; which wars, unjust in their principle, were rendered by fanaticism still more terrible in their consequences.

Object of the Eastern Crusades.—The object of the first crusades was to obtain possession of the Holy Sepulchre for the Christians in Europe; and secondly, to protect the Christians in the East against the persecutions of the Turks. The first object might perhaps have been obtained by treaties: the second, however, could not be secured as long as the Turks possessed Palestine; and hence the conquest of this country became the principal object of the crusaders. This conquest might have been made in favour of the lawful lords of Palestine, the caliphs, but the Franks, misled by fanaticism, preferred to take for themselves that which by right belonged to others, and by a just retribution lost the fruits of two hundred years' struggle. On the other hand, if they had been guided by moderation, they might have easily obtained from the caliph Mostaali the possession of Jerusalem by treaties.

The object of the second crusade was from the very beginning inconsiderate. The possession of Jerusalem was not in danger; nothing had happened to cause a war, except the taking of Edessa.

The third crusade was undertaken with the view of reconquering the Holy Land. This war may appear just to those who think that the acquisition by the sword and the possession of a few years make a good title; or even to those who, misled by diplomatic sophistry, fancy that crowns and men may be inherited like goods and chattels. The crusade of Count Baldwin was an infamous intrigue and mystification of the Doge Arrigo Dandolo: the crusade of the king of Jerusalem was an idle attempt to change his imaginary crown into a real one by taking the towns of Egypt; neither of these expeditions deserves the name of crusade, a name that might be given with more propriety to the fourth crusade undertaken by Andrew, king of Hungary.

The hatred of the pope against the house of Hohenstauffen was the cause of the fifth crusade. In spite of the impure motives of this war, however, the emperor, by his prudent conduct, succeeded in obtaining the possession of Jerusalem without the sacrifice of time or blood.

The sixth and seventh crusades were undertaken with the object of regaining possession of Palestine, which had been lost in the battle of Gaza. The chief reason why so many powerful expeditions turned out signal failures may be sought in the rivalry of the knights of the same country, and the jealousy of their respective kings; hence there was no unity of action, no discipline, no commander-in-chief, and their numerous armies were scattered and defeated like sheep without a shepherd.

Consequences of the Crusades.—Though the crusades sacrificed the lives of several millions of Christians, among whom were many women and children, and though they were one of the causes which contributed to give the popes such an overwhelming power in Europe, although they were instrumental in bringing about the religious wars or persecutions which afflicted Europe, and also in weakening the power of the eastern princes, and rendering them unable to withstand the attacks of the Mongols, it cannot be denied that the crusades were accompanied by many beneficial effects.

Such, for instance, were the increased activity of political life in Europe, the union of different nations in a common object, the consequent dissipation of international strifes and prejudices, and a tendency to a more humane reciprocal intercourse, the acquisition of scientific knowledge, improvement in manners and habits, the breaking up of the feudal system by the sale of estates to the merchants in exchange for the money required by the nobles for their military accoutrements and provisions, the increased wealth of the mercantile towns in Italy, which led to the revival of the fine arts and the sciences in that country, and finally, the diffusion of more liberal modes of thinking in matters of government and religion, occasioned by the intercourse of the western and eastern nations. The great influence of the crusades in extending commerce has been pointed out by Heeren in his 'Essay on the Influence of the Crusades.'

Before the crusades the heavy clouds of religious fanaticism hung over Europe, and mankind bore quietly the chains imposed upon their minds by the authority of the priesthood. But the knight and the soldier who returned from the crusades, after having a thousand times experienced the generosity and hospitality of the Musselmans, brought home the singular tale that in those remote countries there existed a race of men noble-minded and kind, though professing a creed different from that of their invaders.

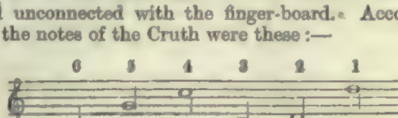
Blind submission to the authority of the priesthood was exchanged for meditation and independent reflection. The inquisition, which was instituted about this time, proves that there were men who were deemed fit subjects for an inquisition, that is, heretics and philosophers. One or two centuries after the crusades, Europe was filled with religious sceptics, as far as regarded the infallibility of the church, some of whom even dared to be religious reformers, such as Huss, Wycliffe, and others. At length Luther appeared, who by his theses and his translation of the Bible shook the very pillars of the Vatican.

Since the reformation of Luther, the Christian religion has been split into numerous sects, an event which some regard as injurious to religion. But as, in the chemical process of fermentation, in order to prepare a new and better product, it is necessary that the old matter be dissolved into minute particles (that the grape, for instance, be pounded and reduced to an unsightly juice, in order to make a pure and costly wine), so it is perhaps necessary that Christianity should be divided into many sects in order to clean it from all accidental impurities, and to make it fit to become the universal religion of mankind.

(Wilken, *Geschichte der Kreuzzüge*, Leipzig, 1807; Voltaire, *Histoire des Croisades*; Michaud, *Histoire des Croisades*; Robert Mons, *Historia Hierosolomitana*: Gibbon's *Decline and Fall of the Roman Empire*; Mill's *History of the Crusades*; Sybel, *Geschichte der erste Kreuzzüge*, 1841; and lastly, Michaud, *Bibliographie des Croisades*, which gives an account of all the writers who have treated this subject.)

CRUSCA, ACADEMIA DELLA. [ACADEMY.]

CRUTH, or CRWTH, a musical instrument of the violin kind, formerly much used in Wales. Sir John Hawkins says that "it somewhat resembles a violin, twenty-two inches in length and an inch and a half in thickness. It has six strings, supported by a bridge, and is played on by a bow. . . . . . . The bridge is not placed at right angles to the sides of this instrument, but in an oblique direction, and one of the feet passes through one of the sound holes, and rests on the inside of the back." The four first strings are placed as in the violin, but the fifth and sixth, which are an inch longer than the others, are fixed to the upper part of the instrument in the manner of the arch-lute [LUTE], and unconnected with the finger-board. According to the same writer the notes of the Cruth were these:—



from which we are led to suppose that the strings were struck in pairs—two at a time.

The word Cruth was corrupted in pronunciation into *crowd;* hence a performer on the instrument was called a crowder. Butler, in 'Hudibras,' names his fiddler *Crowdero.* (Hawkins' 'Hist.' vol. ii.)

CRUX, a southern constellation formed out of Halley's observations, by Augustin Royer, in his maps, published in 1679. It is situated close to the hinder legs and under the body of Centaurus.

The following are the principal stars in this constellation:—

Character.	No. in Catalogue of British Association.	Magnitude.
δ	4120	3
ϵ	4158	4
α^2	4187	1
γ	4215	2
β	4289	2

CRY'OPHORUS, from the Greek words *κρύος* (cold) and the root of *φέρω* (to bear), is an instrument which was invented by Dr. Wollaston for the purpose of exhibiting the congelation of water in consequence of evaporation.

It consists of a glass tube about nine inches long, bent near the two extremities, and terminating with hollow balls of the same material. One of these balls is about half full of distilled water, which being made to boil, the air is expelled, the tube together with the other ball becoming filled with aqueous vapour: in this state the tube is hermetically sealed. The expansive force of the vapour, by producing a pressure on the surface of the water, prevents any further evaporation from thence; but, on plunging the ball containing no water into a mixture of snow and salt, the vapour in the balls and tube is suddenly condensed and a vacuum is produced, when an evaporation immediately takes place from the water, and the latter, in two or three minutes, is converted into ice.

CRYPT, a vaulted chamber, chiefly or entirely under ground. The term crypt is now almost exclusively applied to the vaults under churches and cathedrals; but as originally used, in reference to Roman buildings, it had a much more extended application, being employed for any low, narrow, underground vault. Thus, what would now be termed a tunnel, the carceres of a circus [CIRCUS], and even cloacæ [CLOACUS], were called *Cryptæ* (from *κρύπτειν, to conceal*). From forbidden rites or forms of worship being frequently performed in these underground chambers, they came to be commonly designated cryptic in reproach. The rites of Priapus were so spoken of; so also was the worship of the early Christians, who were accustomed to meet together in the catacombs of Rome [CATACOMBS] during the age of persecution. An arcade or portico enclosed at the side by a wall for protection from the sun and rain was called a *Crypto-Porticus.*

The crypts constructed under the older churches and cathedrals were intended to serve as chapels, and for the performance of certain rites and services,—no doubt in commemoration of the fact of the practice of the early Christian Church in its time of suffering. They have also in many instances been used as places of sepulture, or receptacles of the monuments of the dead, as at the abbey of St. Denis. In the crypts of several English churches human bones are found piled up with great regularity, and without any more than a vague and often manifestly unfounded tradition of the date at which they were placed there. Instances of this kind occur at Hereford Cathedral, Ripon Minster, Hythe Church, Kent, Christchurch, Hampshire, &c.

The vaulting in Norman, or Romanesque, and Gothic crypts is commonly supported on low massive columns and the basement walls of the church. Usually the crypt occupies but a part of the area of the church, usually the choir or chancel, but sometimes, as at Christchurch, one or both of the transepts. One of the largest and finest crypts in England is that under Canterbury Cathedral. [CHURCH.] In most of our cathedrals, and more important collegiate and parish churches, which have been rebuilt or enlarged at different times, the crypt is the oldest part of the structure. During the Norman period great attention was paid to the formation and enrichment of the crypt for the purposes of worship; but gradually it came to be regarded as of less and less importance, and no new ones appear to have been constructed after about the middle of the 13th century. One of the latest of these subterranean churches in England, the finest of its time, is that under Rochester Cathedral, which, with the choir, was rebuilt at the beginning of the 13th century. Several of the French and German Gothic churches have very fine crypts.

CRYPTIDINE ($C_{22}H_{11}N$). An organic base found in coal tar.

CRYSTALLINE. [ANILINE.]

CRYSTALLISATION. When a liquid is about to assume the solid state, and by the gentle application of heat or by its slow withdrawal the particles are drawn very gradually under the influence of cohesion [ATTRACTION], they do not form a confused amorphous mass, but in many cases arrange themselves into geometrical solids of great beauty and symmetry. Thus, if a mass of sulphur or of bismuth be melted, and allowed to cool slowly, so as to form a crust over the surface, if this crust be pierced and the liquid portion poured out, the cavity will be studded, in the case of bismuth, with beautiful cubic forms, and in the case of sulphur, with six-sided prisms and needles. These forms are called crystals, and the process is termed crystallisation. For the forms of crystals, see CRYSTALLOGRAPHY, in NAT. HIST. DIV.

CUBE (*κύβος*), a solid figure contained by six equal squares; a box of equal length, breadth, and depth.

Owing to its being the most simple of solids, the cube is the measuring unit of solid content, as the square is that of superficial content, or area. Whatever the unit of length may be, the unit of solidity is the cube which is a unit every way: thus we have the cubic inch, the cubic foot, &c.

Cubes of different sides are to one another as the algebraical third powers of the number of units in their sides: thus cubes which are as 7 to 10 in their sides are as $7 \times 7 \times 7$ to $10 \times 10 \times 10$ in their contents. Hence the algebraical third powers are called cubes; thus $a \times a \times a$ is called the *cube* of a. If the side of a cube contain a units, the content is $a \times a \times a$ cubical units of the same kind.

The cube has no *remarkable* properties, for our eyes are so used to the figure, that its properties seem self-evident.

Its internal diagonals are found by multiplying the number of units in the side by $\sqrt{3}$, or (very nearly) by adding one half and one half of one half, and subtracting one per cent. of the result, and if still further accuracy be required, 5 for every 10,000 units:—

```
2)10000 subtract 5 presently.
2) 5000
   2500
  ------
  17500
    175
  ------
  17325
      5
  ------
  17320 feet in the diagonal
```

which is about six inches too small.

For the celebrated historical problem connected with this article, see DUPLICATION OF THE CUBE.

CUBEBENE ($C_{30}H_{24}$). An oily body isomeric with oil of cubebs, from which it is obtained by distillation with concentrated sulphuric acid.

CUBEBIN ($C_{34}H_{16}O_{10}$?). A non-azotised principle found in cubebs. It crystallises in groups of small needles, which are colourless and tasteless. It is only slightly soluble in cold water, alcohol, or ether, but is much more soluble in boiling alcohol. Concentrated sulphuric acid strikes a red colour with cubebin.

CUBIT, a measure of length in use among the ancients, and more especially among the Jews. The Hebrews called it אמה (*amma*), as the mother of other measures; the Greeks Πῆχυς (*péchus*); the Romans *Cubitus*, a word apparently formed from the verb "cubo," to bend for the purpose of lying down. The cubit was originally the distance from the joint or bending of the elbow to the extremity of the middle finger.

The best authorities assert that there were two cubits in use among the Hebrews; one sacred, the other common. In Deuteronomy, chap. iii. v. 11, the bed of Og is said to be nine cubits long and four broad, *after the cubit of a man.* The common cubit was eighteen inches; the sacred or great cubit (Ezek. xli. 8; and xliii. 5) of twenty-one inches, is stated to be a cubit and a hand-breadth. Calmet, however, is persuaded, that from the Exodus to the Babylonish captivity, there was but one cubit in use among the Hebrews, and then it was the Egyptian cubit. He says it is only *after* the captivity that Scripture notices two sorts of measures, to distinguish the old Hebrew cubit from that of Babylon, which the captives used during their abode in that city. On this, he adds, is grounded the precaution of Ezekiel, in observing that the cubit he is speaking of is the true old cubit, larger by a hand's breadth than the common cubit. There is no means of positively ascertaining the precise length of the cubit; the common cubit is stated to be 1 foot 9·888 inches, and a hand-breadth 3·684, in the table of Scripture measures inserted in some editions of the authorised versions of the Bible. This of course is Ezekiel's cubit. Among the Greeks the cubit (*péchus*) was twenty-four fingers (*δάκτυλοι*), measured as already explained. See Herodotus, ii. 175. (Arbuthnot, 'Tables of Coins, Weights,' &c.; and Calmet's 'Dict. of the Holy Bible,' in voce.)

CUCKING STOOL, a machine formerly used for the punishment of scolding women, consisting of a stool or chair attached to the end of a long pole, mounted in such a manner that the chair, with the offender placed in it, might be swung over a pond, and immersed as often as might be necessary. Several notices of the use of this apparatus, which was also called a *trebuchet*, a *tumbrel*, or a *ducking-stool*, are given in Brand's 'Popular Antiquities.' It appears to have been used as early as the era of the Saxon government in England, and to have been a common punishment, in some places at least, as late as the time of Gay, who mentions it in his 'Pastorals.'

CUCUMBER, a trailing annual, whose unripe fruit is used for salads and pickles. [CUCUMIS.] Every gardener knows so much of the cultivation of this plant as to render any general description of the process unnecessary. We only notice a few points. The finest cucumbers are always obtained from shaded plants growing in a warm damp atmosphere, and therefore growing rapidly; this is exclusively owing to the ordinary action of solar light being prevented. Under bright light, evaporation goes on with great force from the surface of the cucumber plant, the quickness of growth is thus diminished, and the fruit is formed in a more solid manner than it otherwise would be, and thus its delicacy is impaired. The effect of direct light moreover is to cause the production of whatever secretions may be natural to a plant; the natural secretions of the cucumber are bitter; hence, the less cucumbers are exposed to direct light while growing, the less bitter, and consequently the more delicate they will be. This sufficiently explains the superiority of cucumbers forced quickly at the dull season of the year, to those produced naturally in the open ground in autumn.

When it is an object to procure very fine and long fruit, the plant should not be allowed to bear early; all the female blossoms should be destroyed until the plant has become vigorous, and well rooted in the bed; a fruit set after that time, will grow much faster than one fertilised at an earlier time.

The best sorts of cucumbers are, for gherkins, the *Russian;* for stewing, the *large white Bonneuil;* for large size, the *Longford;* and for ordinary forcing purposes, any of the *long prickly* sorts, whether *black spined* or *white spined.* The *Smyrna,* which is spineless, and a great bearer, is not in favour with gardeners, for what reason no one can tell. A small sort called the *Sandy* cucumber is grown in the fields in some parts of Bedfordshire, but it is altogether inferior to the *Russian.* A fine table cucumber should have no ribs, be perfectly straight, and the end next the stalk should be as thick as the other end.

CUDBEAR is a violet red powder used in dyeing wool and silk, to which it communicates various shades of brown and purple. It is prepared from the same lichens as archil [Archil] and litmus [Litmus]; for a list of them see Lichens, *Colouring matters of.* They are first reduced to a pulp with water, and then treated with ammoniacal liquor from gas-works, or with stale urine to which lime has been added to set free ammonia, constant agitation being kept up in order that the whole may be well exposed to the air. The expressed liquor is either sent into commerce under the name of archil, sometimes called *liquid cudbear;* or thickening materials, such as chalk, plaster of Paris, &c., are added to it, and it is then dried, powdered, and sold as *cudbear,* or less frequently as *persio.*

The colouring matters of cudbear consist of some very beautiful crystalline compounds. [Lichens, *Colouring matters of.*]

Cudbear derives its name from Dr. Cuthbert Gordon, who first made it an article of trade in this country, at the commencement of the present century.

CUIRASS or **CUIRASSE**, a piece of defensive armour, made of plate well hammered, serving to cover the body from the neck to the girdle, both before and behind; the front called the breast-, the hinder part the back-plate; these were fastened to each other by straps, buckles, hooks, or some other contrivance. The name is supposed to be derived from *Curatia* or *Curassa,* a Latin word of the middle age, which occurs in charters at least as early as the 14th century (Meyrick's 'Glossary of Military Terms'), originally derived from the French *cuir* or the Latin *corium,* "a hide," the earliest cuirasses being made of leather, though afterwards chiefly of metal, both brass and iron.

This species of armour was known to the Greeks and Romans. A breast- and back-plate of Roman workmanship are preserved among the Hamiltonian antiquities in the British Museum, which, when worn, appear to have been held together by strings or wires, fastened to nipples in front. In later ages the cuirass was disused, and was not revived in Europe till about the beginning of the 14th century. In England it was disused after the reign of Charles II., except in one instance; but has of late years been revived for our cavalry. The cuirass was stated, in Col. Lygon's evidence before a committee of the House of Commons on army and navy appointments, in 1833, to have been introduced as a part of the accoutrements of the Life-Guards within the preceding twelve years. To a question, "Can you state what was the purchase-cost per man of the cuirass?" he answered, "I apprehend they cost nothing; they have been lying in the Tower for years, and were worn at the battle of Dettingen."

In the Romish calendar, under October 14, we find the name of St. Dominic, who is called *loricatus* or the cuirassed, a title given to a saint of the 11th century, who constantly wore an iron cuirass next to his skin.

CUIRASSIERS, heavy cavalry armed with cuirasses. Most of the German powers, especially the emperor of Austria and the king of Prussia, have regiments of cuirassiers. They also form a portion of the French cavalry. In England we have no regiments which go by this denomination, although what are called the life-guards now wear the cuirass. [Cuirass.]

CULDEES, the name of a religious order in Scotland, Ireland, and the north of England, whose origin may be dated from the middle of the 6th century. The information regarding their origin is chiefly derived from the memoirs of their founder Columba. Their gradual absorption, by the spread of the Roman hierarchy in Scotland, is shown very clearly in the chartularies and other muniments of the episcopal sees and abbacies in Scotland. There have been so many etymologies of the word Culdee, and they are all so purely hypothetical, that it would be a useless effort to attempt a comparative judgment on them.

Unfortunately, the history and institutions of the Culdees have been the subject of dispute between the supporters of the Episcopal and those of the Presbyterian form of church polity: the one maintaining that this primitive body were a mere collection of monastic institutions connected with the Catholic hierarchy; while it is endeavoured to be proved, on the other side, that they were the prototypes of the Protestant Presbyterians, and that their church polity was derived from the fountain-head of Christian truth, and communicated to modern times through the Lollards, before the Culdees were entirely extinguished. They have in this respect been compared with the Waldenses. The Culdees undoubtedly formed a part, if not the whole, of that early Scottish Church, which had established a different epoch for the celebration of Easter from the Western Church,—a subject subsequently productive of much dispute between the Scottish and English ecclesiastics. The ground on which the former maintained their own peculiar usages was, that they had been derived directly from the apostles, by whom, and not by the ecclesiastical representatives of St. Peter, the Church in Ireland had been planted. The practice of the Culdees seems to have so far coincided with the later monastic institutions, that they lived in retirement, practised abstinence, and made devotion and the administration of religious and charitable functions their chief pursuits. So far were they, however, from adopting a rule of celibacy, that marriage was practised and reckoned honourable among them. It is difficult to discover their precise polity. It has been found that they ordained bishops; but it farther appears that the persons bearing that name, instead of having any absolute authority over another class as Presbyters, were themselves under the authority of the president, or head of the establishment, as representing the community. The Culdees had establishments in various parts of Scotland, many of them in the form of colleges, where they kept small libraries of manuscripts, and gave instruction to youth. Their principal establishments, besides that of Iona, were at Oronsay, Abernethy in Perthshire, the island of St. Serf in Lochleven, Dunkeld, St. Andrew's, and Monymusk in Aberdeenshire. Efforts have been made, though apparently without success, to identify these establishments with the episcopal dioceses, and to prove that each college or monastery, with its head and ordinary members, was virtually the dean and chapter of the diocese; but it is better supported that the first bishops were Culdees, and that they were elected from among the pastors by the votes of this body. The archiepiscopal see of St Andrew's appears to have owed its early predominance to the Culdees, who seem to have had considerable possessions in the neighbourhood. The great abbey of Arbroath is believed to have had a similar origin, and so is that of Melrose. Besides the dispute as to the holding of Easter, and the difference of opinion on the marriage of ecclesiastical persons, the Culdees had many subjects of dispute with the Romish hierarchy, from whose customs they seem to have diverged on the subject of auricular confession, and various others. They were at last obliged to give way before the waxing influence of the Church of Rome. St. Bernard describes the people as beasts and barbarians, who "neither pay tithes nor first fruits. They do not enter into lawful marriage; they do not go to confession; no one can be found who applies for the prescription of penance, nor any one who will prescribe it." The erection of the several bishoprics, under the patronage and countenance of the kings of Scotland, raised up powerful enemies to the Culdees who were within the respective territories allotted to them as dioceses, and the order was thus gradually incorporated with the Romish Church.

(Jamieson, *Historical Account of the Ancient Culdees of Iona, and of their Settlements in Scotland, England, and Ireland,* 4to, Edinb. 1811; Maccallum, *History of the Culdees,* 12mo, Edinb. 1855; Keith, *Catalogue of Scottish Bishops.*)

CULMINATION (*culmen,* the summit of a thing). A star culminates, or comes to its highest point, at the moment when it is on the meridian. [Transit; Meridian.]

CULVERIN. [Artillery.]

CUMENE. [Cuminic Acid.]

CUM-EUGENYL. [Caryophillic Acid.]

CUMIDINE. [Cuminic Acid.]

CUMINAMIDE. [Cuminic Acid.]

CUMINIC ACID ($C_{20}H_{12}O_4$). Cuminic acid and its derivatives form a group of bodies which are entirely homologous with the benzoic acid group.

Cuminic Aldehyde, Hydride of Cumyl, Cuminol ($C_{20}H_{12}O_2 = C_{20}H_{11}O_2H$). This body, which is the starting point for the preparation of most of the cuminic derivatives, exists in a free state in the etherial oil of cumin (*Cuminum cyminum*), along with a hydrocarbon cymole. When this oil is treated with an alkaline bisulphite, a crystalline compound of the aldehyde with the bisulphite is formed, and this compound, freed from foreign substances by pressure between bibulous paper, yields on subsequent treatment with potash, hydride of cumyle.

When pure, hydrate of cumyl is a colourless or slightly yellow liquid, with a strong odour of cumin, and a bitter acrid taste. It boils at 428° F. Exposed to the air, or still more rapidly when treated by oxidising agents, it assimilates oxygen, and becomes converted into cuminic acid. Treated by potassium, hydrogen is liberated, and *cumylide of potassium* ($C_{20}H_{11}KO_2$) is formed.

Cuminic Acid ($C_{20}H_{12}O_4 = HO, C_{20}H_{11}O_3$). When hydride of cumyle or oil of cumine is dropped on fused hydrate of potash, hydrogen is liberated, and cuminate of potash is formed:—

$$\underbrace{C_{20}H_{12}O_2}_{\text{Hydride of Cumyl.}} + \underbrace{KO\,HO}_{\text{Potash.}} = \underbrace{KO, C_{20}H_{11}O_3}_{\text{Cuminate of Potash.}} + 2H$$

When the fused mass is dissolved in water and decomposed by hydrochloric acid, the cuminic acid is precipitated, and after crystallisation from alcohol is obtained in the form of beautiful colourless plates. It is a monobasic acid; its salts have the general formula $C_{20}H_{11}MO_4$. They are of little importance.

When cuminic acid is treated with nitric acid there is formed, according as the action is modified, *nitrocuminic acid* ($C_{20}H_{11}(NO_4)O_4$), or *binitrocuminic acid* ($C_{20}H_{10}(NO_4)_2O_4$). By the action of pentachloride of phosphorus, the *chloride of cumyl* ($C_{20}H_{11}O_2,Cl$) is formed:—

$$\underbrace{C_{20}H_{12}O_4}_{\text{Cuminic acid.}} + \underbrace{PCl_5}_{\text{Pentachloride of phosphorus.}} = \underbrace{C_{20}H_{11}O_2,\ Cl}_{\text{Chloride of Cumyl.}} + HCl + \underbrace{PO_2Cl_3}_{\text{Oxychloride of phosphorus.}}$$

This is a colourless liquid, which fumes in moist air, and boils at 493° F. By water it is decomposed into hydrochloric acid and cuminic acid, and by ammonia into *cuminamide* ($C_{20}H_{13}O_2 = N\left\{\begin{matrix}H\\H\\C_{20}H_{11}O_2\end{matrix}\right)$. Cuminamide is also formed when cuminate of ammonia is distilled. It resembles benzamide.

Anhydrous cuminic acid ($(C_{20}H_{11}O_3)_2$) is formed by the action of chloride of cumyl on cuminate of soda. It closely resembles the corresponding benzoic compound.

Cumole ($C_{18}H_{12}$), *Hydride of Cumenyl, Cumene*, is formed when cuminic acid is distilled with excess of caustic baryta:—

$$\underbrace{C_{20}H_{12}O_4}_{\text{Cuminic acid.}} + \underbrace{2BaO}_{\text{Baryta.}} = \underbrace{2BaO\ CO_2}_{\text{Carbonate of baryta.}} + \underbrace{C_{18}H_{12}}_{\text{Cumole.}}$$

It also exists in coal-tar naphtha, from which it is separated by fractional distillation. It boils at 292° F. It is homologous with benzole, which it greatly resembles, and under the influence of various agents it undergoes a series of changes exactly similar to those of that body. Thus, there exists a *nitrocumole* ($C_{18}H_{11}NO_4$), and *binitrocumole* ($C_{18}H_{10}(NO_4)$). The former, under the influence of reducing agents, is converted into a compound ammonia, *cumidine*, ($C_{18}H_{13}N = \left.\begin{matrix}C_{18}H_{11}\\H\\H\end{matrix}\right\}N$) an oily liquid, which with acids forms crystallisable salts. There is also a *sulphocumenic acid* ($C_{18}H_{12}S_2O_6$), homologous with sulphobenzolic acid.

Cuminic Alcohol ($C_{20}H_{14}O_2$). When cuminic aldehyde is treated with potash ley of moderate concentration, it undergoes a change analogous to that experienced by its homologue, benzoic aldehyde, under the same circumstances, being converted into cuminic acid, and cuminic alcohol:—

$$\underbrace{2(C_{20}H_{12}O_2)}_{\text{Cuminic aldehyde.}} + \underbrace{KO\ HO}_{\text{Potash.}} = \underbrace{C_{20}H_{11}O_3KO}_{\text{Cuminate of potash.}} + \underbrace{C_{20}H_{14}O_2}_{\text{Cuminic alcohol.}}$$

This alcohol is a colourless liquid, with a feeble aromatic odour, and an acrid taste. It is insoluble in water; it boils at 470° F. Like its homologue, benzoic alcohol, with which it has great similarity, it has all the properties of an alcohol. It decomposes under the influence of reagents into products analogous to those furnished by ordinary alcohol, the difference being that from the greater complexity of the molecule it is more difficult to produce these changes.

CUMINOL. [CUMINIC ACID.]

CUMOLE. [CUMINIC ACID.]

CUMONITRILE ($C_{20}H_{11}N$). This body, which is the cyanide of cumenyl ($C_{18}H_{11}Cy$), is obtained by heating cuminate of ammonia. It is a colourless oily body, of an agreeable odour.

CUMYL ($C_{20}H_{11}O_2$). The hypothetical radical of cuminic acid. [CUMINIC ACID.]

CUMYL-SALICYLAMIDE ($C_{34}H_{17}NO_6$). A crystalline amide obtained by the action of chloride of cumyl upon salicylamide. [AMIDES.]

CUNEIFORM or CUNEATIC. These words, as well as arrow-headed, nail-headed, and wedge-formed, describe the oldest written characters used in the country about the Tigris and Euphrates, and subsequently in Persia. All refer to the strokes or elements of the characters which were thought by travellers who saw the tablets on which they were inscribed, to represent wedges or the heads of nails or arrows: they vary from a neatly formed stroke like this  to a clumsy triangular wedge. There are two distinct alphabets made up of these wedges or arrow-heads; the older one, called the Assyrian or Babylonian, consists of more than two hundred characters, in which the wedges are placed horizontally, perpendicularly, and obliquely, often crossing each other in all directions; the oblique wedge frequently becomes an angular hook, from the lengthening of one side of the head: thus,  becomes , and at length . The Babylonian differs from the Assyrian little more than the handwriting of one man from that of another. The more recent alphabet was used in Persia; it consisted of thirty-six letters only, the strokes were all horizontal or perpendicular, and with one exception they were never made to cross each other. This second alphabet is very distinctly formed in all the cases that have come down to us, no one letter is at all doubtful, and the words are separated from each other by an oblique stroke.

Of the above alphabets the older one appears on monuments dating at least twenty centuries before the Christian era, and documents are found written with it which come down to the time when Alexander's successors were ruling in Western Asia. In that long interval it underwent many modifications, which greatly disguise its identity; but a careful investigation will show that the characters do not differ more than the Roman, Italic, and old English types now in use; not so much as the variously contorted letters we see occasionally, intended by their contrivers to be ornamental. This alphabet was used in writing at least four different languages, only one of which has been studied to any great extent; it is a most cumbrous alphabet, almost equalling the Egyptian in clumsiness and imperfection. The other alphabet was used in the Persian empire only, where it appears to have been introduced by the elder Cyrus, and it is found in documents of the time of Artaxerxes Ochus; it lasted, therefore, a couple of centuries, from 540 B.C. to 340 B.C. This was a true alphabet of thirty-six letters; it is easily read, the words are separated, there is very little variety of form in the letters, and it was used solely for the principal language of the Persian empire.

It may be said that there is a third alphabet, the one used in the so-called Scythic inscriptions of Persia, but this is really a modification of the first mentioned Assyrian alphabet; it is somewhat simplified, and it rejects the more complex forms. So far as we know, it was employed solely for the Scythic versions of the inscriptions of the Achemænian dynasty; and its duration was also from the reign of Cyrus to that of Artaxerxes Ochus.

These three kinds of writing almost without exception are found together, in the inscriptions of the Achemænian period, in the Persian empire; all such monuments contain the same notice or statement in the three languages and alphabets. The writing upon the highest or most prominent tablet is called universally the first kind; we should be inclined to call it the Median writing, as being in the language of the most numerous and civilised of the inhabitants of the Persian empire, if the Median name had not hopelessly yielded to that of the Persians, the energetic race of the province of Persis, who imposed their rule upon Media, in the same way as the energetic German Franks imposed their own national denomination over all Gaul. The next in place on the monuments is that modification of Assyrian used for a Turanian language; it is called "the second kind," as well as Median and Scythic; the language may have been that of the province of Persis, and placed so high on the inscriptions as being the tongue of the native province of Cyrus. The third in place is the Babylonian; the language of the most literary portion of the Persian empire, which was necessary for the dissemination of a knowledge of the inscriptions over its western provinces. The employment of this version has proved the stepping-stone to the decipherment of the Assyrian language and character, almost identical with Babylonian, without which we are confident that the relics of Assyrian literature, found in such abundance within these few years, could never have been by any possibility understood.

All the early accounts of cuneiform inscriptions refer to the monuments of Persia; they were all visible, and in lofty places, while those of Assyria were buried among the ruins of cities, luckily far out of reach, to be found at the very moment when only could there be any hope of ascertaining their value, when a few learned scholars had succeeded, after thirty years' labour, in reading the easier monuments which were to give a clue to the intelligence of the more mysterious relics now coming into view. All attempts at decipherment had been confined, with hardly an exception, to the first kind of writing, until the labours of Layard and Botta, in and about the mounds of the long-lost, almost fabulous Nineveh, brought to the knowledge of Europe the vast treasures of Assyrian civilisation, and, in the majority of instances, not only the knowledge of their existence, but the monuments themselves; not only the great advertisements posted up on the walls of the empire, as in Persia, but thousands of the books intended to be consulted in the study. These books are closely written slabs of dried clay, from a pocket edition of two inches by one and a-half, or even less, to a quarto slab of eight inches by six. We frequently find also, barrel-shaped masses of terra-cotta, from four to seven inches long, and six to ten inches in circumference; and when the document was larger it was written on a prism of six, eight, or ten sides, from twelve to twenty inches long; one has been found in fragments, which may have been more than thirty inches long. These prisms had a hole through their length, as though intended to be mounted like a roller, and turned round to present its sides in succession to the reader. The writing on all these terra-cotta books is small, from six to ten lines in an inch, but some words are occasionally much smaller, like notes, of which sixteen at least might be included in an inch. The long-during burial of these oldest specimens of literary labour, while it has for so many centuries kept from the world such abundant sources of our knowledge of ancient history, has done us the great service of preserving these fragile relics in as perfect a condition as they were in when first buried under the ruins of Assyria; many of them are as fresh as when they came from the hands of the moulder, with the burred edge made by the writing-tool upon the soft clay still perfectly visible. Some of the most fragile and ill-baked records that may hardly be touched without damage, have nevertheless reached us quite perfect; while others much harder have been so rubbed as to be half unintelligible. The barrels and prisms have, in many instances, been found in excellent condition, and even when broken are complete and easily mended; but most unfortunately the slabs, with the exception of the very smallest, are all broken in pieces with obvious design, so that not one is entire, and although the fragments have been carefully looked over, and all those cemented which were found to fit, yet scarcely a single specimen has been completed. Further research will probably bring to light many missing fragments, but the work cannot be trusted to those who have not made some study of the language, and these are more congenially employed in reading what is before them, than in the tedious labour of searching through heaps of dusty fragments, often finding nothing after hours of toil.

The first notices of cuneiform inscriptions, so far as the writer is cognisant, were brought to Europe by Pietro della Valle about 250 years ago; and towards the close of the 17th century, Tavernier and Kæmpfer published some imperfect specimens, which were followed by those of Chardin a few years afterwards. The first publication of a connected inscription was made by Le Brun or Bruyn, at Amsterdam in 1714; in the compartment numbered 131 of a large plate in his second volume at page 272, he gives in the three languages the inscription of Xerxes, marked C by Lassen, and 17 by Rawlinson, who has translated it at page 337 of his 'Memoir.' In 132 he has Rawlinson's No. 2, a very short inscription of Darius; but the commencing letters of each line are omitted: in 133 he gave some unconnected lines from more than one inscription, some in each of the three languages, but all imperfect; and in 134, the window inscription of Darius which had also been printed by Kæmpfer and Chardin. Most of these engravings of Le Brun may now be readily understood, although they contained many errors which would have sadly misled a decipherer. The first really good copies of the Achemænian monuments were published by Niebuhr a century ago, and these constituted the basis of all the investigations made with a view to decipherments up to the time when Colonel Rawlinson copied the great Behistun inscription, now twenty-five years ago, giving an impulse to the study of these monuments, which has resulted in such brilliant success. Niebuhr's copies were before the world half a century before any reasonable attempt was made to ascertain their tenor; and it is somewhat amusing now to run over the guesses made by really learned men: the most moderate believed they were mere ornaments carved at the caprice of the architect; one savant decided that they were charms or talismans; another read in them passages from the Koran; a third found great mysteries connected with magic and astrology. The first step made in the right direction was by Professor Grotefend, of Hanover, who collated a series of names, which there was good reason to believe to be those of the Achæmenian kings of Persia. Grotefend thus identified the names of Darius, Xerxes, and Hystaspes, and the substantives, "king" and "son;" and if he had possessed a competent knowledge of Sanscrit, he would in all probability have carried his decipherments, in a very short time, to the point which was not reached by the united efforts of Burnouf and Lassen till 1836. As an instance of sagacity defeated by want of knowledge, we may mention that the word "son," in Sanscrit *putra*, was read *bun*, because he was told told that the term *buns* was current with this meaning in India. *Buns* was the Bengalee mode of pronouncing the Sanscrit *vansa*, "a family;" the wrong application of *n* was for a long time a source of error, and it was not till 1838 and 1839, that Rawlinson and Lassen discovered the true reading of *putra*. Some twenty years after Grotefend's first step, Mons. St. Martin made an advance in reading the name of Hystaspes *Vishtaspa*, which Grotefend had made *Goshtaspa*. A more important step was made by Rask three years after, in a pamphlet printed at Copenhagen in 1826; he made known the nasals *m* and *n*, showed the accusative case ending in *n*, and the genitive plural in *anãm*; and it would seem, might have enabled a good Sanscrit scholar to read everything which the Achemænians had left behind them; but so slow was the progress made, perhaps from the little confidence felt by scholars in what had been already discovered, that nothing of value was made known for ten years after this, when Burnouf and Lassen independently published their readings of one of Niebuhr's inscriptions, pl. xxxi., containing the enumeration of the Satrapies of the Persian empire; a list of twenty-three names, which are among those given by Herodotus; this list had already in 1832 been imperfectly rendered by Grotefend. In 1838, two years subsequent to those important publications, Col. Rawlinson sent from Teheran to the Royal Asiatic Society his first communication on the inscription of Behistun, a great part of which he had copied with much difficulty and some danger. This communication, which was dated January 1, 1838, contained a transcript in Roman characters, with a translation, of the commencing paragraphs of that inscription, and every letter was read as now admitted by the common consent of all who have studied the subject. This was a promising essay, which was followed by details on the alphabet, and a précis of the contents of the inscription of Behistun. But the Affghan war compelled Col. Rawlinson to leave the scene of his peaceful labours, and nothing from him appeared in print until eight years afterwards, except very brief notices in the 'Athenæum' and 'Literary Gazette,' and in the annual 'Reports of the Royal Asiatic Society's Proceedings.'[*] At length, in the year 1846, the Royal Asiatic Society issued a volume containing the whole of the Behistun inscription, in fac-simile, together with a very complete analysis and literal translation, accompanied by copies and versions of all the Persian inscriptions which were then known to exist; to which very few additions have been made since. This volume contains also a general history of the discovery and decipherment, and a detailed memoir on the alphabet. While the work was yet printing, a letter was read from Col. Rawlinson, dated at Bagdad, August 26th, containing an additional chapter, in which the colonel communicated his discovery of inherent vowels in the letters of the alphabet, the effect of which was to bring the grammatical forms of the ancient Persian into the closest analogy with those of Zend and Sanscrit, and to remove the many anomalies attending the mode of transcription hitherto adopted. This was an important discovery for the philologist, though it added little, if anything, to the intelligence of the inscriptions; and it is a curious fact, that the same discovery was made simultaneously by the Rev. Dr. Hincks, of Killyleagh, in Ireland; a gentleman who has distinguished himself by very great acumen in all the varieties of cuneiform writing. This volume exhausted the subject of the Persian writing, and satisfied the learned that the decipherment rested on a secure foundation. The inscriptions were republished in the following year at Leipzig, by Professor Benfey, with Col. Rawlinson's versions translated into German, accompanied by a vocabulary; together with an introduction, in which the learned professor expresses himself with warm commendation of the sagacity and learning displayed by Col. Rawlinson in this valuable work. There remained now the second or Scythian kind, and the far more important Babylonian, which was to lead us to an understanding of the very ancient and not then discovered literature of Assyria.

It may be of some interest to show what is the historical result of these discoveries in the easiest and first found, but chronologically the latest cuneiform alphabet. We proceed to do it very briefly. The oldest inscription is one of Cyrus, repeated four times on the ruined pillars of Pasargadæ; it says simply, "I am Cyrus, the Achemænian." Darius has one still shorter, without the epithet, and seven of various lengths from half a dozen to sixty lines, besides the important monument of Behistun. All those of any length contain invocations to Ormuzd, and two have lists of the provinces of Persia, the latest of which in date, engraved on the tomb of Darius, included a number of names omitted in the former; probably recent annexations. Of Xerxes, the son of Darius, there are eight inscriptions, the longest having thirty lines, all of similar purport to the smaller monuments of Darius. One of Artaxerxes Mnemon was discovered at Susa after the publication of Col. Rawlinson's memoir. It contained five long lines, but it was imperfect. In this monument the king records the placing of the statues of Anaitis and Mithra in the temple of Ormuzd, and he invokes the protection of the three deities. A much longer inscription of thirty-five lines was erected by Artaxerxes Ochus, who, after the usual invocation to Ormuzd, details his pedigree up to Arshama the father of Hystaspes. It is curious that this inscription, as well as that of Mnemon, is full of gross errors of grammar, showing that the language had greatly deteriorated in the course of a century and a half, or what some may think more probable, that the language of the inscriptions was already a learned language in the earlier times of the monarchy, and that the study of it had not been kept up. The writer is inclined to believe that the old Median language had been affected by the Persian conquest; the verbal forms are not much damaged, but cases and declensions are in hopeless confusion. The difference between the styles of Darius and Artaxerxes, is as great as that found between the Anglo-Saxon of the 11th century, and the language of the century following the Norman conquest. A smaller inscription of Artaxerxes was also found at Susa, and another is in the Treasury of St. Mark, at Venice, on a vase, where it is repeated in Scythic and Babylonian, and also in regular Egyptian hieroglyphics.

The great inscription of Behistun deserves a separate notice. Its position is 300 feet from the foot of the rock, where it could not have been engraved without scaffolding; the face of the stone was carefully smoothed, and in unsound or defective places other pieces were artistically laid in, and fastened with molten lead; so nicely is this done, that according to Col. Rawlinson, "very careful scrutiny is required at present to detect the artifice." The engraving is executed in letters above an inch long, with an elegance and uniformity almost unequalled, and the whole surface was afterwards covered with a siliceous glaze of extraordinary hardness, very much of which remains on the rock, while portions that have become detached are still found in masses on the ledge at the foot.

Darius begins his inscription by tracing up his genealogy to the eponym of his family, and then enumerates the 23 provinces of his empire. He recapitulates the murder of Smerdis by his brother Cambyses, the death of Cambyses, the insurrection of Gumata (the Cometes of Justin), his death, and his own accession to the throne. We have in this the narrative of Herodotus, without the romantic stories detailed by the credulous or imaginative Greek. The first care of Darius was to restore the national worship which Gumata had neglected. While thus occupied, a revolt broke out in Susiana, and almost simultaneously another in Babylon under the conduct of a man whom Darius calls a pretender, assuming the renowned name of Nebuchadnezzar. The first revolt was easily quelled by the generals of Darius; that of Babylonia yielded only to the presence of the monarch, who after two successful battles followed the pretender to Babylon, and slew him there. While still in Babylon nine provinces took the opportunity of rising, from Assyria in the north to Egypt in the south, and even his own native Persis was one of the rebellious districts. The latter was easily quelled; but six battles were fought with very partial success against the insurgent Medes and Assyrians, who were not subdued until Darius himself took the field: he fought a battle with the Median chief, who was named Phraortes, at a place called Gundrus, and put him to flight. Phraortes escaped to Rhages, where he was captured, and brought to Darius, who cruelly tortured him, and subsequently put him to death at Ecbatana.

---

[*] See 'Athenæum,' April 14, 1838, No. 546, p. 275; Dec. 12, 1838, No. 582, p. 915; 'Literary Gazette,' Dec. 22, 1838, No. 1144, p. 809; and Asiatic Society's 'Annual Reports,' May, 1838, p. ix., and May, 1840, p. 9.

The next insurrection was in Sagartia, but the leader of the revolt, who assumed, like Phraortes, to be of the royal race of Media, was soon defeated, and put to death, after torture, at Arbela. Another revolt followed in Parthia, which was subdued by Hystaspes, the father and lieutenant of Darius, after two engagements, in the second of which he was aided by troops which his son supplied. A province of Bactria then raised the standard of rebellion, but this was quelled in one battle by Dadarses the satrap of Bactria. And now another false Smerdis arose in Persis, who gave Darius much more trouble; he made a diversion by despatching troops to Arachosia, who excited that province to revolt also. Five battles were fought, two in Persis, and three in Arachosia, in none of which Darius was present, although he appears to have been in that part of the empire. Finally the rebellion was quelled, and the chiefs were captured and put to death. In the mean time Babylon revolted again under an Armenian, who, like the former insurgent, took the name of Nebuchadnezzar, but he was defeated by the general of Darius, and crucified in Babylon.*

Here the historical part of the inscription ends, and the monument was probably erected during the period of tranquillity which ensued; but it appears from a short column subsequently added, which is very much damaged, that another revolt broke out in Susiana, which was quelled by Gobryas, the general of Darius; and again another among the Scythians on the Tigris.

The closing column of the inscription is filled with the names of the defeated rebels, whom Darius here calls kings, with asseverations of the truth of the record, a considerable amount of self-glorification, and blessings and curses invoked on the preservers and destroyers of the monument respectively; the whole concludes with the names of the six men who assisted in the death of the Magian, the false Smerdis, and a recommendation of their descendants to the monarch's successor.

We have much less to say of the second branch of the subject; historically, nothing; as the contents of the inscriptions are merely translations of those above described. The first treatise upon these inscriptions specially, by Westergaard, was published in the 'Transactions of the Northern Antiquaries of Copenhagen,' in 1845. This was a very careful analysis of all that had been then published, and considering the limited materials at his disposal, it is a monument of the learned Dane's sagacity. The memoir of Norris, published in the Royal Asiatic Society's Journal, in 1853, had the advantage of a greatly increased quantity of material, Sir Henry Rawlinson having placed at the writer's disposal the paper casts of the great inscription of Behistun, which enabled him to show the value of many characters not ascertained previously: out of 105 characters he found the approximate sound of 84, and in most of these he agrees with Westergaard. In regard to the language, Norris's opinion was, that it belongs to the Turanian division; and he was inclined to look upon it as more like the Ugrian branch than any other, although agreeing here and there in its vocables rather with Mongol or Turk. The Turanian division of languages includes a very large number of tongues, with far greater differences than those found in the Indo-Germanic or Semitic families in their largest extent, and any features in which all agree are rather negative than positive. Norris suggests, in p. 52, that the cuneiform system was invented by a Scythic nation, which seems to be confirmed by the discovery of the præ-Semitic inscriptions of Nineveh, and by the investigations of Oppert. He also gives some reasons, in p. 205, for a supposition that the natives of the province of Persis were Scyths; possibly they spoke the language of the inscriptions of the second kind, which may have been adopted by Cyrus in preference to the dialects of the other barbarous tribes of the empire, because it was that of his native province. Norris suggested that the dialect was that of Susiana, but nearly all the inscriptions found in Susa are in a different though probably allied language.

The value of this part of the investigation is merely philological; unless it may by-and-bye afford a clue to the other languages which we find written in cuneiform characters, and it may even aid in deciphering the præ-Semitic Turanian tablets, which reach to 2000 B.C.

We now come to the Assyrian or Babylonian inscriptions, a branch of the inquiry quite unnoticed when the subject was first studied, but which now, from the great number of relics found, and their far more ancient date, extending to a period when all profane history is silent, has arrived at dimensions that have thrown all the rest into the shade. The brilliant results of the researches in and about Nineveh have been already mentioned, and we have spoken of the very large numbers of earthen blocks and slabs brought home, the principal vehicle for the literary labours of the Assyrians, nothing having been found in any way resembling parchment or paper. There is no doubt, however, that something of the sort existed; perhaps leather skins; we find in several bas-reliefs now in the British Museum, which represent the enumeration of things required to be numbered, such as the cattle passing through the gate of a city, or the more favourite occupation of counting a heap of heads cut off from the king's enemies,—two men pictured with writing materials in their hands, one of them having a little slab with a pointed tool digging into its surface, and the other usually provided with a flexible roll, the end hanging loosely down, upon which he is obviously writing with ink—no doubt checking his companion. The contemporary records of the Bible show the same usage. Isaiah, viii. 1, mentions a roll for writing; and in xxxiv. 4, the rolling of a book is alluded to. Of the etymology of these words, from a verb signifying *to roll*, there is no doubt; about the ink of Jeremiah (xxxvi. 18), and the inkhorn of Ezekiel (ix. 2), there is less certainty, although the usual acceptation of the words is probably the right one.

The decipherment of the third class of cuneiform inscriptions is due mainly to the sagacity of Sir Henry Rawlinson, though much has been done by Dr. Hincks and Mons. Oppert. Sir Henry was favourably placed at Bagdad for making himself acquainted with the inscriptions found by Layard, which passed through his hands on their way to England; he had a critical knowledge of the Arabic language, and he was not unacquainted with the other Semitic tongues. As soon as he saw the value of the new discoveries which Layard and Botta were copiously bringing to light, he quitted the study of the first branches of the investigation, now almost exhausted, and plunged eagerly into the new mine. In spite of all the difficulties attending the clumsy and enigmatical Assyrian mode of writing, which can hardly be called an alphabet, he made rapid way, aided by the unfortunately much-damaged version of the Behistun inscription in the Babylonian language and character, which were sufficiently like the Assyrian to enable a philologer to make his first steps with confidence. Into the details of the decipherment this is not the place to enter. Colonel Rawlinson's memoir, containing his analysis of a considerable portion of the great Babylonian inscription, was printed in 1851 by the Royal Asiatic Society. This still awaits completion; but enough is given there to enable a man with a good knowledge of Semitic languages, Hebrew especially, to read many passages in any historical monument. It has already in this country enabled Mr. Fox Talbot to translate nearly the whole of the annals of Tiglath Pileser I., and some portions of the hieratic slab of Nebuchadnezzar which was presented to the East India Company in the beginning of this century. The frequent admixture of the forms and words of the ancient race who preceded the Assyrians in the lands watered by the Tigris and Euphrates, the probable inventors of this mode of writing, concur with the clumsy adaptation of the alphabet to puzzle the most learned and energetic investigator in many places. The number of vocabularies found in the ruins of palaces, upon which the ancient Turanian words are explained in ordinary Assyrian, shows that the difficulty was felt twenty-six or twenty-seven centuries ago, when the language was vernacular: we may expect to find it greater now. The difficulties are gradually diminishing, but much remains to be done; and the very fragmentary condition of the vocabularies found will perhaps render a complete knowledge of Assyrian impossible. But we do not despair; the first part of the 'Corpus Inscriptionum,' compiled by Sir Henry Rawlinson, and printed at the cost of government, is already completed, comprising 70 large sheets of monuments, chiefly historical, beginning with the stamped bricks of the ancient Turanian monarchs of twenty centuries before the Christian era, and proceeding downwards to the annals of the successors of Nebuchadnezzar. A second part is in preparation, which will contain vocabularies, mathematical tables, astronomical observations and calendars, mythological tablets, lists of dynasties, descriptions of countries, rivers, and mountains, classified lists of animals, and a great variety of miscellaneous matter. When the united efforts of some dozen patient and energetic learned men shall be brought to bear upon this mass of material, we may hope that every thing will be discovered which is not really impossible.

A good many Assyrian inscriptions have been found in the hieratic character, which diverges from the ordinary form much in the same way that the various monkish forms called Gothic, Old English, &c., differ from the Roman type. These would have formed a more serious difficulty but for the discovery of a fragment, now in the British Museum, which was very accurately engraved and published by Ker Porter. This proved to be, so far as it went, a copy in cursive character of the great inscription of Nebuchadnezzar, engraved in the complex hieratic character. Three of the inscriptions in the volume mentioned above, prepared by Sir Henry C. Rawlinson, are in this character.

---

* It is curious that, after mentioning a battle, the Babylonian version always records the numbers of the killed and taken; a particular neglected by the less mathematical Medes and Persians. The love of calculation was certainly active in the Babylonians, and was more beneficially directed in their astronomical labours.

The inscriptions of Van in Armenia, copied by Schultz, and published by the Asiatic Society of Paris, have not yet been read. A fair commencement was made by Dr. Hincks in the ninth volume of the Royal Asiatic Society's Journal, 1848. Dr. Hincks gave some strong reasons for considering the language to be of the Indo-Germanic family; but we are not aware that he has followed up his investigations.

The incriptions of Susa appear to be in a Turanian language; but they have not yet been seriously investigated, and, in fact, they are too few to afford much scope to a decipherer. Several of the words appear to be identical with those of the inscriptions of the second class; but the alphabet is on the whole more complex than that of the Assyrian class.

The language of the predecessors of the Assyrians, who appear to have been named Accadi, will form a more serious study; the considerable number of slabs in their language now in the British Museum, and the continued influence of that language upon, or at least admixture with, the Assyrian of all the monuments, will by-and-bye excite more attention than it has yet met with. A small grammatical tablet, on which the Accad forms are compared with the Assyrian, was copied by Mons. Oppert, who has also published in Paris a valuable historical sketch of the history of cuneiform decipherment.

A few remarks may be allowed on the reality of cuneiform decipherment, as doubts have often been expressed in relation to this reality. It has been vehemently disputed by some persons of note, though we are not aware of the grounds of their objections. We have heard of two arguments only, and they are mutually destructive; the one is that no decipherment is trustworthy that does not concur with some independent testimony; the other that independent testimony renders the result suspicious, because a decipherer would, even unconsciously, suit his readings to such testimony: as in the case of the genealogy of Darius, where the Behistun monument agrees with Herodotus. With regard to the Persian inscriptions, written in a limited alphabet, with words clearly separated, a denial of the possibility of decipherment would be tantamount to denying that any writing in unknown characters could ever be deciphered; a feat easily accomplished by a clever schoolboy in his own tongue, while the circumstance that a decipherer works upon a language not his own could do no more than make the task difficult, provided that the language to be read was one that the decipherer knew something of. It would puzzle a man to contrive a false alphabet which would make sense of a short English inscription of a dozen words only, and the credulity must be very ample indeed that could swallow such a contrivance in the case of an inscription of five hundred lines. There would be more reason to doubt of the reality of Assyrian decipherments, because of the complicated mode of writing used, if we had not at our disposal a pretty long bilingual (in fact trilingual) inscription, in which one of the languages is Assyrian, and another read partially at least. This inscription contains a large number of names, and thus it gave us many letters of our new alphabet. A reasonable objection brought forward to the reading of these monuments lies in the alleged existence of polyphones, or characters having several powers. No doubt some difficulty arose from this, but it has been overrated; we have something like it in our own *c* and *g*, which letters have two sounds each. But, strictly speaking, we believe there are few, if any, polyphones; each letter has one sound, though some have several significations. An analogy with this may be see in our letter *x*, which has one sound but several values. Most Englishmen seeing Xber, Xtmas, Charing X, Charles X., will at once read December, Christmas, Charing Cross, and Charles the Tenth, but they would hardly say that *x* had five phonetic powers. The Assyrians had several such characters, but their use was limited, though the reader must have been occasionally in doubt. But reading is a difficult task in most Oriental nations, and the accomplishment could hardly have been universal in Assyria, nor would written works be so numerous as to demand much rapidity in reading. If many books existed, we are inclined to believe that they were written on skins or leaves, in some less cumbrous writing than that of the monuments which have survived the lapse of so many centuries; and traces of such writing appear here and there on the Assyrian bricks, not yet read, but having some resemblance to Phenician.

On the whole we do not hesitate to express our conviction that the decipherers of Assyrian are on the right path, and that simple narrative passages are now read with tolerable accuracy; but it will require the united efforts of many scholars, and the compilation of a dictionary, in which the varying forms constituting the power and the difficulty of Semitic languages shall be brought under their respective roots, and their values thus specified, before the long lost monuments now so happily discovered shall be completely understood.

CUPEL; CUPELLATION. [Assaying.]

CUPID. [Eros.]

CUPOLA. [Dome.]

CUPPING is of two kinds: one by which some blood is taken away, generally simply termed cupping; the other when no blood is abstracted, which is accordingly termed dry cupping. The preliminary steps of the operation are the same in both cases: the part to which it is intended to apply the cupping-glasses is washed with warm water, or a warm cloth is merely applied to it, in order to attract blood to the part. A small bell-shaped glass, a portion of the air of which has been expelled by holding it for an instant over the flame of a spirit-lamp, is immediately applied to the spot which has been prepared. The usual amount of pressure on the part being diminished, the blood flows to the part, and produces distension of the vessels and elevation of the surface, as well as a purple or livid colour. If it be intended to take away blood, the cupping-glass is speedily removed, and an instrument called a scarificator, containing a number of lancets, sometimes as many as twenty, is applied, and made to act so as to inflict a corresponding number of incisions on the skin and subjacent vessels. "The instrument is so constructed, that the depth to which the lancets penetrate may be made greater or less at the option of the practitioner." It is not in general advisable that the depth should be very great, as more blood flows, and the vessels will continue to bleed longer, if only partially divided, than if completely cut through. The cupping-glass, exhausted as before, is to be immediately replaced, and if skilfully applied, and the air has not been too much rarefied, by which too great pressure is made by the edges of the glass, a considerable quantity of blood will flow into it. When nearly full, or if the blood begin to coagulate, the glass is to be carefully removed, the wounded part quickly washed with a sponge with warm water, and the glass having been emptied and washed, is to be again applied, if a sufficient quantity of blood should not have been obtained by the first application. Two or more glasses may be applied to different spots at the same time, so that the quantity of blood desired, or necessary to obtain the object in view, may be more quickly abstracted.

"Where dry cupping only is intended, the glasses may be permitted to remain on the skin for a few moments, and replaced five or six times, with a little variation of their position, in order to prevent the skin from being hurt by their pressure."

Cupping by which blood is abstracted is used either where general bleeding is unnecessary, or as supplementary to it, for the removal of congestions or local affections. It is analogous to the use of leeches, over which, however, when the situation of the part admits of the application of the glasses, it has in general many advantages. The blood is more rapidly abstracted, a point of great importance in inflammatory diseases; there is less risk of subsequent bleeding from the wounds; and the part of the body subjected to the operation is exposed to the air for a much shorter time. Cupping is also preferable in cases where the application of leeches is apt to be followed by severe erysipelas of the skin.

"In inflammations and congestions about the head, cupping on the back of the neck and between the shoulders is a most useful mode of abstracting blood; and this operation is also particularly applicable for the removal of blood from the parietes of the chest and abdomen in diseases of the different viscera. Its use, however, is only admissible when it can be employed without exciting pain, and irritating the diseased organ." Many cases of impending apoplexy may be warded off by the timely application of cupping-glasses to the neck, aided by a quickly-acting cathartic. Where the abstraction of blood is inexpedient or unnnecessary, dry cupping is often resorted to with benefit. In adynamic states of fever, especially where the lungs are complicated in the diseased action, if "farther depletion cannot be ventured upon, dry cupping on the back or chest will sometimes be serviceable." (Copland's 'Dictionary of Medicine,' p. 930.) Dry cupping often affords great and immediate relief in many pains of the side, not inflammatory, but hysterical, which occur in females. The pains of the back which likewise occur in females at particular times may be much mitigated by dry cupping. The pains in the chest in consumptive patients are often quickly relieved by dry cupping,

Another and most important application of cupping is the prevention by its means of the absorption of poisonous fluids from wounds. For this purpose, anything by which a partial vacuum over the wounded part can be produced will answer, such as a wine-glass, tumbler, or teacup with a smooth margin, from which the air has been partially expelled by holding it for a moment over a lighted candle. This mode was in use among the ancients, has been revived among the moderns, and is practised by the South Americans in cases of the bites of venomous serpents, by means of a funnel-shaped calabash. The Greeks called a cupping instrument *σικύα* (sikua), from its bearing some resemblance to the form of a melon or gourd.

(Empson's *Narratives of South America*, p. 66; Wardrop *on Blood-letting;* Cooper's *Surgical Dictionary*.)

CURARA. [Curarine.]

CURARINE. An alkaloid of unknown composition found in *curara*, the poisonous extract of the plant called *mavacure*, used by the South American Indians for poisoning their arrows. Curarine is obtained from curara by a tedious process which need not be here detailed. It presents the appearance of a yellow horny deliquescent mass, having a very bitter taste. It appears to form neutral salts with acids, but all those known are uncrystallisable. The most remarkable property of the curara, from which it is extracted, is that it may be taken into the alimentary canal of man or of animals with impunity, whilst a very small quantity introduced beneath the skin, rapidly produces fatal results.

CURATOR (from *curare*; that is, "to care," or "take care"), one who is appointed to take care of anything: in this general sense there were many kinds of curators.

In the civil law the word denotes one who is appointed to administer the estate of any person who is not legally competent to manage his property. 1. There was the curatorship (that is, guardianship) of minors (*cura minorum*). Every person who was *sui juris* (that is, not subject to paternal or domestic dominion, but who was still under age) was put under the superintendence of a guardian. But the Roman law distinguishes two kinds of guardianship; namely, tutelage (*tutela*) and curatorship (*curatela*). (Institutes of Justinian, i. 13.) The former kind of guardianship was in use if the minor was impubes; that is, if a male minor was not fourteen and a female not twelve years old. The guardian in this case was called tutor, and the minor, pupillus. After the tutelage was ended, in order to give some legal protection to those who, owing to youth and inexperience, might be overreached, without interfering with the old principle of full legal capacity being attained at the age of puberty, a law (Lex Plætoria) of uncertain date was passed, dividing citizens into two classes, those above and those below twenty-five years of age, for the purpose of protecting minors against fraud, by enabling them to receive curators till they attained twenty-five years. This distinction had some important consequences in the civil law, which have only recently fallen into disuse even in countries where the Roman law is still in force,—a distinction which Savigny has seized with his practised eye and explained with his usual clearness and ability. The maxim of the Romans, "personæ non rei vel causæ tutor datur" (D. 26, 26, 14), is the key to the whole system of Roman tutelage. The persona is the legal personal capacity of the ward, his capacity for formal transactions. The tutor's principal duty was to render this capacity complete (which is the meaning of the passage), and therefore his functions extended necessarily over the whole property of the ward, whose incapacity to contract or to enter into any kind of business was supplied by the tutor's direct personal intervention (auctoritas). The distinctive and important function of the Roman tutor, therefore, was to do what the ward could not legally do for himself, and what a *mere representative* could not do for him; namely, transact mancipations, stipulations, and other such forms. Hence we obtain the precise difference between the tutor and the curator,—that the former was the legal alter ego of the pupil or minor; the latter the mere representative of the ward, the ordinary administrator of his rights; and, therefore, in the maxim "per extraneam personam nihil adquiri (ne que alienari) posse," I. 2. 9. 5. the difference between the tutor and the curator is distinctly aimed at. (See 'The Vocation of our Age for Legislation,' by Von Savigny, trans. by A. Hayward,' p. 121.) According to the strictness of law, the curatorship terminated with the twenty-fifth year of the minor; but it could also be determined by a solemn declaration of the emperor that the minor should be of age. (C. 2, tit. 45, de iis qui veniam ætatis.) This was called receiving veniam ætatis, and it could take place in the case of males in their twentieth, and females in their eighteenth year. 2. As spendthrifts and deaf and dumb persons could not legally administer their estates, they also were put under the superintendence of a curator. 3. A third kind of curator was the curator bonorum; that is, a trustee for the administration of the estate of absent or deceased persons and insolvent debtors. Between this curatorship and that of a minor there was this important difference; the latter was regarded as a public office, which could not be refused, except for such reasons as the law allowed; whilst between tutela and curatela this distinction deserves notice, that the duties of the tutor related to the person of the pupil, those of the curator to the property.

(Gaius, i. §§ 197-200; Just., 1, 23-26; D. 26, 3-10, and 27; and 5, 31-75; 'Ulp. Frag.,' tit. 11 & 12; 'Warnkönig Institutiones,' lib. i. ch. 4, §§ 238-265; 'Muhlenbruch Doctrina Pandectarum,' vol. iii., ch. 3, §§ 576-608; and 'Dictionary of Greek and Roman Antiquities,' article 'Curator.')

Curators in ancient Rome were also public officers of various kinds, particularly after the time of Augustus, who established several officers with this title. (Suet., 'Vit. Aug.,' cap. 37.) 1. Curatores viarum; that is, curators who superintended the laying out and repairing of the public roads. This office existed under the republic, but it was only held as an extraordinary one, and was conferred for special purposes. 2. Curatores operum publicorum, aquarum, cloacarum, who had the superintendence of the public buildings, theatres, bridges, aqueducts, and cloacæ. 3. Curatores alvei Tiberis, who were the conservators of the Tiber. 4. Curatores frumenti populo dividundi, whose duty was to distribute corn among the people. Under the emperors we find other officers with the name of curatores; as, for instance, the curatores ludorum, who had the superintendence of the public amusements; and curatores reipublicæ, also called logistæ, whose duty it was to administer the landed property of municipia.

CURCUMA LONGA, *Medical Properties of.* This perennial plant, belonging to the tribe *Zingiberaceæ*, is not ascertained to be native of any particular country in the East; it is occasionally wild, and it is also extensively cultivated in China, Java, Malacca, and in Bengal, prospering in a moist but not swampy soil. The mode of culture is described under CURCUMA, in NAT. HIST. DIV. The Chinese sort is most esteemed, rather on account of its superior richness in colouring matter than from any other cause. Two varieties are found in commerce, the round turmeric (*Curcuma rotunda*) and long turmeric (*C. longa*). These are generally regarded as the produce of the same plant; but even were they yielded by two, it is altogether incorrect to assign the round to *Curcuma rotunda*, Linn., which is the *Kæmpferia ovata*, Roscoe, a rare plant, the root of which is destitute of any colouring principle. The name is derived from the Persian kurkum, which means saffron; hence it is termed Saffran des Indes, but must not be confounded with common saffron, from *Crocus sativus*. It is likewise called by the French *Terra merita* (Curcuma, hæc Gallis Terra merita male dicitur), see Royle, 'Antiquity of Hindoo Medicine,' p. 37. The rhizoma or rootstock alone contains the aromatic and colouring principles, as the tubers common in this and other scitamineous plants, are devoid of both, and yield much of the East Indian arrow-root, being one of the kinds called by the natives Tikor. *Curcuma zedoaria*, Roxb., yields zedoary, which resembles turmeric.

Round turmeric occurs in knobs, roundish, ovate, or oval, sometimes pointed, and insensibly running into the long turmeric, and is of a deeper, more camboge like colour in the interior. The pieces are from one to two inches long, and nearly one in diameter. The long turmeric occurs in pieces about two inches long, either straight, or curved, and doubled up, presenting on the surface more marks whence the root-fibres have sprung. The colour externally is of a brownish yellow, internally lighter than that of the round sort. The fracture has a waxy appearance, and the odour is unctuous. The taste is bitterish, aromatic, and like ginger, but less potent. "In the fresh state it has a rather unpleasant smell, somewhat resembling cerate, which goes off a good deal on drying."—Ainslie's 'Mat. Indica.' This article is very liable to be eaten by small beetles. Old, worm-eaten specimens should be rejected. Hard compact pieces, which with difficulty can be powdered, are best. It has been analysed by John, and subsequently by Vogel and Pelletier:—

John's Analysis.		Vogel and Pelletier's.
Yellow volatile oil	1	Acrid volatile oil.
Curcumin	10 to 11	Curcumin.
Yellow extractive	11 to 12	Brown colouring matter.

but curcumin in a pure state can only be obtained by digesting the alcoholic extract of turmeric in ether, and evaporating the etherial tincture to dryness. Its appearance in the mass is brownish-yellow, but when powdered, a full yellow. It is tasteless, odourless, almost insoluble in water, but readily soluble in alcohol and ether. The alkalies colour it a reddish-brown, and readily dissolve it. The alcoholic solution evaporated with boracic acid becomes red. Hydrochloric acid also reddens it. The alcoholic solution of curcumin produces coloured precipitates, with several salts, such as acetate of lead and nitrate of silver (Pereira). The frequent use of turmeric as a test renders a knowledge of these points necessary. (See Fresenius, 'Chemical Analysis,' by Bullock, p. 31.)

Turmeric has aromatic qualities which render it useful in languid habits, where digestion is difficult, and the circulation slow. The repute it enjoyed as a cure for jaundice and dropsies was founded on the doctrine of signatures (Cullen, 'Mat. Med.,' i. p. 25). It is of some importance as a dye, but it is as a condiment, both in the East and in this country, that it merits notice, as it is an ingredient in all curry powders and *curry pastes*. When in excess the colour is too brown, and one flavour predominates, which is contrary to sound apician law. The same observation applies to Cayenne pepper. "With us, turmeric and Cayenne pepper prevail in them far too powerfully."—Acton's 'Modern Cookery,' p. 227. The preceding table, extracted from the 'Pharmaceutical Journal,' vol. iv. p. 364, supplies an infinite variety of receipts for preparing curry powder, But whichever is preferred should have added to it some *mushroom-powder*. The meat, fish, or whatever article is employed as the basis of the curry should always be so perfectly boiled that it can be eaten with a spoon. This necessarily destroys the natural flavour of the meat. The mushroom-powder contains *osmazome*, the source of flavour in meat, and consequently it restores what the long cooking has dissipated. The curry-powder should not be added to the dish till a few minutes before it is to be served to table.

In the East, ready mixed ingredients are carried about from place to place, forming extensive articles of commerce, under the name of curry-stuff. These differ, according to the localities and taste of the natives; but whatever be the basis of a curry, the superiority of Indian to European curries, is the addition of *fresh acid vegetables*. It was a great error therefore in M. Soyer, in his 'Modern Housewife' to enjoin sugar as an ingredient. The Ceylon curry-stuff consists of "a piece of green ginger, two cloves of garlic, a few coriander and cummin fruits (seeds commonly), six small onions, one dry chili or capsicum, six or eight corns of pepper, a small piece of turmeric, half a dessert spoonful of butter, half a cocoa-nut, and half a lime." Simmonds', 'Dictionary of Trade Products.'

CURCUMIN. A resinous colouring matter found in turmeric-root. The root is first exhausted with boiling water: boiling alcohol then dissolves curcumin from the residue. It may be further purified by solution in ether.

Curcumin is amorphous, nearly insoluble in water, but very soluble in alcohol and ether. It is bleached by exposure to the sun's rays. It readily dissolves in alkalies with a deep red-brown colour. Hence the use of papers imbued with turmeric (turmeric papers) for the detection of an alkaline re-action. Curcumin consists of

CURDS AND WHEY. [CASEIN.]

CURFEW. The custom of covering up their fires about sun-set in summer, and about eight or nine at night in winter, at the ringing of bell called the *couvre feu*, or curfew bell, is supposed to have been introduced by William I., and to have been imposed upon the English, as a badge of servitude. But the custom appears to have prevailed throughout Europe prior to this period; and was intended as a precaution against fires, which were then very frequent and destructive, so many houses being built of wood. Henry I. appears to have restored the use of lamps and candles at court in the night after the ringing of the curfew bell, which had been prohibited by his predecessors. (Will. Malmesb. fol. 88.)

Although spoken of by modern writers as a tyrannical custom, we find the curfew mentioned to a late period as a common and approved regulation. Among the charges directed for the wardmote inquests in London, in the mayoralty of Sir Henry Colet, in 1495, it is said, "Also yf there be anye paryshe clerke that ryngeth curfewe after the curfewe be ronge at Bowe Chyrche, or St. Bryde's Church, or St. Gyles-without-Cripelgate, all such to be presented." (Knight's 'Life of Dean Colet.') The same charge remained in the wardmote inquest, as printed in 1649. Hutchins, in his 'History of Dorsetshire,' vol. ii., speaking of Mapouder church, in that county, mentions land given "to find a man to ring the morning and curfew bell throughout the year." In the same volume, under Ibberton, is mentioned an acre given for ringing the eight o'clock bell, and 4*l.* for ringing the morning bell. At Barking, in Essex, the tower of the fire-bell or curfew still stands, and bears the name, though no longer used for its pristine purpose. Bishop Hall, in his 'Virgidemiarum,' printed in 1599 (b. iii. sat. 4), speaks of the gift of a new rope to ring the curfew bell as of occasional occurrence in his time:—

> "Whoever gives a paire of velvet shoes
> To the Holy Rood, or liberally allowes
> But a new rope to ring the curfew bell,
> But he desires that his great deed may dwell,
> Or graven in the chancel window glasse,
> Or in the lasting tombe of plated brass."

The curfew bell, strictly as such, had probably fallen into disuse previous to the time of Shakspere, who in 'Romeo and Juliet' applies the term to the morning bell:—

> "The second cock hath crow'd,
> The curfew bell has rung, 'tis three o'clock."

In the 'Antiquarian Repertory,' old edit., vol. i., is an engraving of an iron implement which is called a curfew, or cover-fire, formerly belonging to Gostling, the historian of Canterbury, and presumed to be of very ancient if not of Norman origin, but which in reality is no more than an *ex tempore* oven, lately if not still used in many parts of England for baking small viands: the hearth is first heated, the viand placed upon it, and then covered with this implement, the embers being raked round and above it. The practice of ringing the church bell at eight o'clock in the evening is still continued in many parts of England; and in many places where it is no longer rung, it has only been discontinued within memory.

CURIA. [COMITIA.]

CURRANTS. The fruit of the various species of *Ribes* (for the botanical account of which, see RIBES, in NAT. HIST. DIV.) has been used in medicine to allay thirst, and it is said to lessen the secretion of bile. The juice of the red currant is sometimes employed in making punch, and mixed with water forms the *eau de groseilles* of the French. It is also made into a jelly, and the berries are used for making tarts and puddings. When ripe the fruit makes an excellent wine, which is much used in the rural districts of England. The juice of the black currant is even more generally employed for making jelly, and the fruit is likewise used for tarts and puddings, and wine.

All the sorts are hardy plants, growing freely and bearing a plentiful crop of fruit. They thrive almost as well in one situation as another, whether it be open or shady, free or confined. This permits of the ripening of the fruit throughout a long period, so that it may be obtained as early as June and as late as October. Common garden soil is suited to them, which should be tilled and recruited from time to time with fresh manure. The largest crops are produced in a strong loam or improved clay soil. They are earlier in a light soil. Previous to planting, the soil should be dug two feet deep, and this may be done at any time from October to February or March. They are chiefly propagated by cuttings obtained early in the spring. These should consist of the previous year's shoots taken from bearing-branches, and be from ten inches to a foot in length. They should be planted 4 or 5 inches deep and may be watered in spring. In the summer all the shoots or buds should be removed except three. In the following autumn they may be transplanted. Currant bushes are best planted by themselves, and the distance between the rows should not be less than from 7 to 9 feet. They will grow freely against a wall, and when thus planted with a south or south-west aspect will produce ripe fruit three weeks earlier than standards with a north or north-east aspect: fruit may be preserved good till October, and if matted, as late as November. Grown on espalier rails the fruit is produced in the finest order.

The fruit of the currant should be gathered in dry weather, as when gathered in rain it loses its flavour.

CURRENCY. In this article it is proposed to present some of the fundamental principles of this great subject, a full inquiry into which is beyond the scope and objects of our undertaking. The term currency is used to express the circulating medium of exchange, by means of which sales and purchases are effected without the necessity of a recourse to barter. Various contrivances have been adopted at different periods of the civilisation of nations for this purpose: stamped pieces of leather passed as money among the ancient Lacedæmonians *corium formâ publicâ percussum* (Seneca, 'De Benef.' lib. v. cap. 14) and Carthaginians. Salt in lumps was used as money among the Abyssinians (Smith, 'Wealth of Nat.' b. i. cap. 4). The shells called cowries constitute the received currency in parts of Hindostan and the interior of Africa. When the Spaniards first visited Mexico, the natives, it is said, used cocoa nuts as the medium of exchange. Tobacco made up in bars or rolls, in Virginia and some other states of North America, in the early periods of their settlement, were made legal tender by law (Tatham 'Histor. Essay on Tobacco'). But there are obvious objections to each of these or similar materials of a currency, either from bulk, weight, want of invariability of value, want of durability, or some other requisite to a convenient medium of circulation. These reasons have driven all civilised nations to the employment of gold and silver, coined into pieces of different values, as the basis of their current money. [BULLION.] But as population increases, and the wants of men multiply, and the movement of commerce becomes more rapid and oftener repeated, the quantity of gold and silver money requisite for carrying on the increasing number of the operations of trade and business increases, and the cost of such a currency becomes enormously magnified · and hence arises a difficulty which has given birth to one of the most refined of all the expedients for facilitating intercourse which the necessities of society have generated. Paper money is the result: whereby in the larger transactions of business an acknowledgment of a debt or a promise to pay, expressed in writing, by an individual or body of individuals, passes from hand to hand as money, the circulation of such paper depending, in the first instance, on the credit of the person who acknowledges his liability or pledges his promise, and subsequently on the credit, in addition, of those who successively receive and pay the instrument as though it were really worth so much money as it purports to be worth. By this means, therefore, a large addition may be made to the circulating medium of a country, at a small expense, as compared to the expense of providing the same amount of metallic money. In fact, a paper currency substitutes credit for coin. In France, the currency is wholly metallic, consisting of gold, silver, and copper. Their gold and silver currency has been estimated as of the value of 2200 to 2500 millions of francs: the maintaining of which (supposing the usual rate of profit to be 6 per cent. per annum, or that the money, if not employed in the coinage but employed in business, would have, in ordinary times, fetched that profit) would yearly cost the public exchequer 132 millions of francs, without calculating wear and tear and loss. With these and other additional expenses depending on casualties, it may fairly be inferred that the cost, to the nation, of the gold and silver portion of the currency of France is not much less than six million pounds sterling a year. In this country, the national currency is partly metallic and partly of paper; the latter being divisible into inconvertible paper money and convertible paper money. The former consists of the bank-notes of the Bank of England, which practically may be said to circulate as money *per se*, because they constitute a legal tender, that is, they must be accepted in payment of debts, and payment in gold or silver is only demandable for them at the Bank of England or its branches. [Banking.] The convertible paper money consists of the bank-notes of private bankers and banking copartnerships, which are payable in gold or Bank of England notes on demand at the respective banks. These a creditor cannot be obliged to receive in payment of a debt due to him. The peril of an inconvertible paper currency is, lest those in whose hands is the power of issuing it should be tempted to overdo the quantity of paper sent into circulation, a proceeding the results of which are most disastrous. An instance will show this: Suppose Jones gives Thompson his bill of exchange for 360*l.* at 3 months, in payment for 120 quarters of wheat at 3*l.* a quarter, and at the end of three months pays Thompson 360*l.* in bank-notes. But suppose that, in consequence of an over issue of bank paper beyond what is duly required for the necessary circulation, wheat in the meantime has risen to 4*l.* a quarter; then Thompson can only buy 90 quarters with his 360*l.*, and is in the same condition as if he had in the course of the three months lost or been robbed of 30 quarters. This shows why uniformity is one qualification of a proper currency, in fact an essential; it shows how those who sell on credit must be prejudiced if, between the date of the contract and the day on which the credit expires, the price is altered by a fluctuation in the medium of exchange. The landlord is also in the same position, though in this case the result is not susceptible of being shown with the same clearness: but in this case also, increased abundance of money taking place between the date at which the terms of a lease are settled, and the expiration of it, are prejudicial to him and favourable to the tenant: on the other hand, a diminution in the circulating medium has in general a tendency to produce a fall of prices. One of the great problems of the currency in this country is, "What is an issue of currency in excess?" It has commonly been granted that the payment by Government of the sums, owing by them on account of the state, in inconvertible bank paper may cause an over issue, so that the value of such paper may become depreciated by such excess. The case of the *assignats* in France, in the time of the Republic, is in point. They were practically inconvertible, they were over-issued, and became vastly depreciated. But whether the bank-notes which are issued by the Bank of England, in the discount of bills of exchange presented to them in the course of business, can be issued in excess, so as to be depreciated, has been much contested. These issues, it is urged, are nothing but a compliance with the legitimate demands of the public for circulating medium; the supply of notes in such case is necessarily exactly limited by the demand, and by the amount of security which can be provided by those who require the accommodation: and therefore, it is said, there can be no excess, and so no depreciation. In truth, however, there is no tangible limit to the public demand for ready money, and therefore the above considerations have not been deemed in general to be conclusive, nor do the best authorities consider that there is any difference, in respect of over-issue and depreciation, between the two modes of adding to the currency above mentioned. What then is the result of any over-issue of paper money in this country, so that the whole currency becomes larger than the wants of trade or the necessity of an adequate medium of exchange require? The over-issue is corrected in this way: As soon as the over-issue depreciates the whole currency by more than 1, or from 1 to 2 per cent., then as gold is everywhere in demand, and the expense of the transmission of it seldom exceeds from 1 to 2 per cent., the foreign exchanges will become unfavourable to this country, and gold will begin to be worth exporting, and will be exported, and the issuers of paper must withdraw their superfluous issue as quickly as they can, in order to restore the equilibrium of the currency. That over-issues may depreciate the currency, at least the paper portion of it, is manifest from the circumstance that in 1814 bank paper was at a discount as compared with gold of not less than 25 per cent. So a metallic currency may be depreciated by wear and tear. Thus, previously to the great recoinage of the silver currency under Mr. Montague, then chancellor of the exchequer, in the reign of William III. (begun in 1696), the silver in circulation was so much worn, &c., that the golden guinea passed current at from 28*s.* to 30*s.* (Earl of Liverpool on Coins.)

It will be observed that amongst the various descriptions of paper currency we have not included bills of exchange, cheques, and promissory notes of merchants, &c., an immense value of which is constantly passing from hand to hand, and operating in some respects as money; and the reason why these kinds of paper are not included is that there are substantial and material differences between these and the former characters of paper, such as the following: a bank note purports to be payable on demand; passes by delivery without indorsement, the party receiving it has practically and in general no claim on the party from whom he received it as payment. (See Grant, on 'Banking,' pp. 408-412.) Bills of exchange, &c., are mostly drawn payable at a day to come; every one whose hands the bill passes through must indorse it if he wishes to pay it away, and by so doing makes himself liable in respect of it for the ultimate payment of the sum mentioned in it. The circulation of a bill depends chiefly on the confidence felt by the receiver of it in the last indorser, his own correspondent in trade. The circulation of a bank note is due rather to the circumstance of the character and responsibility of the party issuing the note being well known to the receiver, or being a person or house of generally established credit. In this country the law as well as the practice and opinion of merchants and political economists make the same distinction. (Chitty on 'Bills,' pp. 1, 2, 3.) It is observable also that bills of exchange no where form the circulation of any place or district, though they may each for the time it has to run, and for the amount it stands for, have circulated amongst the persons whose names appear upon the back of it as indorsers, generally but a small number of persons; therefore bills of exchange and promissory notes of merchants, do not seem to be money, and are not usually (though some authorities are of a different opinion) considered as forming parts of the currency. Some persons hold that not only bills of exchange and promissory notes, but cheques and drafts on bankers, and even money deposited with bankers, are to be considered as part of the currency; but the grounds on which this theory is attempted to be supported, have met with but little adherence. ('Evid. before Committee of H. of Com. on Bank Acts of 1858,' Q. 932, 933.)

The average circulation of Bank of England notes required for the purposes of business in England and Wales—in Scotland Bank of England notes pass but to an exceedingly limited extent—is from 19,000,000*l.* to 20,000,000*l.* This amount varies at different times; it has been as high as 23,000,000*l.*, and as low as 17,000,000*l.* ('Evidence before Committee of H. of Com. on Bank Acts of 1858,' Q. 657, 660, 674, 677, 947, 950.) Yet the proportion is small which the Bank of England notes perform in the function of circulation, and the liquidation of debts and payments throughout the country. (*Idem.* Q. 2411, 2414, 2394, 2771.)

There has been a remarkable variation in the quantity and in the denomination of the Bank of England notes required for the uses of the public as currency of late years. Notwithstanding the great increase of population, and the acceleration of trading transactions which have taken place since 1844, the whole amount of Bank of England notes has actually diminished, and still continues to decline. But the 5*l.* and 10*l.* notes in circulation, which in 1851 were 9,362,000*l.*, had risen in 1856 to 10,680,000*l.*; the notes for 200*l.* to 1000*l.* had decreased from 5,856,000*l.* in 1852, to 3,241,000*l.* in 1857. (Report of same Committee, pp. iv., v.)

There is no means of learning what is the amount of gold, silver, and copper coin in circulation at any given period; because the amount is always liable to fluctuations, sometimes by reason of the exportation of sovereigns when the price of gold on the Continent makes it profitable to export; at other times, by the fresh quantities of sovereigns put into circulation owing to fresh importations of gold dust or bullion and other causes.

We will conclude this article by stating that the object of the existing law, with reference to the currency of this country, is to render the present mixed currency of metallic money and paper variable according to the rules by which a purely metallic currency would vary; and for further details and illustrations of this very difficult subject, the reader is referred to the Report and Evidence above cited, as containing the latest and fullest body of authorities.

CURRENTS. [Tidal Waters.]

CURRY POWDERS AND CURRY PASTES. [Curcuma Longa.]

CURRYING. [Leather.]

CURSITOR BARON, an officer of the Court of Exchequer, formerly appointed by patent to be one of the barons of the Exchequer. His duty, before the abolition of the office, was to attend at Westminster to open the court prior to, and after each term, to close it. Prior to 1833 he had various other duties to perform; but since the act 3 & 4

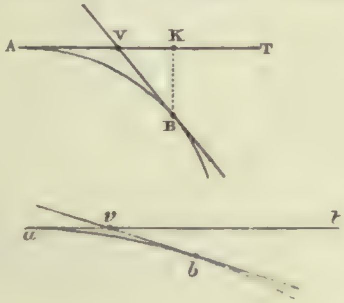
Will. IV. c. 99, much of the business of his office has entirely ceased; and the commissioners appointed under the 1 Will. IV. c. 58, having recommended the abolition of the office, this was recently effected on the death of the last Cursitor baron, 19 & 20 Vict. c. 86.

CURTATE (shortened), a term sometimes applied in geometry or astronomy to a line projected orthographically upon a plane. [PROJECTION.]

CURTEIN, or **CURTANA**, the name given to the first or pointless sword, carried before the kings of England at their coronation; also called the sword of King Edward the Confessor. It is mentioned by both these names in Matthew Paris, under the year 1236, when detailing the marriage ceremonial of Henry III. In ancient times it was the privilege of the earls of Chester to bear this sword before the king, which, in an emblematical form, is considered as the sword of mercy.

CURVATURE, a mathematical term expressive of the comparative degree of bending which takes place near the different points of a curve. If we imagine a point to describe a curve, that is, to be continually changing the direction of its motion, it may change this direction either more or less rapidly, that is, describe a line which is more or less curved. As in the article CONTACT, we shall first take a rough method of illustration grounded on the notions we derive from experience, and show how the accuracy of mathematics is introduced into the definition. We must suppose the reader to have gained the ideas which are introduced in the articles DIRECTION and VELOCITY.

Two points, A and *a*, are describing two curves, the directions of motion at A and *a* being A T and *a t*. That the first curve is more curved than the second, we may easily see; and if we wished to give some notion of the comparative degree of curvature, we might proceed as follows: Measure off equal arcs A B and *a b* (remember this equality throughout), say of one inch each; ascertain the directions B V and *b v*, in which A and *a* are proceeding when they arrive at B and *b*, and measure the angles B V T and *b v t*. If we find the first to be twice as great as the second, then the phenomenon by which we recognise curvature (change of direction) is twice as rapid in the first as in the second. Hence we say that the curvature of the first is twice as great as that of the second.



But here arises a difficulty of the same kind as that explained in VELOCITY. The preceding ratio of two to one is that of the whole effects of curvature from A to B, and from *a* to *b*. If the change of direction were uniform, that is, if every tenth (or other) part of A B gave a tenth (or similar other) part of the change of direction, it would then be indifferent whether we chose an inch for A B and *a b*, or any other length. But if the curvature do not continue uniform, the comparison of the united effects of all the curvatures from A to B, and from *a* to *b*, does not give a proper ratio of the comparative curvatures at A and *a*. The only curve in which this is the case is the circle, which is the curve of uniform curvature, just as the straight line is the line of uniform direction. But we immediately perceive that if A B and *a b* had each been the hundredth part of an inch instead of an inch, this objection would have held in a less degree; if the thousandth part of an inch, still less, and so on. Hence, as in VELOCITY, it is not by the proportion of the angles B V T and *b v t* that we get an exact and unalterable notion of what is taking place at A and *a*, but by the limit to which that proportion approaches, as B and *b* move back towards A and *a*, and the angles in question diminish without limit. This is the accurate terminal notion on which the mathematical theory of curvature is founded.

If the two curves had been circles (or curves of uniform curvature) it is found that the limit of the proportion of these angles (or the proportion of the angles themselves, which for circles is the same as its limit) is inversely as the radii of the circles; that is, doubling the radius of a circle halves its curvature, and so on. This suggests an absolute measure of the curvature at A. Let the second curve be a circle, so taken that B V T and *b v t* shall have a limiting proportion of 1 to 1, or shall continually approximate to equality. The circle *a b* has then at *a* the same curvature as the curve at A, and its radius (called the radius of curvature) being determined, the degree of curvature at A is known, as compared with that of any point of any other curve whose radius of curvature is known. This radius of curvature is thus determined: Draw the perpendicular B K and the chord A B. Then if the chord A B be always represented by the fraction *c* of an inch, and B K by *k* of an inch, the limit towards which $c \times c \div k$ approaches, as B is made to approach towards A, is the diameter of the circle of the curvature, or double of its radius. Or if through A and B a circle be always conceived to pass, which touches A V at A, the limiting position of that circle is the circle of curvature.

If the curve be referred to rectangular co-ordinates, and if x and y be those of the point A, $y = \phi x$ the equation of the curve, and ϕ' and ϕ'' the first and second differential co-efficients of ϕx, then

$$\text{Radius of curvature at A is } \frac{(1+\phi'^2)^{\frac{3}{2}}}{\phi''}$$

If ϕ be the angle made by the tangent with the axis of x, and s the arc from any given point to A,

$$\text{Rad. of curv. at A is } \frac{ds}{d\phi}$$

When the curve is not a plane curve, imagine it orthographically projected upon a plane. Its change of direction is then partly parallel to the plane, partly perpendicular to it, and the curve is said to have *double* curvature. But as this subject, together with that of the curvature of surfaces, is not of an elementary character, we shall not proceed further here, but refer to works which treat largely of the Differential Calculus.

The circle of curvature is also the circle of contact, or the nearest circle which can be drawn to the curve, just as the straight line of direction is also the line of contact, or the tangent. An infinite number of circles can be made to present the appearance of touching the curve at A [CONTACT], of all of which the circle of curvature comes the closest. Moreover, it always cuts the curve which it also touches (in the mathematical sense), except only at particular points; that is to say, the circle of curvature has in general a contact of the second order with its curve, in which case the circle always passes through the curve. But if at any particular point the contact should be of a higher and odd order, the circle of curvature does not pass through the curve.

CURVE, and CURVES, THEORY OF. A curve is a line which has *curvature*. Though the second of these terms be derived from the first, yet it is the notion explained in the preceding article which is preliminary to the explanation of the general term *curve*. Let a point move with a perfectly gradual change of direction, and it describes a curve.

Curves are said to be of the same species, in which the motion of the describing point is regulated by the same mathematical law. Thus the general law of the circle is, that all its points are equidistant from a given point. This law is the characteristic of the species; one circle is distinguished from another by the length of the constant distance supposed in the law of formation.

And in like manner as 0, or nothing, is classed under the general name of number or quantity, so the straight line itself (or the line without curvature) is, in algebra, spoken of under the general term *curve*. Or, in the last-mentioned science, the word means any line which is described by a point moving under one and the same law through every part of space which is consistent with the law.

The connexion of algebra with the doctrine of curves depends upon the method of co-ordinates (ABSCISSA, ORDINATE, CO-ORDINATES), by means of which every algebraical function whatsoever is connected with the properties of a curve. This is the point of greatest utility in the theory, namely, the power which it gives of representing to the eye all the varieties of magnitude which an algebraical function undergoes, while one of its letters passes through every state of numerical magnitude.

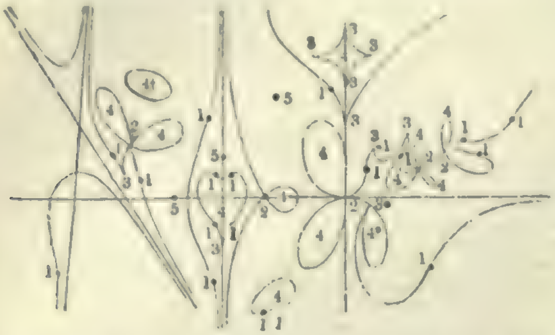
The number of curves which have received distinct names, out of the infinite number which may be drawn, is very small; we subjoin the names of those which are of most usual occurrence, referring to the several articles for further information, for the cases which are not presently mentioned.

1. Circle.
2. Ellipse.
3. Hyperbola.
4. Parabola.
5. Semi-Cubical Parabola.
6. Cissoid of Diocles.
7. Conchoid of Nicomedes.
8. Trisectrix.
9. Lemniscata.
10. Cycloid.
11. Companion of the Cycloid.
12. Harmonic Curve.
13. Trochoid.
14. Epicycloid and Cardioide.
15. Hypocycloid.
16. Epitrochoid.
17. Hypotrochoid.

Trochoidal Curves.

18. Curve of Sines, cosines, tangents, &c. [SINES, TANGENTS, &c., CURVES OF.]
19. Exponential or Logarithmic Curve.
20. Spiral of Archimedes.
21. Logarithmic Spiral or Equiangular Spiral.
22. Reciprocal Spiral.
23. Lituus.
24. Quadratrix of Dinostratus.
25. ——— of Tchirnhausen.
26. Catenary.
27. Tractory.
28. Syntractory.
29. Tractrix.
30. Ovals of Cassini.
31. Watt's Parallel motion curve.

The general characteristics of curves are extremely varied, and very few of them have received names. We subjoin a diagram, which will show all the varieties of figure most commonly considered in works on the Differential Calculus, premising, however, that we do not actually know any curve which contains them all. It would appear as if our figure contained several curves, but it must be remembered that in the algebraical sense many curves exist with branches completely unconnected, but all described under one law.



The several parts of the preceding are of continual occurrence; the following are the names and references:

(1). Points of inflexion or contrary flexure. [FLEXURE, CONTRARY.]

(2). MULTIPLE POINTS, double, triple, &c., according to the number of times the curve passes through them.

(3). CUSPS: the terms are hardly sufficiently well settled to enable us to say whether the 3* is to be considered a double point, a triple point, or not a multiple point at all.

(4). It is customary to call any part of the curve which encloses space an OVAL, though, according to the common meaning of the term, there is no oval in our diagram except 4†. Of 4* we hardly know whether it would be called an oval or not.

(5). Conjugate points [CONJUGATE]; when of a general law of description which gives ovals, a particular case is taken in which an oval disappears, it generally leaves behind it, so to speak, a single point which is included under the equation to the curve, but has no contiguous points. We should propose to call these points *evanescent ovals.* [INVOLUTE, EVOLUTE, CAUSTIC, CONTACT, TANGENT, ARC, AREA, ASYMPTOTE, MAXIMA and MINIMA, &c.]

Some remarks on a few of the curves in the preceding list of names are given here.

5. *Semicubical parabola.* The term *parabola* has been extended to mean any curve having an equation of the form $y=ax^m$, where m is positive. Thus $y=ax^3$ is the cubical parabola, and $y=ax^{\frac{3}{2}}$ is the semicubical parabola. The semicubical parabola is the evolute of the common parabola. The term *hyperbola* has been extended to any case in which m is negative.

8. *Trisectrix.* See this curve described in TRISECTION, and figured in TROCHOIDAL CURVES.

11 and 12. For the *Companion to the Cycloid*, see CYCLOID. The harmonic curve, so called because it, or a portion of it, is one of the simplest forms assumed by a vibrating string, has for its equation the relation between x and y implied in

$$x=a\theta \qquad y=b\,(1-\cos\theta).$$

12 to 17. These curves are all described in TROCHOIDAL CURVES.

20 to 24. See SPIRAL.

30. *Ovals of Cassini.* Dominic Cassini (see James Cassini's 'Astronomy,' vol. i. p. 149) proposed, as a better representation of the planetary motion than the ellipse, a curve in which the rectangle of the distances from any point in it to two fixed foci is constant. This curve is of the fourth order, and may be one oval, a lemniscate form, or two separate ovals, according to the ratio of the given rectangle to the square on the distance between the foci. It is hardly necessary to say that Cassini was wrong in his application of this curve: but the celebrity of his name has kept his oval or ovals among the curves which serve for exercise to beginners.

31. *Watt's Parallel Motion Curve.* The end of the beam of a steam-engine describes an arc of a circle; but it is required that the end of the piston-rod, which must be in some way attached to it, should describe a straight line, or a curve which is very nearly a straight line. Now at and near a point of contrary flexure the arc of a curve is very nearly straight. If two rods revolve round fixed pivots, their ends being connected by a third rod, the middle point of that third rod will describe a curve which has a point of contrary flexure; and if the lengths of the rods be properly taken, and if one of the rods be the beam of the steam-engine, the reciprocating rotatory motion of the beam may be made to communicate what is practically a reciprocating *rectilinear* (improperly called *parallel*) motion to the middle point of the third rod, on account of the arc described by that middle point containing the point of contrary flexure. A piston therefore may be attached to the middle point of the third rod, and the requisite condition is practically satisfied. The apparatus described in the article STEAM-ENGINE, and in Lardner's 'Steam-engine,' consists in the addition of a pair of rods which with the first and third compose a parallelogram moveable at all its joints. This is intended to furnish the same reciprocating rectilinear motion to a second piston placed at the new joint, which is nothing to our present purpose. Watt's parallel motion curve must be defined as the locus of the middle point of a straight line of given length, the ends of which describe arcs of circles.

The following considerations on the definition of the word *curve* will be useful to the young analyst:—

Geometrically speaking, a curve is described by a point which moves according to one uniform law, and does not describe a straight line. An oval, for instance, formed by arcs of circles in the manner described in books on mensuration, is not a curve, but a junction of several arcs of different curves: and even the two branches of an hyperbola cannot be said, in this primitive view of the subject, to be anything but two curves; accordingly they *were* called opposite hyperbolas.

But, algebraically speaking, the meaning of the word curve is much extended. Every curve, just defined, has one permanent equation connecting the abscissa and ordinate of every point in it. The converse is made true by extension of the definition of the word *curve*. All the points whose co-ordinates satisfy an equation constitute the curve to which the equation is said to belong. Let x and y be the abscissa and ordinate of a point; and $\phi(x, y)=0$, the equation which is to connect them. If this equation be satisfied when $x=a$ and $y=b$, the point whose co-ordinates are a and b is considered in every case as belonging to the *curve* whose equation is $\phi(x, y)=0$. The consequence is that a curve, or what is so called in algebra, may be either the simple curve of geometry—or a collection of such curves formed under algebraical modifications of one law—or a collection of such curves not even connected by one law—or an isolated point—or a collection of isolated points at finite distances from one another—or a collection of isolated points infinitely near to one another, but which nevertheless cannot be considered as forming one continuous branch of an ordinary curve. Or it may be any combination of two or more of these. We give some instances, as follows:—

1. The equation $y-m^2x^2=a^2$ belongs to both the branches of an hyperbola. If a change, m remaining constant, the hyperbola becomes a different hyperbola, with the same asymptotes as before. But if $a=0$, the equation belongs simply to those two asymptotes, that is, to two distinct and independent straight lines. In like manner the equation

$$(x^2+y^2)\,(x+y)=x^2+y^2+x+y-a$$

belongs to a complicated curve, with various branches. But if $a=1$, this curve resolves itself into two distinct curves, the straight line $x+y=1$, and the circle $x^2+y^2=1$. For the equation can then be reduced to

$$(x^2+y^2-1)\,(x+y-1)=0$$

which is satisfied whenever either $x^2+y^2-1=0$ or $x+y-1=0$ is satisfied. If a, instead of being $=1$, is only very near to 1, the curve approaches very near to the circle just mentioned throughout, and, except for great values of x, also to the straight line.

2. The equation

$$(x-a)^2+m(y-b)^2=0$$

belongs to a distinct pair of straight lines when m is negative. But when m is positive, it belongs to nothing but the point whose coordinates are a and b.

3. The equation

$$y = ax^2 + \sin x . x^{\frac{1}{2}}$$

belongs to a branch with an infinite number of intersecting convolutions, when x is positive: but when x is negative, it belongs to nothing but an infinite number of isolated points, situated at finite distances from each other on a parabola.

4. If $y=a^x$, a being positive, there is a continuous branch in which there is a positive ordinate for all values of x. There can be no negative ordinate except for values of x which have, when in their lowest terms, odd numerators and even denominators. But between any two values of x can be interposed an infinite number of such fractions. There is then a branch of the curve which, though it may be said to contain an infinite number of points, infinitely near together, cannot be called continuous. For there is no negative value of y when x is a fraction which has an even numerator and an odd denominator. These *pointed branches*, as they have been called, have only been recently considered. Their admission depends entirely upon definition. Those who would restrict the meaning of the word curve to something like its ancient signification, will reject them: but those who wish to look upon a curve as a tabulation in space of every possible value of x and y which will satisfy a given equation, must admit them. The few hints here given on the extension of the word curve are meant to excite the curiosity of those who have not been accustomed to look at geometrical interpretation as subordinate to algebra.

A distinction ought to be drawn between *algebraic geometry* and *geometrical algebra*. In algebraic geometry, in which algebra is brought to the assistance of geometry, the old notion of the meaning of *curve* might be retained. But in *geometrical algebra*, in which geometry is used in illustration of algebra, all the extensions which we have mentioned must be introduced. The use of this distinction would be, the elimination of disputes about words.

CUSCO-CHINA. There seems now no room to doubt that three different barks pass under this name: one, the produce of *Cinchona scrobiculata*, var. α *genuina*, called in Peru red Cusco bark. It approximates to the Calisaya bark: so much so that Guibourt has termed it *Calisaya léger;* but it differs from all the known cinchonas in the character of the alkaloid it contains. The second appears to be the produce of *Cinchona pubescens*, var. α *Pelletieriana*. This was the bark observed and described by Jobst (Buchner, 'Repert.,' xxxii. p. 464), and from which Pelletier procured the alkaloid which he called *Aricina*, by many used erroneously as a synonym for cusconia. A third kind passes by this name, which may probably be the white Jaen (Jen, corruptly), which Bergen assigns to the *C. pubescens*.

The alkaloid is procured by the same process as is used for cinchonia, which it resembles in its physical qualities, but differs in its chemical habitudes. The taste is more bitter, rather heating, and sub-astringent. It is equally insoluble in water, but easily soluble in alcohol and in sulphuric ether. It forms with acids salts which resemble those of cinchonia, but have a more bitter taste. The sulphate conducts itself singularly. A concentrated watery solution of this salt forms on cooling a tremulous jelly, which on drying becomes horny, but which, by the assistance of boiling water, resumes the jelly-like state. Cinchonia, quinia, and cusconia are supposed to be one base or radical with progressively increasing proportions of oxygen.

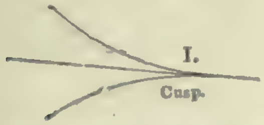
The formula of these is

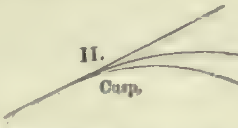
$$(C_4H_{24}Az_2) + O \text{ cinchonia.}$$
$$(C_4H_{24}Az_2) + O_2 \text{ quinia.}$$
$$(C_4H_{24}Az_2) + O_3 \text{ cusconia.}$$

This composition renders it worthy in the highest degree of the attention of medical men. The warmth which it excites points out the propriety of giving it in cold intermittents, and low typhoid states of the system.

CUSP (Cuspis, a pointed end), a mathematical term used where two branches of the same or different curves appear to end in a point. Thus, in an eclipse of the sun, the borders of the sun and moon make two cusps at their point of intersection.

In the theory of curves, the cusps which appear are always such that the two branches have a common tangent at the cusp, and they are distinguished into the cases in which the tangent lies between the branches or on one side of both.





In the actual determination of the position of cusps by means of ordinates to a given axis, there are two distinct ways of proceeding.

1. For cusps whose tangent is perpendicular to the given axis.
2. For cusps whose tangent is not perpendicular to the axis.

The first case ought in part to fall under the theory of maxima and minima; $\phi\, x$ being the ordinate, it is the case where $\phi' x$, the differential coefficient, becomes infinite and changes sign; or becomes infinite and afterwards impossible, having previously had two values of the same sign for each value of x. These cases give cusps of the first and second kinds, as shown in the two diagrams.

Many other cusps (namely, those whose tangents are oblique or parallel to the axis) are found by observing the points at which $\phi'' x$, the second differential coefficient, takes the form A, having previously had that of $A \pm B$; that is, in $\phi'' x$, the points must be found at which a term of double value vanishes and then becomes impossible. If for points immediately preceding, the $A + B$ and $A - B$ were of different signs, the cusp is of the first species; if of the same sign, of the second species. It would be useless to attempt separation of the theory of cusps from the general theory of curves, further than is contained by the preceding rules. There is no universal test by which they may be detected. The two species of cusps are said to be of the first and second kind, as marked. Few will remember which is the first and which is the second. It would be better to call them cusps of similar curvatures, and cusps of opposite curvatures.

CUSP, a term given by Sir James Hall, in his 'Essay on the Origin of Gothic Architecture,' and now commonly applied to the foliated points terminating the internal curves of the trefoiled, cinquefoiled, &c., heads of pointed arch windows. Cusps were originally introduced, both on the Continent and in England, in the later period of First Pointed architecture. In the earliest instances they were simple points or finished with a small leaf, and they sprung directly from the soffit or under side of the arch. In what is known in England as Decorated Gothic, the cusps spring from the inner moulding of the arch, and are terminated with leaves, flowers, curls, &c. In the latest or Perpendicular style, cusps are sometimes very florid in style. The beauty of the tracery in a pointed window is largely due to its cusps.

CUSPARINE, an alkaloid found in the *Cuspara febrifuga*, and of which little is known.

CUSTOMARY FREEHOLDS. [COPYHOLD.]

CUSTOM-HOUSE. An office established in seaports, at which the customs-duties are collected from importers and exporters of customable commodities.

CUSTOMS, or USAGES, in law (consuetudines), are either general or local. The first kind consists of those usages which have prevailed throughout England from time immemorial, but, without their original institution having been handed down to us in records or writing, have been recognised by judicial decision,* and form that common law, or lex non scripta, which is the chief foundation of English jurisprudence. To like immemorial usage is to be ascribed the existence of such parts of the civil and canon laws, as from the earliest times have formed the rule in the king's ecclesiastical, military, and admiralty tribunals, and also in the courts of the two English universities. These laws of foreign origin subsist however only as inferior branches of the customary law, subject to the superintendence and control of their proceedings by the superior temporal courts, and to a strict observance of the rules of construction assigned by these last to the statute law.

These general customs of the realm, which form the common law, properly so called, alone warrant the existence and jurisdiction of the king's superior courts; and can only be drawn into question there. These general customs, as originally methodised by the Saxon kings, and in some cases modified in the early Norman reigns, supplied those fundamental rules by which, in cases not provided for by express enactment, the course of inheritances, the interpretation of acts of parliament, and most of the remedies for civil and criminal injuries are regulated. Numerous axioms essential to the administration of common justice have no other binding force than ancient and uninterrupted usage, which has obtained the force of law by the recognition of the courts. [COMMON LAW.]

Among these general customs must be enumerated those laws which govern the particular bodies of men to which they relate; merchants, innkeepers, carriers, owners of land adjoining the sea coast, &c., &c., as well as the inhabitants of particular counties or boroughs, in the particular instances of gavelkind and borough English. That custom called the law of the road, by which riders and drivers are expected to keep the left hand, as well as that respecting servants hired at yearly wages, by which either master or servant may determine the contract at a month's warning, or on paying a month's wages, have been recognised by the courts from time to time as parts of the common law. These, like the rest, originated in general convenience, and being gradually drawn more into notice by frequent recurrence, have been finally sanctioned by judicial authority. For immemorial customs may be extended to things and circumstances which arise at the present time. Thus a custom from time immemorial that all officers of a court of justice shall be exempt from serving other offices includes offices created within the time of legal memory, but cannot be enlarged beyond the extent to which the use has been carried; for that, and not the reason of the thing, determines the courts in declaring what the law is in such cases.

The customs by which the superior courts of Westminster Hall regulate their administration of justice, are popularly termed their practice. These rules are founded on ancient usage, and, in respect of their universality, form a part of the common law without its being necessary to allege custom or prescription to warrant them.

Where a custom is already part of the common law, the superior courts will take judicial notice of its existence as such, without requiring it to be stated in the written pleadings. Thus each of these tribunals will take judicial notice of its own customs or practice as well as of that of the rest; whereas the practice of inferior courts, as well as particular or local customs, extending to certain persons or districts only, being therefore different from and contrary to the common law, must, with the exception of gavelkind and borough English, be set forth with due precision.

This, though an observation apparently technical only, forms in its application the test by which we distinguish general from the local or particular customs just described. These latter customs must necessarily have had their origin in the peculiar wants of their respective districts, and are the remains of that multitude of similar usages from which Alfred and his Saxon successors collected those laws which may be considered as forming the common law of the nation at the time.

Many of these customs, for reasons now forgotten, were permitted to remain in some counties, cities, and manors, &c., in their former vigour, though at variance with the laws of the rest of the nation, and are confirmed by Magna Charta and other acts of parliament. Such are the customs of gavelkind (abolished in Wales by stat. Henry VIII.), by which all the sons inherit alike; of borough English, by which lands held in burgage tenure descend to the youngest, instead of the eldest son; and of some boroughs, that widows shall have dower of all, instead of a third of their husband's lands. A more striking instance is that of the custom in many cities and towns to hold courts for trial of causes without royal grant. The particular customs of manors as to descent, &c., are also of this kind, and bind the copyhold and customary tenants. The existence of every such local custom, with the exceptions above noticed, as well as its application in each particular case, must be alleged in the pleadings, and proved, like any other fact, before a jury: sometimes they are open to evidence without being pleaded. Under no circumstances could these questions be entertained by an ecclesiastical court, nor now by the Court of Probate, without the consent of the party impugning the custom.

---

* Bracton's definition of a custom is this—"Consuetudo vero quandoque pro lege observatur, in partibus ubi fuerit more utentium approbata, et vicem legis obtinet; longævi enim temporis usus et consuetudinis non est vilis authoritas." (Bracton, fol. ii., ed. Lond. 1569.) This is no inapt definition of a custom observed as if it were law, by those who find it convenient and reasonable; but we can hardly conclude from this passage that this excellent old writer clearly saw that custom could not be law till made so by the sovereign power, or those to whom the sovereign power has delegated parts of its authority.

Such customs of London as do not concern the property of the corporate body itself are proved by a peculiar mode, that of a certificate to the superior courts of law from the lord mayor and aldermen, conveyed by the mouth of their recorder in a solemn ceremonial; without this certificate these courts will not take judicial notice of them.

A particular custom to be valid must have been used "from time whereof the memory of man runneth not to the contrary." This is "prescription," or "title by prescription;" and more accurately describes what is commonly called "time immemorial," which means, says Littleton, "that no living witness hath heard any proof or had any knowledge to the contrary," and as Lord Coke adds, "that there is no proof by record or writing or otherwise to the contrary." It has been doubted whether a prescription (in its proper sense) and a custom can coexist. There is some curious learning on this point collected in the arguments and judgment in Blewitt *v.* Tregoning, 3 Ad. and Ellis. It was held that a custom in a particular market that every pound of butter sold in it should weigh 18 oz. was bad, being directly contrary to a statute of Charles II., which enacted that every pound avoirdupois throughout the kingdom should weigh 16 oz. only. The right to a particular custom must have been continued within time of memory peaceably and without lawful interruption, and will not be lost by mere disuse for ten or twenty years; though in such case to establish it by proof becomes more difficult. But it cannot stand against an express act of parliament to the contrary, for that itself proves a time when the right to such a custom could not exist. It must also be so far reasonable, according to the standard warranted by authority of law that, though no particular origin can now be assigned for it, or though the state of things in which it is known to have arisen has been altered, no good legal reason can be given against its continuance. If it may have had a legal and reasonable origin, it shall be presumed that it actually had it; and its varying from the general law forms no objection, for that is the very essence of a particular custom: but if it be so contrary to any known rule or principle of law, or to the good of the public, or of a multitude of persons, that it cannot be presumed to have had a reasonable commencement in voluntary agreement for some beneficial object, as for securing possessions, promoting trade, or suppressing fraud, it will be void. Thus no length of usage would render good a custom of the secretary of state's office to issue warrants in general terms against the authors, printers, and publishers of a libel, without naming them; that course being contrary to clear and well-settled principles of law, which will not suffer a mere officer to decide on the individuals to be imprisoned. Again, a custom in an inferior court to try causes by six jurors was held bad, as contrary to the common law, though saved in Wales in some instances by a statute of Henry VIII., confirming such custom where it then existed. But long usage and acquiescence in one uniform payment, or in exempting persons particularly situated from contributing to it, are cogent evidence that it is reasonable; for as Lord Mansfield once said, it cannot be presumed that during a long period of years one half the parties were knaves in wrongfully receiving that to which they were not entitled, and the other fools for submitting to an unjust demand. It belongs to the judges of the courts to decide on what is reasonable when brought judicially before them.

Where a custom is harmless in itself, and affords recreation to a number of persons, though to the temporary inconvenience of an individual, it will be upheld and referred to a legal origin. Thus a custom for the inhabitants of a parish to play at cricket, or dance on private property in the parish, was held good, as the lord might have annexed this condition to his original grant of the land. A custom must also be certain as to the description of parties benefited, and compulsory, without its depending on the caprice of any third person whether it can be acted on or not. It must also be consistent; for repugnancy to any other local custom would be plainly contrary to that origin in common consent on which alone it stands; and lastly, it must be strictly pursued, being derogatory of the common law.

Local custom varies from prescription in this: the former is alleged in legal forms as existing not in any person certain, but within a certain named district, without showing any legal cause or consideration for it; whereas prescription must have a presumed legal origin, and is either a personal right, always claimed in the name of a person certain and his ancestors, or those whose estate he has, or by a body politic and their predecessors, or else is in a *que* estate; namely, a right attached to the ownership of a particular estate, and only exercisable by those who are seised of it. All customs of cities, towns, and boroughs, by which persons not freemen were prevented from keeping shops or using trades or handicrafts within them, were abolished by 5 & 6 Will. IV., c. 76, s. 14. [PRESCRIPTION.]

Customs of traders, or seamen, as also of agriculture, mining, &c., will be followed in the construction of contracts, unless they are inconsistent with their express terms, and, subject to that condition, they are admissible even to annex incidents to them as to which they are silent. The "custom of the country" means the custom of all parts of the country to which it can in its nature be applied. Thus a custom that land accruing imperceptibly to the sea-shore belongs to the owners of the shore, applies to all such parts of the realm as adjoin the sea, unless limited in terms to a particular district.

The immemoriality of a particular local custom may be sufficiently proved by living witnesses attesting regular existence for twenty years, unless contradicted by contrary proof. Upon this doctrine will be found to depend a great variety of public as well as private rights to ancient offices, estrays, treasure trove, wreck, nomination of juries, &c.; as well as to tolls of markets, port duties, tithes, ancient rents, &c., and to exemptions from those burdens. The numerical amount of instances in which the privilege claimed can be proved to have existed must be considerable or not, according to the frequency or the rarity with which they may be naturally expected to recur. Thus in a copyhold custom of surrendering in fee so as to bar an entail, a single instance of user, though incapable of making a custom, is evidence sufficient to support it, if not unreasonable in itself.

Reiterated facts of user make a custom of trade; but the mere opinion of merchants is not sufficient for that purpose; nor can any course of action pursued under colour of a custom of merchants alter a general rule of common law when established by judicial decisions.

A long continued usage for exempting particular persons from a local burden, will, if necessary, be supported by presuming that it originated in an act of parliament now lost, though no length of usage will countervail the terms of a statute to the contrary.

CUSTOMS-DUTIES consist for the most part of taxes levied upon goods and produce brought for consumption from foreign countries; such duties are sometimes collected upon exports made to foreign countries, and upon goods and produce passing from one port to another of the same country. Of this nature were the duties on coals, slate, and stone, carried coastwise from one port in the United Kingdom to another, which duties were repealed in 1831. With the exception of a small-rated export duty upon coals, hare-skins, rabbit-skins, and sheep's wool, and an *ad valorem* duty of one-half per cent. on the shipment to foreign countries of some articles of British production, the whole customs-revenue of this kingdom is now derived from duties charged upon the importation for consumption of foreign and colonial merchandise.

The earliest statute passed in this country, whereby the crown was authorised to levy customs-duties, was the 3rd of Edward I. The mode long employed in the collection of these duties was to affix a certain rate or value upon each kind or article of merchandise, and to grant what was called a *subsidy* upon these rates. This subsidy was generally one shilling of duty for every twenty shillings of value assigned in the book of rates. The early Acts granting these duties speak of them as subsidies of tonnage and poundage. The word tonnage was applied to a specific duty charged on the importation of each tun of wine, and the exportation of each tun of beer; and the word poundage was applied to other articles valued as already explained.

The first "book of rates agreed upon by the House of Commons," is believed to be that compiled by a committee in 1642, during the reign of Charles I., and published under the authority of the House by Lawrence Blaiklock. The next book of rates of which we have any record, was also published by order of the House of Commons, in 1660, the year of the restoration of Charles II. In the fifteenth and twenty-second years of the reign of that king, the principle of poundage was altered as respected some articles, and upon those articles specific duties were charged instead, though the system was still followed with regard to the great bulk of articles. But in the reigns of William III. and Anne many additional specific rates were imposed, in place of the valuation for the subsidy. This course of substitution was continued from time to time, and some other innovations were adopted by which the simplicity of the ancient plan was destroyed; so that in a work of authority, published by Mr. Henry Saxby, of the Custom-House, London, in 1757, we find as many as thirty-nine principal branches of customs-duties, with subdivisions applying to different kinds of goods, thereby introducing a degree of complication into the subject which must have caused great embarrassment to traders.

The difficulties here mentioned were increased by the great number of acts of parliament passed from year to year for altering the duties or regulations of this branch of the revenue; and the great bulk and intricacy of the customs-laws had caused such inconvenience, that about the year 1810 the lords of the Treasury employed Mr. Jickling to prepare a digest of those laws. Five years were employed in completing this task, and some idea may be formed of the laborious nature of the work, and of the necessity for its performance, from the fact that the digest forms a large octavo volume of 1375 pages. The work is intituled 'A Digest of the Laws of the Customs, comprising a Summary of the Statutes in force from the earliest period to the 53rd

George III., inclusive.' The effect of the numerous fresh enactments to impair the usefulness of this exposition of the revenue laws was very soon apparent, and in 1823 the late Mr. Deacon Hume, then Comptroller of the Customs in the port of London, was appointed by the Treasury "to undertake the preparation of a general law or set of laws for the consolidation of the Customs of the United Kingdom." In the performance of this duty, Mr. Hume prepared eleven bills, which received the royal assent in July, 1825, and came into operation 1st of January, 1826. These Acts were 6 Geo. IV., caps 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116. The first of these Acts repealed 443 statutes, many of which were obsolete. In 1833, eight of Mr. Hume's Acts were repealed or altered by 3 & 4 Wm. IV., caps. 50, 51, 52, 53, 54, 55, 56, 57. These Acts no doubt effected great improvements in the management of the customs, but cap. 56 enumerated no fewer than 1150 different rates of duty chargeable on imported articles, all other articles paying duty as "unenumerated." In 1840, Mr. Porter, of the Board of Trade, in his evidence before the Parliamentary committee on import duties, showed that out of a total amount of 22,962,610*l.* of customs-duties received in 1839,

	£
17 articles produced $94\frac{1}{2}$ per cent. or . .	21,700,630
29 articles produced $3\frac{9}{10}$ per cent or . . .	898,661
46 articles produced $98\frac{2}{5}$ per cent. or . .	£22,599,291

In 1842, Sir Robert Peel effected some improvements in this system, which were carried into effect by 5 & 6 Vict. c. 47. This Act reduced the duty on about 750 different articles on which the receipts had amounted to about 270,000*l.* The general principle of the measure was to reduce the duty on raw materials to about 5 per cent., to limit the highest duty on partially manufactured materials to 12 per cent., and on complete manufactures to about 20 per cent. The number of articles in the tariff was now reduced to 813. Foreign horned cattle, sheep, goats, swine, salmon, soles, and other fish, and fresh beef and pork, which had been prohibited formerly, were admitted on paying a duty under the tariff of 1842. In 1844 the duty on foreign wool was abolished. In 1845, Sir Robert Peel effected further improvements in the tariff by abolishing the duty on cotton wool (about 680,000*l.*) and on 430 other articles, on which the duty amounted to 320,000*l.* By this plan expenses of warehousing were saved, and a number of troublesome accounts and impediments to business were got rid of; but for statistical purposes the Customs department retained the power of examining articles which do not pay duty. The paramount object of the tariff reform of 1845 was to encourage the abundance and cheapness of raw materials of manufacture, and the estimated amount of the taxes repealed was 3,614,394*l.*

The following is an abstract from an official 'Expository Statement,' showing the net annual produce of the duties of Customs on all articles imported into the United Kingdom in two years preceding and in two years following the establishment of the new tariff (5 & 6 Vict. c. 47).

Articles producing under the New Tariff.	Old Tariff. £	New Tariff. £
Under £100 . . .	19,037	8,040
£100 to 500 . . .	71,972	34,461
500 to 1000 . . .	69,032	36,258
1000 to 10,000 . . .	570,718	317,492
10,000 to 50,000 . . .	706,991	511,570
50,000 to 100,000 . . .	389,006	395,603
100,000 and upwards . . .	20,810,542	21,417,462
Exempt from duty or prohibited .	196	,,
	22,637,494	22,720,886

On 598 articles, the duties on which were altered in 1842, 1843, and 1844, the receipts were 3,851,259*l.* in 1840 and 1841, and 2,478,306*l.* in 1843 and 1844.

On 214 articles, the duties on which were not altered in 1842, 1843, and 1844, the receipts were 18,114,525*l.* in 1840 and 1841, and 19,094,890*l.* in 1843 and 1844.

In 1844 the gross receipt on the following five articles was 15,728,857*l.*:—

Sugar	£4,758,415
Tea	3,884,726
Tobacco	3,093,217
Foreign spirits	2,193,067
Wine	1,799,430

The net amount of duties collected in the United Kingdom on imported articles, after the deduction of drawbacks, repayments, &c. in the last two years of the old tariff and the first two years of the new tariff, was as follows:—

	£		£
1841 . .	23,302,152	On corn, included in preceding column.	568,341
1842 . .	22,356,324		1,363,978
1843 . .	22,450,074		758,295
1844 . .	23,864,494		1,098,383

The following table shows the nature of the tariff previous to the alterations in 1845:—

Articles each producing in 1843–44.	Articles in a raw state for Manufactures.	Articles partially manufactured.	Articles wholly manufactured.	Articles of Food.	Not comprehended under the preceding heads.	Total.
	No.	No.	No.	No.	No.	No.
Under £100	144	54	113	46	91	448
£100 to 500	45	19	31	15	27	137
500 to 1000	16	5	17	6	6	50
1000 to 10,000	28	11	27	28	15	109
10,000 to 50,000	6	5	5	7	2	25
50,000 to 100,000	2	..	..	3	..	5
100,000 and upwards	3	1	1	12	..	17
Exempted from duty or prohibited . .	8	..	2	4	8	22
Total . .	252	95	196	121	149	813

In 1846 the Customs duty on corn was in fact repealed, only a fiscal duty of 1*s.* per quarter being retained. In 1850, (13 & 14 Vict. c. 95) further restrictions were removed; manufactured goods of the Isle of Man and the Channel Islands were admitted free into the United Kingdom; tea and tobacco were allowed to be received by them either from the United Kingdom or elsewhere; and the duty was taken off stringy bark-wood, blue gum-wood, locust-wood, trenails, and some other woods used for ship-building and for shovel-hilts, and also the export duty on coals and culm. The duties on wood received some further alterations in 1852 by the 14 & 15 Vict. c. 62. In 1853, by 16 & 17 Vict. c. 54, the duties on 134 articles, including butter and cheese, were entirely removed, and a reduced tariff imposed on 260 articles, including tea, the estimated amount of the reduction being 1,499,474*l.* In 1856 old metal of any sort, fit only for re-manufacture, was admitted duty free, and in 1857 plums and a few other articles. In 1857 the duty on platina and chloride of lime was repealed, and a few other articles reduced. Notwithstanding these continued reductions, both in the number of articles and the rate of duty imposed, the amount of the customs' duties for the year ending Dec. 31, 1858, was 24,149,215*l.*

The management of the revenue of Customs is committed to a board of nine commissioners, acting as a subordinate department of the Treasury. The commissioners receive a salary of 1200*l.*: the chairman receives 800*l.* in addition, and the deputy-chairman 500*l.*

Nearly one-half of the Customs revenue of the United Kingdom is collected in the port of London, and about one-fifth of the whole in the port of Liverpool. In 1843 the amounts collected at five principal ports was as under:—

London	£11,354,702
Liverpool	4,121,522
Bristol	996,750
Dublin	977,890
Hull	525,418

In 1858 the total amount of the duty was 24,149,215*l.*; to which England contributed 19,619,346*l.*, Scotland 2,264,816*l.*, and Ireland 2,265,053. The chief ports in the United Kingdom stood as follows:

London	£12,332,061
Liverpool	3,622,503
Bristol	1,296,550
Hull	282,387
Newcastle	262,867
Plymouth	228,372
Glasgow	801,895
Greenock	654,694
Leith	479,622
Dublin	1,018,226
Belfast	383,089
Cork	275,724

Those articles of which the importation is prohibited are termed *contraband*, from the Italian *contrabando*, against the proclamation. Since the adoption of the warehousing system in this kingdom, the list of goods the importation of which is prohibited has been made exceedingly short; it comprises at this time (1859) only the following articles:—

Arms, ammunition, and utensils of war, by way of merchandise, except by license from her Majesty for the public stores only.

Books first printed in the United Kingdom, and reprinted in any other country and imported for sale. Notice must be given to the commissioners of Customs by authors or owners that copyright is subsisting.

Clocks or watches, with any mark or stamp representing any legal British assay mark or stamp, or purporting to be of British make, or not having the name and abode of some foreign maker visible on the frame and the face, or not being complete.

Coin, counterfeit, or not of the established standard in weight and fineness.

The list of articles contraband as regards exportation from the United Kingdom is still more limited.

The schedule of prohibitions to importations was formerly much more extensive. Under the Customs Act, 3 & 4 Will. IV. c. 56, cattle, sheep, fresh meat or slightly salted, and fish, were contraband, but under the tariff established by 5 & 6 Vict. c. 47, they have ceased to be so. Tools, utensils, and machinery, for exportation, were also contraband without a license was obtained from the Board of Trade. The Act 6 & 7 Vict. c. 84, however, repeals, with some exceptions, the prohibition against machinery.

There are some other prohibitions by which trade in certain articles is restricted; but these refer to the manner in which the trade may be conducted, as the size of the ship, or the package, or the country from or to which the trading may take place, and these being only of the nature of regulations, the articles in question cannot be considered contraband. The list of articles prohibited by many foreign countries is much larger than that enforced in this country; though the system in the case of some of those countries has of late been somewhat relaxed. The tariff of Russia is however still principally filled by designating articles which are contraband.

Another sense in which the term contraband is applied refers to certain branches of trade carried on by neutrals during the continuance of war between other countries. It has always been held under these circumstances, that belligerents have a right to treat as contraband, and to capture and confiscate, all goods which can be considered munitions of war, under which description are comprehended everything that can be made directly and obviously available to a hostile purpose, such as arms, ammunition, and all kinds of naval stores, and all such other articles as are capable of being used with a like purpose, such as horses, and timber for building ships. Under some circumstances, provisions which it is attempted to convey to an enemy's port are contraband, as when a hostile armament is in preparation in that port. These restrictions rest upon principles which are reasonable in themselves, and have been generally recognised by neutrals; others which have at various times been enforced or attempted to be enforced have been contested, but a description of this branch of the subject belongs rather to the matter of International Law, than to a description of contraband trading.

It may be mentioned that all legal disputes respecting the payment of the Customs duties, between the merchant and the crown, are placed for the most part under a summary jurisdiction unknown to the common law, as are most matters of taxation. The popularly constituted tribunal of a jury was early found not to be adapted for the enforcement of laws which, as they interfere with the pocket, must necessarily always be unpopular. The Court of Exchequer, in the last resort, has the control over proceedings for the recovery of this and other branches of the revenue; and in such proceedings the party proceeded against is obliged to prove that he has paid the duties or done the act required, which is contrary to the rule usually observed in the courts.

CUSTOS BRE'VIUM. Officers so called existed until lately in the Courts of Queen's Bench and Common Pleas. They received and had the custody of all the writs returnable in their respective courts, filed warrants of attorney, and various other documents connected with the business of the courts. By the Act 1 Will. IV. c. 58, these offices (of which the duties were performed by deputy) were abolished in both courts, and compensation granted to their possessors. The office in the Court of Queen's Bench was held by Lords Kenyon and Ellenborough jointly, and the compensation granted them was 2089*l.* 17*s.* 4*d.* per annum.

CUSTOS ROTULO'RUM is the chief civil officer of the county, to whose custody are committed the records or rolls of the sessions. He is always a justice of the peace and of the quorum in the county for which he is appointed. The lord-lieutenant has the chief military command of the county, and his office is quite distinct from that of custos rutolorum; but it is the invariable practice to appoint the same person to both offices, in whom is united the highest military and civil authority within the county. By statute 37 Hen. VIII. c. 1, and 1 Will. III. c. 21, he is to be appointed under the sign manual. As he has the custody of the rolls of the sessions, he should attend there in person or by deputy; and this duty is usually performed by the clerk of the peace as his deputy.

CUTLERY. This is a general name for cutting instruments made of steel. Its application, however, is not very definite; for it may or it may not include workmen's tools, and is seldom considered to apply to swords. These last-named implements are, so far as the United Kingdom is concerned, made almost wholly at Birmingham; whereas, table knives and forks, pen and pocket knives, razors, lancets, scythes, saws, scissors, snuffers, shears, spades, chisels, awls, plane-irons, &c., are made more largely at Sheffield than in all other parts of the kingdom combined. This is one of those examples of localisation in manufactures, so difficult to trace to its origin.

Table-knives are made of various qualities of metal, from the merest iron up to the finest cast-steel. We will take a medium quality as an example of knife-making. A piece is cut off from a bar sufficient for one knife. The tang, or part which goes into the handle, and the shoulder, between the tang and the blade, are usually made of iron, fashioned by heating, welding, hammering, and swageing. When thus rightly put together, the whole is again heated, and brought into the proper form by further hammering and swageing. The blade is then made red-hot; plunged into cold water to harden; gradually heated again to give the proper temper or elasticity; ground flat and smooth on a large revolving stone; ground sharp at the edge on a smaller stone; and finally polished on a leather-edged wheel faced with a mixture of glue and emery.

Razors are made nearly in the same manner as table-knives, but with more care in the several processes. After the first rough forging, the concavity of the surfaces is produced by hammering the blade on the rounded edge of an anvil. This concavity or hollowing is necessary, to bring the edge to such a degree of thinness as to render keenness attainable; and according as the edge is to be keen or strong, so is this concavity made more or less in degree. The tempering is a much more important process in a razor than in a table-knife, and is dependent on principles which the cutlers themselves do not well understand; the colour of the steel, rather the temperature in degrees of a thermometer, is regarded as the chief test of the heat employed. The grinding and polishing finish the processes.

Table-forks are usually made of commoner steel than knives. A square rod is hammered while in a red hot state, to give roughly the form of the tang and shank; and when again heated, the form is finished by means of a die and swage or stamp. The prongs are fashioned by stamping, by means of a die brought down very heavily upon the steel; the prongs and the middle part of the fork are thus formed, leaving a very thin substance of steel between the prongs, which is afterwards cut out and expelled by means of a fly-press. The forks, thus far made, are heated, then gradually cooled to soften the steel, then filed, then heated again, then suddenly cooled to harden, then ground all over the surface to a smooth and even condition, and finally polished. Of some peculiarities connected with the grinding of forks, we shall speak presently.

Pen- and pocket-knives afford many illustrations of a remarkable diversity of processes in the production of an article which is to be sold at a small price. The blades are made nearly in the same way as those of table-knives; but separate attention is necessary for the bits of steel for the springs, the inner scales of metal which form the framework of the knife, the outer scales of ivory or some other substance which forms the visible handle, and various small pins or rivets. All these fragmentary portions of a knife are put together by a skilled workman; and so numerous are the adjustments, that a common two-bladed knife will pass through his hands seventy or eighty times.

Scissors are made nearly in the same way as knives and razors. Each half is forged, swaged, tempered, ground, and polished separately; but there is a particular series of processes, aided by appropriate tools, for producing the bow or handle. The rivetting, grinding, and polishing, require considerable care.

Grinding.—The work performed by the Sheffield grinders deserves a little separate notice, on account of the peculiar relation which it bears on the one hand to the different kinds of cutlery, and on the other to the health of the workmen. The grinding of table-knives was formerly done upon dry stones, and was considered very injurious to the health of the men. Numerous attempts have been made at various times to remedy the evil, or to lessen its intensity. The most successful plan hitherto devised consists in the employment of a revolving fan, which is connected with a pipe extending from the front of the stone to the exterior of the building; the action of the fan produces a powerful draught in the pipe, which carries off the particles of grit and steel set free during the process of grinding. Were it not for the strength of this current, these particles would be inhaled by the workman, and produce the distressing complaint known as the grinder's asthma. The best preventive of all is to use a wet grindstone; but some kinds of cutlery will not bear this. The better kinds of razors are shaped before they are hardened; and this shaping is effected on a dry stone. The reason for this is, that a stone revolving in water is much softer than when dry; and the action of shaping producing a sort of scraping effect, the wet stone wears away very quickly. As razors, moreover, are shaped on very small stones, there would be considerable loss of time in preparing new ones. The steel also being soft, the operation is more rapidly performed, and no injury is done to the blade by frictional heat. Forks are always ground on dry stones; and hence the most injurious effects are found amongst fork-grinders. During forty years past, the Society of Arts has been endeavouring to introduce some amelioration into the processes of fork-grinding at Sheffield, and needle-grinding at Redditch; but these efforts have not been seconded by the workmen. Mr. Abraham invented a mouth guard, consisting of a small wooden frame, the upper and lower pieces of which are made curved to fit the lips; in this are fixed two or three layers of crape or muslin—studded with several small magnets to arrest a considerable portion of the deleterious matter before it can reach the crape; to the upper part of the wooden frame is attached a bent wire, to which crape is affixed for protecting the nostrils; and the whole is fastened by two strings passing round the head and tying behind. The fork-grinders refuse to employ this mouth-guard or the revolving fan; they prefer to die of grinder's asthma at thirty or forty years of age. Three causes have been assigned for this recklessness—the troublesome confinement of the mouth-guard; the cost of the ventilating fan; and the fear lest wages should lessen if the grinder's employment became more healthy!

Handles, though not cutlery, form an important branch of Sheffield industry. Indeed not merely one, but many branches; for there are separate workers in ivory, bone, horn, mother of pearl, and other substances, so largely used for handles. Those handles which have a hole for receiving the tang of a knife or fork are known in Sheffield language as *hafts;* while those which consist of two pieces adjusted to their places by rivets, as in the case of clasp-knives, are called *scales*. The various kinds of hafts and scales are made by sawing, planing, filing, piercing, pressing, &c., according to the material employed.

Various other processes connected directly or indirectly with the cutlery trade will be found noticed under FILE; SAW; STEEL.

Certain peculiarities in the Sheffield cutlery operations deserve notice. Two special kinds of buildings in that town are technically known by the short names of *tilts* and *wheels*. A tilt is a building containing all the mechanism necessary for working enormous tilt-hammers. All the steel for the best cutlery is tilted before being used; it is heated to a certain temperature, and then beaten for a considerable time all over its surface, to close up the pores, and render the metal as dense and close as possible. At many of the tilts, or tilt-works, the operations are entirely confined to this tilting or hammering of steel, such tilters working for a large number of cutlers and steel manufacturers. The *wheels* are places in which nothing is done but grinding cutlery and edge-tools upon grindstones or wheels. Formerly these grindstones were worked by water-wheels, turned by some of the rivers which flow through the valleys around Sheffield; and hence the origin of the name wheel, as given to these places; but now large buildings have been constructed, supplied with steam-power; and here the owner either grinds cutlery and edge tools for other persons, or lets out workshops and steam-power to workmen at a definite rental. Such a system could not be profitably conducted, except in a town where the manufacture is carried on very extensively. The fork-grinders, already adverted to as victims of an obstinate adherence to unhealthy processes, form a sort of community by themselves; they work mostly in villages a short distance from Sheffield, rather than in the town itself. The division of labour is remarkable at Sheffield. There is nothing analogous to the factory system of the cotton manufacture; no establishment where a rough piece of iron enters at one door, and comes out finished cutlery at another. A Sheffield manufacturer, generally speaking, has no large manufacturing establishments; he buys his steel of one firm, has it forged by another, ground by another, and finished by another; or he will purchase ready-made goods from manufacturers of less capital; or he will advance money to workmen to purchase material, and agree to give a certain price for the finished articles. It is a mode of conducting business in some degree intermediate between those of the manufacturer and the merchant, as those designations are usually understood. There are a few large firms, however, which have establishments which might be called cutlery factories.

During the last few years, the cutlers of Sheffield have been warmly interested in the question, whether or not the excellence of their manufactures is maintaining its rank, relatively to those of the continent. It is known that the French cutlers were greatly struck by the Sheffield goods displayed at the Great Exhibition of 1851. The quality of the best kinds was better than they could produce. They did not very readily acknowledge the fact at the time; but they determined to profit from the lesson they received, by introducing sundry improvements. When the Paris Exposition was held in 1855, Mr. Moulton, of Sheffield, acted as a member of the jury on that class of exhibited goods which included cutlery. Not as a juror, but in his private capacity, he wrote to Mr. Wilson Overend, chairman of the committee of Sheffield exhibitors, a letter which excited vexation if not surprise among his townsmen, especially when that letter got into the French as well as the English newspapers. He said: "It has been my opinion for some time, that the French were superior to us in point of design for their ornamental work. This I find to be the case in the better kinds of cutlery. In this respect they are superior even to what I expected. And not only so; but the workmanship, or what may be called putting-together, is I consider superior to our best class of manufactured goods. If they are deficient at all, I think it is in their grinding, and I think their table-knives too thick. The Prussians are improving very fast, both in tools and cutlery, and I am informed export to a considerable extent. Many of their goods exhibited were near approaches to Sheffield. I came to the conclusion, then (which is not a new one with me), that Sheffield cutlery, instead of improving as the trade advances in other ways, has been on the decline. While foreigners have been progressing, we have been either stationary or going backwards. There are exceptions of course." The Sheffield cutlers, smarting under this judgment passed by their townsman, met, and passed a formal resolution as a trade-guild, that the opinion of Mr. Moulton was incorrect: in other words, that Sheffield had *not* fallen behind France in the excellence of its cutlery. Some of them insisted that, as their townsman was an edge-tool maker, he ought not to have pronounced authoritatively concerning cutlery, which is a distinct branch of trade. Those who, at that time and afterwards, denied that French cutlery had risen to an equality with English, admitted that there is more grace and delicacy in the handles and the general conformation. Whatever may be the case in reference to high-class goods, it is certain that Sheffield has learned how to produce common goods at wonderfully low prices. This is effected chiefly by substituting casting and cutting-out for forging. In the processes of making the best cutlery, described in the former part of this article, cast-steel is used for the articles which are to bring the highest price. But this does not imply that the articles themselves are cast; the steel is cast into ingots, which are hammered and refined up to a high degree of excellence; and pieces of this steel are cut off, to make the articles of cutlery by forging. The cheap goods, however, are really cast; a mould is made, containing perhaps a dozen or twenty knife, or razor, or scissor patterns; and into this mould molten metal is run. The metal may be entirely iron, or principally iron with a little steel added, and is known in the trade as *run* steel. A little filing, grinding, and polishing, finishes the article, with scarcely any forging. Penknife-blades are often made by stamping a number of small oblong pieces out of a sheet of steel, and forging each separate piece into a blade. A discussion took place at the Society of Arts, on one of the evenings of meeting in 1856, concerning the light in which these goods ought to be regarded. Some of the Sheffield cutlers, then present, regretted that the cheap system had ever come amongst them. It appears that the vine-dressers of France required common and inexpensive scissors for clipping their grapes, seeing that the juice of the fruit attacked the metal, and spoiled good scissors as quickly as bad. Sheffield met the demand, and supplied such scissors at a wonderfully low price. Thereupon, some of the manufacturers determined to make such goods for the general market, to beat out all competitors by the force of cheapness; and then the markets of most countries became stocked with cutlery, which—like the razors celebrated by Goldsmith—were made to sell, not to cut. Mr. Alderman Mechi, accustomed as he is to cutlery of a high class, nevertheless would not admit that the production of cheap goods is industrially a commercial wrong—it becomes a *moral* wrong when such things are sold under false names, appearing to be what they are not. He adduced instances of table-knives and forks sold at 1*s.* 10*d.* per dozen pairs, razors at 1*s.* 6*d.* per dozen, and scissors at 2½*d.* per dozen—all of which would render *a little* service; the manufacturing of such, he contended, was not to be disapproved, unless under one or other of these two circumstances—either that the buyer sold the articles again at a much higher price, by some pretext which would for a time veil the inferiority of their quality; or that the manufacturer recklessly deprived himself of profit, or his workmen of due wages. Sheffield cutlers are, it is admitted, compelled to look sharply after each other, and after their continental rivals. The best firms have trade-marks, each firm stamping a particular mark on all the articles of cutlery made; but there are some dishonest enough to appropriate those marks, and apply them to cutlery which is thereafter sent into the market under false pretences. Some of the Sheffield mark-makers have even allowed themselves to be employed by German houses to imitate the trade-marks of eminent Sheffield cutlers—no-wise in ignorance of the purpose to which the imitative stamps were to be applied.

Of the total amount of the cutlery trade in this country, nothing definite can be stated. In the export trade, cutlery is included with hardware in the Board of Trade returns, which do not afford means for separating the items. In the years 1856–7–8, the quantities and values thus exported averaged about 715,000 cwts. annually, worth 3,813,100*l.*

Our best customer for these products is America.

CUTTING AND STABBING. [MAIM.]

CUTTING, in gardening, is a portion of a plant from which a new individual is propagated when placed in the earth. Everybody knows that a stick of willow stuck into the ground will put forth roots, and become a new plant; such an instance is a rude exemplification of the manner of multiplying plants by cuttings. In the empirical rules to be observed in this operation, the reader had better consult some book on gardening; we shall confine our observations to the theory of the operation.

Every bud which a plant contains is a distinct seat of life, capable, under fitting circumstances, of growing, flowering, fruiting, seeding, independently of all other buds, and able, if separated from the mother plant, to form a new individual. The buds of a vine, and of a potato, are actually so employed under the name of *eyes;* a cutting is merely a small collection of eyes adhering to a mass of woody matter.

A cutting, when prepared for planting, is cut off close to a bud at the bottom, and down to another at the upper end; it is then placed in earth quite up to its topmost bud, the remainder being buried. The object of this is threefold: firstly, to expose only one bud to the stimulus of light, so that when the cutting begins to grow the leaves may not, from their number, require more food than the woody system can supply; secondly, to keep back the other eyes by the pressure of the earth upon them; and thirdly, to expose as great a surface of the cutting as possible to the influence of the moist earth and darkness, by means of which the production of roots will be facilitated.

In delicate operations, where cuttings are difficult to strike, several additional practices are had recourse to. The cuttings are covered with a bell glass, in order to keep the air that surrounds them saturated with moisture, so that when the buds begin to grow they may not exhaust the cutting of its vital fluid by their excessive evaporation. They are shaded with the same object in view; sun-light increases evaporation, and stimulates a growing part into action: the desire of the gardener is to guard against this till his cuttings have formed abundant roots to feed by. When cuttings are very difficult to strike, their lower end is often made to rest upon the bottom of the garden-pot in which they are to grow; this removes their wounded end from too much moisture, and prevents their being gorged with crude sap before they are able to digest it, an evil quite as great as that of being exhausted by too rapid evaporation. The same or a similar purpose is answered by putting the cuttings in the first instance into pure silex (silver sand), from which they are removed as soon as roots are emitted; such sand permits only a slow transmission of water through it, and is in fact incapable of supersaturation if proper means are taken to drain it; and hence it renders it impossible that water should be conveyed too quickly into the open vessels of the cutting.

In many cases a single leaf, or a portion of one, is left attached to the upper eye of the cutting; this is for the sake of keeping up a slow circulation in the system, and of drawing into the vessels of the wood a gentle current of moisture, so that the cutting may never be too much exhausted.

When cuttings will not strike because they are too young, the cause is to be sought in the young tissue being too absorbent, and taking up moisture faster than it can digest it, the result of which is a repletion of the vessels, disease, and death. On the other hand, cuttings the wood of which is too old will not strike from an opposite cause; their vessels are so clogged and rigid, that when the young leaves are ready to expand, and the new roots to develop, the supply of food moves too sluggishly through the cutting from point to point, and hence the new parts wither if formed, or will not form at all. The exact age at which a cutting roots most readily is a matter of experiment, and not capable of being reduced to any theoretical rule.

It is highly probable that if these points are well considered, all plants, of whatever nature, provided they have well-formed buds, are capable of striking from cuttings; and it is notorious, that while some gardeners can only succeed with the commonest things, others, by the success that attends their operations, possess what would seem a magical power over plants, if we did not know that natural magic consists in nothing more than the right application of right knowledge at the right time.

CYAMELIDE (C_2HNO_2). A white solid substance isomeric with hydrated cyanic acid. [Cyanic acid.] It is non-crystalline, inodorous, and insoluble in water, alcohol, ether, or dilute acids. It has no acid properties. By heat it is volatilised and reconverted into hydrated cyanic acid. Hot concentrated sulphuric acid decomposes it, sulphate of ammonia is formed and carbonic acid evolved. It is not acted upon when boiled with hydrocloric or nitric acids. Heated with caustic potash, ammonia is disengaged and cyanate and cyanurate of the base formed.

CYAMELURIC ACID ($3HO, C_{12}N_7O_3$) is obtained in combination with potash on heating mellonide of potassium [Mellon] with excess of caustic potash; the salt crystallises from an aqueous solution in needles. The other *cyamelurates* are obtained by double decomposition; some of them are crystalline. Cyameluric acid may be isolated from a solution of a cyamelurate by the addition of nitric or hydrochloric acids; it then falls as a white semicrystalline precipitate. Boiled with nitric acid it gives cyanuric acid.

CYAN—CYANO, prefixes used in forming the names of certain chemical substances into the composition of which cyanogen enters. [Chlor—Chloro.]

CYANAMIDE $\left(NCyH_2 = N\left\{\begin{matrix}Cy\\H\\H\end{matrix}\right.\right)$ is best prepared by passing gaseous chloride of cyanogen into a saturated ethereal solution of ammonia (NH_3). Chloride of ammonium deposits, and the ethereal solution yields on evaporation white crystals of pure cyanamide.

Cyanamide is soluble without alteration in alcohol, and also in water, but on evaporating the aqueous solution melamine results, a compound containing three molecules of cyanamide. [Melamine.] Cyanamide fuses at 104°, and recrystallises unchanged on cooling, but if the temperature is raised to 300° it suddenly solidifies, evolves heat, and is converted into melamine. The addition of nitric acid to an ethereal solution of cyanamide causes the assimilation of two equivalents of water and formation of nitrate of urea.

If, in the above process for the preparation of cyanamide, ammonia be substituted by methylamine, ethylamine, amylamine, diethylamine, methylethylamine, &c., corresponding cyanamides are obtained, in which one or both of the equivalents of hydrogen are replaced by methyl, &c., forming monomethylcyanamide, monoethylcyanamide, diamylcyanamide, &c.; or one equivalent of hydrogen may be replaced by one radical and the other equivalent of hydrogen by another radical forming a compound cyanamide, thus methylethylcyanamide.

Cyananilide, $N\left\{\begin{matrix}C_{12}H_5\\Cy\\H\end{matrix}\right.$, is a compound similar to those just described: it is, in fact, phenylcyanamide or cyanamide in which one of the two equivalents of hydrogen is replaced by phenyl ($C_{12}H_5$). It is formed, as above indicated, by replacing the ammonia, $N\left\{\begin{matrix}H\\H\\H\end{matrix}\right.$ in the preparation of cyanamide by phenylamine (aniline) $N\left\{\begin{matrix}C_{12}H_5\\H\\H\end{matrix}\right.$. Cyananilide has not been obtained in crystals; it resembles in appearance common resin.

Two molecules of cyanamide and one of cyanic acid form ammeline [Ammeline]. One of cyanamide and two of cyanic acid form ammelide. [Ammelide].

Chlorocyanamide ($2NCyH_2, CyCl$), formed on adding solid chloride of cyanogen to solution of ammonia, contains two molecules of cyanamide and one of chloride of cyanogen.

CYANANILIDE. [Cyanamide.]

CYANATES. [Cyanic acid.]

CYANETHINE ($C_{18}H_{15}N_3$), is an organic base, polymeric with cyanide of ethyl, and containing three molecules of that body.

$$\underbrace{C_{18}H_{15}N}_{\text{Cyanethine.}} = \underbrace{3(C_4H_5, NC_2)}_{\text{Cyanide of ethyl.}}$$

Cyanethine is produced by the action of potassium on cyanide of ethyl imperfectly dried; hydride of ethyl is evolved and the residue contains cyanide of potassium and cyanethine. It crystallises from boiling water in pearly plates. Cyanethine forms salts with acids; the *nitrate* ($C_{18}H_{15}N_3, HO, NO_4$), crystallises in large colourless prisms.

CYANIC ACID ($C_2HNO_2 = CyO, HO$), is best prepared by distilling dried cyanuric acid [Cyanuric acid], the receiver being kept cool by a freezing mixture. It is a limpid colourless liquid of an exceedingly penetrating odour, resembling very strong acetic acid. It acts upon the skin as powerfully as red-hot iron, occasioning much pain. Cyanic acid is very unstable, spontaneously changing in a few hours to an opaque solid resembling porcelain. [Cyamelide.] During this change no decomposition takes place, but the molecules probably undergo rearrangement. Water converts cyanic acid into bicarbonate of ammonia.

A combination of cyanic and hydrochloric acids has been obtained by M. Wöhler. It fumes strongly in the air, and has an odour resembling a mixture of the two acids.

Cyanates are nearly all formed by double decomposition with the potash salt. *Cyanate of potash* (KO, CyO) is readily produced on adding finely powdered oxide of lead to fused cyanide of potassium:—

$$\underbrace{KCy}_{\substack{\text{Cyanide of}\\\text{potassium.}}} + \underbrace{2PbO}_{\substack{\text{Oxide of}\\\text{lead.}}} = \underbrace{KO,CyO}_{\substack{\text{Cyanate of}\\\text{potash.}}} + \underbrace{Pb_2}_{\substack{\text{Metallic}\\\text{lead.}}}$$

The metallic lead and excess of oxide sink to the bottom of the crucible and the melted mass may be poured out upon a plate. It can be purified by solution in alcohol, and obtained in crystals by evaporation. The *lead salt* (PbO, CyO) and the *silver salt* (AgO, CyO) fall as white precipitates on mixing solution of cyanate of potash with solutions of nitrate of lead or nitrate of silver.

Cyanate of ammonia (NH_4O, CyO), in solution, is after a time entirely changed into urea. [Urea.] The same transformation occurs immediately on boiling the solution. No decomposition occurs in either case. [Cyanogen.]

CYANIC AMIDE. [Cyanamide.]

CYANIC ETHER. [Ethers.]

CYANIDES. [Cyanogen.]

CYANILIC ACID ($3(HO, CyO)$, is metameric with cyanuric acid. The two acids resemble each other very closely, but the former is much more soluble than the latter. Cyanilic acid is formed on boiling hydromellon [Mellon] with nitric acid. It crystallises in efflorescent, oblique, rhomboidal prisms. Strong sulphuric acid converts it into cyanuric acid.

CYANILINE ($C_{12}H_7N, Cy$). Aniline absorbs cyanogen, and after a time deposits crystals of a basic substance capable of combining with acids like aniline itself. It is formed by the direct union of the cyanogen and aniline, and is called cyaniline. It is very slightly soluble in cold alcohol, and but little more so in boiling alcohol. It fuses at about 420° Fahr., and at a higher temperature is decomposed. Both cyaniline and its salts are very unstable.

CYANIN. MM. Fremy and Cloëz have given this name to the colouring matter that produces the red and blue tints of various flowers, the red becoming blue in the presence of an alkali, or, if the latter is in excess, assuming more or less of a green tint: in the same way an acid causes blue cyanin to assume a rose colour.

Cyanin may be obtained from the petals of the violet or iris by digestion in boiling alcohol. It has never been obtained sufficiently pure for analysis. Deoxidising agents decolorise it, and it again becomes coloured under the influence of oxygen. It is uncrystallisable. [Colouring Matters.]

CYANOGEN ($NC_2 = Cy$). A gaseous compound of the elements nitrogen and carbon, in the proportions of one equivalent of the former and two of the latter, or fourteen parts by weight of nitrogen, and twelve of carbon. It was discovered in the year 1815 by Gay Lussac, though some of its compounds were known long before that date.

Thus a beautiful blue pigment, now known to be a compound of cyanogen and iron, was accidentally discovered in Prussia, at the commencement of the 18th century, by Diesbach, and called by him *Prussian blue.* From this compound Scheele, in 1782, obtained a substance that on account of its source and properties he called *Prussic acid* (hydride of cyanogen, or hydrocyanic acid). Prussic acid was ascertained to be composed of carbon, nitrogen, and hydrogen, by Berthollet in 1787; and Gay Lussac finally determined its true constitution, and isolated cyanogen itself in 1815.

Cyanogen derives its name from two Greek words, *κύανος, blue,* and *γεννάω, to produce*, because it was first discovered in, and is an essential ingredient of, Prussian blue.

Cyanogen is exclusively a product of the animal and vegetable kingdoms. It nowhere exists free in nature. Combined with hydrogen, it occurs to a considerable extent in the juice of the bitter cassava. [CASSAVA, NAT. HIST. DIV.] The same compound of cyanogen is also produced by the decomposition of certain nitrogenised principles in fruits, when the latter are distilled with water. [AMYGDALIN.] Refuse animal matter, such as the parings of hoofs, hides, horns, &c., is the ultimate source of the many cyanogen compounds used at the present day in the arts and manufactures. These animal matters all contain nitrogen and carbon, and at a high temperature furnish cyanogen. [POTASSIUM, FERROCYANIDE OF.]

A point of considerable interest connected with cyanogen, is that it was the first discovered of those compound bodies that in their combinations and general properties so much resemble elements. Its discovery gave to organic chemistry an impetus such as it had never before received, and to which it owes no small share of its present position.

Cyanogen cannot be formed by the direct union of its elements, but is easily prepared by heating bicyanide of mercury ($Hg\,Cy_2$) [MERCURY, *Bicyanide of*] in a retort, or any other vessel from which gas may be conveniently collected.

Cyanogen is a transparent, invisible gas of a peculiar penetrating odour. It is excessively poisonous. Its specific gravity is 1·8064. It is tolerably soluble in water, much more so in alcohol, and must therefore be collected by displacement, or better over mercury. [GASES, COLLECTION OF.] It burns with a very beautiful peach-blossom coloured flame. By a pressure of several atmospheres it is condensed into a colourless liquid; and at a temperature of 30° Fahr., solidifies into a crystalline mass. It supports a very high temperature without alteration, unless iron be present, when at a full red heat it is decomposed into nitrogen gas and carbon.

Metallic cyanides, formed by the union of cyanogen with metals, may be easily prepared by indirect methods. See the various metals.

Cyanogen and *hydrogen* form only one compound.

Hydrocyanic acid ($Cy\,H$); *prussic acid.* The constituents of this acid cannot be made to unite directly, but the compound is readily formed on adding a strong acid to a metallic cyanide, cyanide of potassium for example, and may be rendered anhydrous by passing the vapour over fragments of chloride of calcium. The reaction that takes place is a simple one:—

$$\underbrace{KCy}_{\text{Cyanide of potassium.}} + \underbrace{HO,\,SO_3}_{\text{Sulphuric acid.}} \quad \underbrace{KO,\,SO_3}_{\text{Sulphate of potash.}} + \underbrace{HCy}_{\text{Hydrocyanic acid.}}$$

By cooling the receiver into which the vapour is conducted, the pure acid is obtained as a colourless transparent liquid.

Anhydrous hydrocyanic acid is very volatile, boiling at 79·7°. For this reason great care is requisite in the preparation and manipulation of it, as the inhalation of an exceedingly small quantity of the vapour rapidly destroys life. So quickly does it evaporate at common temperatures, that a drop exposed on a glass plate soon solidifies to a mass of silky fibres on account of the cold produced by volatilisation. The same effect occurs in a closed tube, on reducing its temperature by means of a freezing mixture to 5° Fahr. The vapour of this acid burns with a white flame.

Diluted hydrocyanic acid, containing two parts of the anhydrous acid to ninety-eight parts of water, is a preparation much used in medicine. Directions for preparing it of this strength are given in the 'London Pharmacopœia,' but manufacturers, to save time and expense, prepare it in a tolerably concentrated state, determine its strength by means of nitrate of silver, and then so dilute it with water that one hundred grains of the liquid shall precipitate the whole of the silver contained in a solution of 12·59 grains of pure nitrate of silver; it then constitutes the officinal preparation. The manufacture of the acid is conducted in stoneware stills or large retorts. Ferrocyanide of potassium [POTASSIUM, *Ferrocyanide of*], dissolved in water, and sulphuric acid are introduced into the still and heat applied; a strong solution of the acid distils over and is condensed in a well cooled refrigerating apparatus; the end of the stoneware worm, or condensing tube, should dip just below the surface of a little water contained in a vessel surrounded with ice. The decomposition that takes place is thus expressed:—

$$\underbrace{2(FeCy,\,2KCy)}_{\text{Ferrocyanide of potassium.}} + \underbrace{6(HO,\,SO_3)}_{\text{Sulphuric acid.}} = \underbrace{(KCy,\,2FeCy)}_{\text{Everitt's salt.}} + \underbrace{3(KO,\,HO,\,2SO_3)}_{\text{Bisulphate of potash.}} + \underbrace{3HCy}_{\text{Hydrocyanic acid.}}$$

The hydrocyanic acid prepared by this process nearly always contains a trace of sulphuric acid, but this is rather advantageous than otherwise, for when quite pure the aqueous solution of the acid is very liable to decompose, but does not do so when the smallest possible quantity of sulphuric or hydrochloric acid is present.
